The use of effective-one-body (EOB) waveforms for black hole binaries analysis in gravitational-wave astronomy requires faithful models and fast generation times. A key aspect to achieve faithfulness is the inclusion of numerical-relativity (NR) informed next-to-quasicircular corrections (NQC), dependent on the radial momentum, to the waveform and radiation reaction. A robust method to speed up the waveform generation is the post-adiabatic iteration to approximate the solution of the EOB Hamiltonian equations. In this work, we assess the performances of a fast NQC prescription in combination to the post-adiabatic method for generating multipolar gravitational waves. The outlined approach allows a consistent treatment of NQC in both the waveform and the radiation-reaction, does not require iterative procedures to achieve high faithfulness, and can be efficiently employed for parameter estimation. Comparing to 611 NR simulations, for total mass $10\mathcal{M}_\odot \leq M \leq 200\mathcal{M}_\odot$ and using the Advanced LIGO noise, the model has EOB/NR unfaithfulness well below 0.01, with 78.5\% of the cases below 0.001. We apply the model to the parameter estimation of GW150914 exploring the impact of the new NQC and of the higher modes up to $\ell = m = 8$.

I. INTRODUCTION

The continuously increasing sensitivity of gravitational-wave (GW) detectors \cite{LIGO1,LIGO2} and the associated compact binaries detections \cite{LIGO3} motivate work towards physically complete, precise and efficient gravitational-wave models. The effective-one-body (EOB) framework \cite{EOB1,EOB2} is a possible approach to state-of-art treatment for modeling waveforms from binary black holes, conceptually designed to describe the entire inspiral-merger-ringdown phenomenology of quasicircular binaries \cite{EOB3,EOB4,EOB5} or even eccentric inspirals \cite{EOB6} and hyperbolic captures \cite{EOB7,EOB8}. In the low-frequency inspiral regime, where NR simulations are not available, EOB is the only alternative to improve standard and badly convergent post-Newtonian (PN) models for exploring systematics effects in the modeling of the radiation reaction \cite{EOB9}. In the high-frequency merger regime, EOB can generate highly faithful waveforms for GW astronomy thanks to the inclusion of NR information \cite{EOB10,EOB11}. This paper focuses on a key aspect for EOB models: the consistent and efficient inclusion of NR information in the multipolar waveform.

Current EOB models are informed by NR in two separate ways: (i) on the one hand, through \textit{EOB flexibility parameters} \cite{EOB12} that allow to improve the conservative part of the dynamics, i.e. typically as effective high-order terms in the orbital, spin-orbit or spin-spin part sector of the EOB Hamiltonian; (ii) on the other hand, through next-to-quasi-circular (NQC) corrections to the multipolar waveform (and flux) \cite{EOB13,EOB14}. The latter enter as multiplicative factors, that depend on the radial motion, and correct the EOB factorized quasicircular waveform \cite{EOB15,EOB16} multipole by multipole, so to introduce effective, NR-tuned, modifications to both the amplitude and the phase. NQC corrections are essential to improve the analytical quasicircular waveform during the late plunge up to merger; they also guarantee a smooth transition to the subsequent ringdown phase. Importantly, NQC parameters are the largest set of data inferred from NR. For example, the spin-aligned TEOBResumS model uses NR information to determine 2 parameters (one orbital and one spin-orbital) \cite{EOB17} for the spin-aligned effective 5PN Hamiltonian, but 36 parameters (two for amplitude and two for phase) for the NQC-corrected multipolar waveform, that can have up to 9 multipole \cite{EOB18} completed through merger and ringdown \cite{EOB17}: $\{(\ell,|m|) = \{(2, 2), (2, 1), (3, 3), (3, 2), (3, 1), (4, 4), (4, 3), (4, 2), (5, 5)\}$. All higher modes up to $\ell = 8$ can also be optionally generated by the model, although currently without the NR-informed merger ringdown \cite{EOB19}. In the spin-aligned SEOBNRv4 \cite{EOB20} and SEOBNRv4HM \cite{EOB21} the amount of information inferred from NR is similar, although it is included differently. In particular: (i) there are 3 flexibility parameters entering the Hamiltonian \cite{EOB22} (that is different from the TEOBResumS one \cite{EOB23}); (ii) for each

\footnote{This procedure is robust as long as spins are mild, say up to $\sim 0.5$. In the nonspinning case it is even possible to complete through merger and ringdown a typically negligible mode as the $(4, 1)$. For large spins, some modes like $(2, 1)$, $(4, 3)$ or $(4, 2)$ may be inaccurate due to the delicate interplay between the strong-field dynamics and the NQC factor.}
waveform multipole there are 5 NQC parameters (3 for the amplitude and 2 for the phase)\(^2\), for a total of 25 parameters since the modes completed through merger and ringdown are \((\ell, |m|) = \{(2, 2), (2, 1), (3, 3), (4, 4), (5, 5)\} \). In addition, \texttt{SEOBNRv4HM} needs two more effective corrections to the (2, 1) and (5, 5) amplitudes that are calibrated to NR.

To achieve internal consistency between the waveform and the radiation reaction in the EOB equations of motion, the NQC amplitude factor should be also incorporated within the radiation reaction force, i.e. the flux of mechanical angular momentum. A possible approach to this problem is to iterate the dynamics several time, updating the values of NQC parameters at each step, until their values are seen to converge \cite{20, 23}. This procedure, though necessary from the physical point of view, cannot be part of a waveform generator for parameter estimation, as it would increase the global computational time at least by a factor four. Yet, it is important because, as we will see below, it also yields a fractional agreement between the NR and EOB angular momentum flux \(\lesssim 1\%\) even during the late-inspiral and plunge regime. One way out is simply to avoid this iterative procedure and keep radiation reaction without the NQC corrective factor. This route is the one implemented in \texttt{SEOBNRv4} \cite{26}, but evidently the model lacks of self consistency between radiation reaction and waveform\(^3\).

Reference \cite{13} (hereafter Paper I), shows that the (2, 2) mode of \texttt{TEOBResumS} with iterated NQC corrections achieves an overall EOB/NR unfaithfulness for total mass 10\(M_\odot \leq M \leq 200M_\odot\) is always below 0.5\%, with one single outlier grazing the 0.85\% level. \texttt{SEOBNRv4}, without the iterated NQC at most grazes 1\%, although it has been tested on only 114 spin-aligned NR waveforms \cite{20} up to \(q = 10\). This number is six time smaller than the testing sample of \texttt{TEOBResumS}, that is also pushed up to mass ratio \(q = 18\).

In this paper, we describe the NQC fitting procedure used in \texttt{TEOBResumS} in order to obtain a consistent (waveform and flux) NQC term without the iteration procedure. This NQC treatment is the default option in the most recent version of \texttt{TEOBResumS}, that incorporates higher modes \cite{13} and has been already used in \cite{20}, although not reported before. For simplicity we will refer to this version as \texttt{v2}. By contrast, the \texttt{v1} tag refers to the first implementation of \texttt{TEOBResumS} \cite{10}. We also present an updated faithfulness assessment of the \texttt{TEOBResumS} \(\ell = m = 2\) waveform against a large set of NR simulations where we include for the first time: (i) the new NQC fits; (ii) the (iterated) post-adiabatic approximation to the dynamics \cite{9, 27, 28}.

The post-adiabatic (PA) approximation is a robust method to solve the EOB Hamiltonian equations by an iterative analytical procedure rather than solving numerically the set of ODEs. The PA was shown to be crucial for parameter estimation with \texttt{TEOBResumS}, both for black holes and neutron stars \cite{18, 29, 51}. In particular, the PA is a simple, flexible and robust alternative to surrogate methods \cite{32, 33}. By using this approach, the dynamics computation can become up to 20 times faster and its employment is among the reasons why the \texttt{TEOBResumS} computational cost is generally one order of magnitude smaller than the \texttt{SEOBNRv4HM} \cite{11} one. This method is implemented in the most recent stand-alone release of \texttt{TEOBResumS} as well as in the \texttt{v1} release within the LIGO Algorithm Library (LAL) \cite{34}. We demonstrate the use of the NQC fits and of the PA approximation in parameter estimation on GW150914, notably using the multipolar waveform with all modes up to \(\ell = m = 8\). In particular, the possibility of doing PE with and without NQC fits allows us to analyze in detail a very specific source of analytical systematics in waveform modeling.

This paper is organized as follows. Section \textbf{II} reviews the motivations and structure of the NQC correction and the new fits. Sec. \textbf{III} discusses the validation of the production setup of \texttt{TEOBResumS} with the new NQCs and the PA against 595 SXS and 19 BAM waveforms. In Sec. \textbf{IV} we give an account of the \texttt{TEOBResumS} waveform generation time. Finally, Sec. \textbf{V} presents the application to GW150914 analysis. After the conclusions, the paper has two appendices: Appendix \textbf{A} reports the unfaithfulness plots of Paper I to facilitate the comparison with the new results; Appendix \textbf{B} contains all the details on the new NQC fits.

\section{EOB Next-to-Quasicircular Corrections}

Next-to-quasi-circular corrections were introduced in the first EOB analysis of the transition from inspiral to plunge, merger and ringdown in the test-particle limit \cite{20}. They were originally conceived as an effective noncircular correction to the flux of mechanical angular momentum \(F_\psi\), so to consistently model it during the plunge up to merger (see Fig. 2 in Ref. \cite{20}). In subsequent EOB/NR works \cite{21, 22} they were moved to the (2, 2) waveform in order to achieve an optimal EOB/NR amplitude and phase agreement at merger and ease the attachment of the ringdown part. Finally, Ref. \cite{23} introduced the current paradigm, within \texttt{TEOBResumS}, of having them in both the (2, 2) waveform and radiation reaction, with the iterative procedure to consistently determine the effective NQC parameters entering the (2, 2) amplitude. More precisely, each factorized and resummed \cite{24} EOB waveform mode \((\ell, m)\) is dressed by

\begin{itemize}
  \item \textbf{II.} EOB Next-to-Quasicircular Corrections

Next-to-quasi-circular corrections were introduced in the first EOB analysis of the transition from inspiral to plunge, merger and ringdown in the test-particle limit \cite{20}. They were originally conceived as an effective noncircular correction to the flux of mechanical angular momentum \(F_\psi\), so to consistently model it during the plunge up to merger (see Fig. 2 in Ref. \cite{20}). In subsequent EOB/NR works \cite{21, 22} they were moved to the (2, 2) waveform in order to achieve an optimal EOB/NR amplitude and phase agreement at merger and ease the attachment of the ringdown part. Finally, Ref. \cite{23} introduced the current paradigm, within \texttt{TEOBResumS}, of having them in both the (2, 2) waveform and radiation reaction, with the iterative procedure to consistently determine the effective NQC parameters entering the (2, 2) amplitude. More precisely, each factorized and resummed \cite{24} EOB waveform mode \((\ell, m)\) is dressed by

\end{itemize}
a multiplicative contribution $\hat{h}_{\ell m}^{\text{NQC}}$ as

$$h_{\ell m} = h_{\ell m}^{(N,c)} \hat{h}_{\ell m} \hat{h}_{\ell m}^{\text{NQC}}, \quad (1)$$

where $h_{\ell m}^{(N,c)}$ is the Newtonian prefactor with parity $c$ and $\hat{h}_{\ell m}$ the relativistic correction. The NQC factor is parametrized by four parameters $(a_1^{\ell m}, a_2^{\ell m}, b_1^{\ell m}, b_2^{\ell m})$:

$$\hat{h}_{\ell m}^{\text{NQC}} = \left( 1 + a_1^{\ell m} n_1^{\ell m} + a_2^{\ell m} n_2^{\ell m} \right) \times e^{i b_1^{\ell m} n_3^{\ell m} + i b_2^{\ell m} n_4^{\ell m}}, \quad (2)$$

where $n_i^{\ell m}$ are functions depending on the radial velocity and acceleration, see Eqs.(3.32)-(3.35) of [12] and Ref. [28]. Parameters $(a_1^{\ell m}, a_2^{\ell m})$ determine the NQC of the amplitude’s multipole $(\ell, m)$, while $(b_1^{\ell m}, b_2^{\ell m})$ determine the NQC to the phase and frequency of the multipole $(\ell, m)$. The parameters $(a_1^{(2,2)}, a_2^{(2,2)})$ play a special role as they are also included in the radiation reaction [23]. Their best values are determined by an iterative procedure, e.g. the one of Paper I. The parameters $(a_1^{(\ell, m)}, a_2^{(\ell, m)})$ with $(\ell, m) \neq (2, 2)$ are instead best generated by solving a set of four coupled algebraic equations and imposing NR-informed fits of amplitude, frequency and their first derivatives around merger [10, 12, 13, 23, 28, 35].

A. Fitting NQC parameters $(a_1^{(2,2)}, a_2^{(2,2)})$

The high NR-faithfulness of TEOBResumS in Paper I depends on the EOB flexibility functions $(a_0^0, c_3)$ that are NR-informed under the conditions that $(a_1^{(2,2)}, a_2^{(2,2)})$ are determined from the iterative procedure. Dropping this would imply a worsening of the global EOB/NR agreement (see below). As a consequence, we need to construct accurate fits of $(a_1^{(2,2)}, a_2^{(2,2)})$ all over the parameter space so to obtain EOB/NR unfaithfulness similar to the iterative procedure while not requiring iterations. To do so, we proceed as follows. First, the parameters $(a_1^{(2,2)}, a_2^{(2,2)})$ are determined with the same iterative procedure of Paper I for 2291 simulations up to mass-ratio of $q = 30$ with aligned spins up to $\chi_1 = \chi_2 = \pm 0.99$. Second, the values $(a_1^{(2,2)}, a_2^{(2,2)})$ are fitted across the parameter space. The latter is divided in four different regions:

(i) Nonspinning sector, $\chi_1 = \chi_2 = 0$
(ii) Spinning sector, equal-mass sector with $\nu > 0.2485$
(iii) Spinning sector, $0.16 \leq \nu < 0.2485$
(iv) Spinning sector, with $\nu \leq 0.16$.

In each region different templates are employed to better capture the functional behavior of $(a_1^{(2,2)}, a_2^{(2,2)})$. All fits are done using as single spin parameter the standard spin combination

$$\hat{S} \equiv \frac{S_1 + S_2}{M^2} = X_1^2 \chi_1 + X_2^2 \chi_2,$$  \quad (3)
where $S_i$ are the dimensionful individual spins, $x_i \equiv S_i/m_i^2$ are the dimensionless spins and $X_i \equiv m_i/M$. The spin parameter $\tilde{S}$ is actually used in the fits only for the equal-mass case. In the other situations, it looks more flexible to incorporate some $\nu$-dependence and use instead

$$\tilde{S}_\nu \equiv \frac{\tilde{S}}{1 - 2\nu^2}. \quad (4)$$

All the details of the fitting procedure are in Appendix B.

Our NQC implementation has been extensively tested to check its robustness all over the parameter space. Fig. 1 illustrates that the new NQC implementation never failed for 420,000 binary configurations drawn from random distributions of spins $-1 < a_0 < +1$ and mass ratios $1 \leq q \leq 1000$. The EOB runs in the figure are generated with the PA method, computing the dynamics up to the dimensionless radius $r = R/GM = 14$ on a grid with $dr = 0.1$ using the 8th PA order [9]. The other NR-informed EOB parameters are the same as in [13] and corresponds to the default configuration of TEOBResumS for parameter estimation.

### B. Examples: EOBNR phasing and fluxes with and without NQC corrections

Before producing EOB/NR comparisons over the full database of NR simulations used in Paper I, let us discuss the effect of the various NQC choices on an illustrative example. We choose configuration $(2, +0.85, +0.85)$, corresponding to SXS:BBH:0257-TEOBResumS waveforms corresponding to this binary are generated with three distinct options for NQC: (i) the iterative procedure of Paper I (here used with 4 iterations); (ii) the new fits of Sec. II A; (iii) the absence of NQC parameters in the flux. Figure 2 illustrates the EOB/NR phase difference $\Delta \phi_{EOB,NR} \equiv \phi_{EOB} - \phi_{NR}$. For these three cases, plotted versus dimensionless time $t \equiv T/M$. The NQC parameters are typically of order unity, consistently with what pointed out in the test-mass limit (see in particular discussion around Eq. (12) of Ref. [20]). For the iterated case, we have $(a_1^{(2)}, a_2^{(2)}) = (0.09, 1.2917)$, while the fit consistently yields $-0.2368, 1.1964$. The EOB waveforms are aligned to the NR one by choosing relative time and phase shifts so to minimize the phase difference on the dimensionless gravitational wave frequency interval $[\bar{f}_{1-3}, \bar{f}_{2-4}] = [0.034, 0.045]$. The corresponding temporal interval is indicated by the dash-dotted vertical lines in the left panel of the plot. The fitted NQC parameters deliver a waveform that is perfectly consistent (though not strictly identical) with the one obtained via the iterative procedure. For each one of the three cases, the maximum EOB/NR unfaithfulness $\max(\tilde{F})$ computed in the next section using Eq. (5) is 0.414%, 0.456% and 1.7%. Note that this last number corresponds to an accumulated phase difference $\sim 4$ rad around merger time.

The presence of iterated NQC correction is also essential to yield consistency between the NR angular momentum flux and the EOB flux, i.e. the radiation reaction force, with the opposite sign, that drives the inspiral dynamics. Figure 3 demonstrates this fact for a specific dataset. A more detailed and systematic analysis will be discussed elsewhere [30]. To our knowledge, this is the first EOB/NR flux comparison after earlier work [37]. This analysis is essential to cross check the reliability of radiation reaction, an approach that is well consolidated in the test-particle limit [20, 35, 40]. For comparable masses, it has never been exploited systematically because of the difficulty of computing it accurately.

---

4 This variable, called $\chi$, is used in various fits of merger and post-merger quantities entering the SEOBNRv4 model [20].
FIG. 4. EOB/NR unfaithfulness for the $\ell = m = 2$ mode using all currently available spin-aligned SXS NR simulations and a bunch of BAM simulations. Top row: TEOBResumS with the PA approximation for the inspiral and without NQC corrections in radiation reaction. Bottom row: TEOBResumS with the PA approximation for the inspiral and with the NQC parameters obtained by the fit in radiation reaction. From left to right, the columns use the following NR data: SXS spin-aligned waveforms publicly released before February 3, 2019; SXS spin-aligned waveforms publicly released after February 3, 2019; spin-aligned BAM data; nonspinning configurations. The quality of the EOB performance with the NQC fits is very good and essentially equivalent to the outcome of the exact iterative procedure of Ref. [13], that is reported in Fig. 11 in Appendix for completeness.

FIG. 5. Summary histogram of EOB/NR unfaithfulness $\tilde{F}_{\text{EOB/NR}}$ over the full NR database of 611 simulations, without NQC fits (top panel) and with fits (bottom panel). The various SXS subsets, nonspinning (black online, 89 waveforms), merger-ringdown calibration (blue online, 116 spin-aligned waveforms) and validation (red online, 388 spin-aligned waveform) as defined in Paper I are presented separately. The plot shows the fraction (expressed in %) $n/N_{\text{set}}$, where $N_{\text{set}}$ is the total number of waveforms in a given NR-waveform set and $n$ is the number of waveforms, in the same set, that, given a value $\tilde{F}$, have $F_{\text{EOB/NR}} \geq \tilde{F}$. The colored marker highlight the largest values in each NR dataset.

From NR simulations [37]. Figure 5 demonstrates that, at least for the most recent SXS datasets, this is actually possible. The top panel of the figure shows Newton-normalized angular momentum fluxes, while the bottom panel the EOB/NR fractional differences. Specifically, we use $F_{\text{NR}} = 32/5x^{3/2}$, where we define the frequency parameter from the GW quadrupole frequency $\omega_{22}$ as $x \equiv (\omega_{22}/2)^{2/3}$. Note that $\omega_{22} = \omega_{22}^{\text{EOB/NR}}$ in the EOB or NR case. The figure reports: (i) the raw NR angular momentum flux summed over all multipoles up to $\ell_{\text{max}} = 8$; (ii) the smoothed one, where the high-frequency noise (see inset) related to residual eccentricity and extrapolation has been eliminated with a specific fitting procedure [36]; (iii) the EOB flux, summed up to $\ell_{\text{max}} = 8$, with the iterated NQC correction factor in the flux, as described in Ref. [23]; (iv) the same without the NQC correction factor. The top panel of Fig. 5 also display the 3.5 PN accurate Taylor expanded flux along circular orbits. The vertical lines mark the EOB
TABLE I. GW190514 analysis and main parameters intervals. We report the median and 90% credible region for the parameters extracted from the posterior distribution. Explicitly, the total mass $M$, the chirp mass $M_{\text{c}}$, the individual masses $m_1$, the mass ratio $q$, the dimensionless spins $\chi_i \equiv S_i/m_i^2$ and their combination $\chi_{\text{eff}} = \bar{a}_0 = (m_1 \chi_1 + m_2 \chi_2)/M$, the luminosity distance $D_L$, the inclination angle $i$, the right ascension $\alpha$ and declination $\delta$. In the last row, we show the logarithmic Bayes’ factor with its standard deviation.

Last Stable Orbit (LSO) as well as the location of the NR merger. It is important to note that this comparison does not depend on an arbitrary time and phase shift (as it happens in waveform comparisons). It is an intrinsic observable, complementary to the energy/angular momentum curves, that in principle could be used to improve the current knowledge of the resummed analytical flux. When looking at fractional differences (bottom panel) one sees that the inclusion of NR-informed QNC corrections in the flux yields a EOB/NR agreement at the level of the NR uncertainty up to the LSO location. The uncertainty on the NR data is obtained, as usual, by taking the fractional difference between the highest and second highest resolutions available. Incorporating NR-informed QNC corrections in the flux is thus an essential building element of TEOBResumS, since it guarantees the physical correctness of the (self-consistent) EOB dynamics driven by radiation reaction.

III. EOB/NR UNFAITHFULNESS

Paper I assessed the quality of the $(2,2)$ mode of TEOBResumS by comparing it to a total set of 595 SXS and 19 BAM waveforms. Each EOB waveform was generated using 4 to 5 iterations. The overall comparison was done computing the EOB/NR unfaithfulness $\bar{F}(M)$ as a function of the total mass $M$. The unfaithfulness $\bar{F}$ between two waveforms $(h_1, h_2)$ is defined by

$$\bar{F} \equiv 1 - F = 1 - \max_{t, \phi_c} \frac{(h_1, h_2)}{\sqrt{(h_1, h_1)(h_2, h_2)}},$$

where $t_c$ and $\phi_c$ denote the time and phase at coalescence, and the Wiener scalar product associated to the power-spectral density (PSD) of the detector, $S_n(f)$, is $(h_1, h_2) := 4 \int_{f_{\text{min}}}^{f_{\text{max}}} df |\tilde{h}_1(f)| |\tilde{h}_2(f)|/S_n(f)$, where $\tilde{h}_1(f)$ is the Fourier transform of $h_1(t)$. For the computation of EOB/NR unfaithfulness we use $f_{\text{min}}$ as the minimum NR frequency, and the Advanced LIGO PSD.

The full EOB/NR unfaithfulness calculations of Paper I was shown in Figs. 3 and 4 therein (and it is shown again in Fig. 1 for completeness): it is always below 0.5% except for a single outlier that reaches the 0.85%. Here we repeat such calculation, but with important differences: (i) we use the fits determined in the section above for $(a_1^{(2,2)}, a_2^{(2,2)})$, so that we do not have to iterate on the dynamics but still we have an improved consistency between the waveform and the flux; (ii) we use the post-adiabatic approximation to efficiently compute the inspiral part. The PA dynamics is computed at the 8th PA order on a grid with separation $d\tau = 0.1$ and stops at $r = 14$. The other EOB parameters are the same as in Paper I and corresponds to the default configuration of TEOBResumS for parameter estimation. In addition we also compute $\bar{F}$ without the QNC correction in the flux. The results are summarized in Fig. 1 without fits in the top row and with fits in the bottom row. Each figure collects four panels that refer to different subsets of the NR simulations available, separated according to the convenient classification of Paper I. From left to right, each column of the figure uses: spin-aligned SXS waveforms publicly released before February 3, 2019; spin-aligned SXS waveform data publicly released after February 3, 2019; spin-aligned BAM data; nonspinning SXS and BAM data, up
to mass ratio $q = 18$. The absence of the NQC corrections in radiation reaction increases $\max(\dot{F})$ up to (a still acceptable) $\sim 3\%$; by contrast, when the NQC fits are included one easily gets $\max(\dot{F})$ well below $1\%$, consistently with the results of the iteration. The global picture is summarized in Fig. 5 that highlights in a single figure the improvement brought by the fits.

IV. COMPUTATIONAL EFFICIENCY

In this Section we show the performance of TEOBResumS using the PA approximation [2]. The latter is used to avoid part of the computation of Hamilton’s equations, that in the case of a nonprecessing system consist of 4 ordinary differential equations (ODEs). Its use can be extended to any EOB-based model, as shown in Sec. VI of Ref. [27]. Within TEOBResumS, the 8th PA order is generally used to compute the radial and angular momenta on a radial grid, starting at the initial radius $r_0$, ending at dimensionless separation $r = 14$, with step $dr = 0.1$. The other two dynamical variables, time and phase, are then calculated through an integration on the radial grid, essentially halving the number of necessary integrations. Beyond $r = 14$ the approximation could become unreliable for certain configurations and hence
the full ODEs are solved in the usual way. The computational gain of using the PA approximation to compute full waveforms is preliminarily discussed in Appendices of Refs. [30, 44], we present here a more detailed set of results.

In Fig. 6 we show the TEOBResumS waveform generation time and the speedup with respect to configurations when the 4 ODEs are solved for the whole evolution. As expected, the use of the PA approximation has a greater impact on longer waveforms (lower total mass). We can also note that, even without this speedup, TEOBResumS is already fast in the context of EOB-based models.

To put these times into perspective, in Fig. 7 we compare TEOBResumS to its equivalent higher modes model of the SEOBNR family, SEOBNRv4HM [11, 26]. This latter is implemented within the LIGO Algorithm Library (LAL) [34] and, the time of writing, does not employ the PA approximation. The C implementation of TEOBResumS, denoted v2, is run with different settings: using all the modes up to \( \ell = 8 \) or just the dominant \( \ell = m = 2 \) one; employing the PA approximation for the dynamics or solving the full ODEs. These are compared to the LAL version of SEOBNRv4HM and of the same TEOBResumS. This older iteration, the TEOBResumS v1, already employed the PA approximation, but did not include higher modes nor NQC corrections in the flux. As we can expect, models which only include the \( \ell = m = 2 \) multipole are found to be faster. At the same time, we can see that the PA approximation (that is never employed in TEOBResumS when systems would start at \( r_0 < 14 \)) improves the performance for long waveforms. When compared to SEOBNRv4HM, we find that TEOBResumS is generally an order of magnitude faster.

We highlight that, in order to improve the SEOBNRv4HM performances, a reduced order model in the frequency domain has been developed [33], that accelerates the waveform generation time by a factor of 100-200. In a similar effort, Ref. [15] has recently applied machine learning methods to both TEOBResumS and SEOBNRv4 [26] and built time-domain models that achieve a speedup of 10 to 50 for TEOBResumS and about an order of magnitude more for SEOBNRv4, see Fig. 7 of Ref. [15]. This fact is consistent with our analysis of Fig. 7; it reflects the difference in computational cost of the two baseline models.

In conclusion, our timing analysis indicates that the native implementation of TEOBResumS using the PA approximation (including the v1 implementation distributed with LAL [34]) is efficient enough to be used for parameter estimation, as we shall demonstrate in the following section.

---

5 For simplicity, we ended the PA at \( r = 14 \) as a robust, conservative, choice all over the parameter space. This limit could actually be fine tuned as a function of the binary spin content and lowered below \( r = 10 \).

6 For a comparison of the two models differences in the conservative dynamics, and the application of the PA approximation to SEOBNRv4, see Ref. [22].

V. GW150914 ANALYSIS

We ran a PE study on GW150914 using bajes [29]. We employed the dynesty sampler with 1024 live points and tolerance of 0.1. We extracted the data from the GWOSC archive [46] and analyzed 16 seconds of data around GPS time 1126259462, with a sampling rate of 4096 Hz in the range of frequencies \([20, 1024]\) Hz. We set the same prior distributions for all runs. The chirp mass prior was uniform in \([24, 37]\) M$_\odot$ and the mass ratio \( q \) in \([1, 8]\). We only considered aligned spins with an isotropic prior in the range \([-0.99, +0.99]\). We used a volumetric prior for the luminosity distance in \([100, 800]\) Mpc.

Separate runs are performed with TEOBResumS, either including the new NQC fits in the radiation reaction or not. For each of the two cases, parameter estimation runs are performed with the (2, 2) mode only (22), the \( \ell = m \) and \( \ell \leq 5 \) modes (LM), and with all the modes up to \( \ell = m = 8 \) multipoles (HM). In this case, all the other subdominant modes except \( (2, 1) \), \( (3, 2), (4, 3) \) and \( (4, 2) \) do not use NR information to be completed through merger and ringdown, but only rely on the analytical EOB waveform (see e.g., Fig. 10 of Ref. [12]). We used the PA approximation of the dynamics for all runs, as it is the default option for our implementation (e.g., [18, 29, 31]). Each one of these analyses took about 2 days on 8 CPUs. More details on the TEOBResumS computational cost can be found in Appendix IV.

The results of such runs are listed in Table VI. The difference of using the NQC fits is highlighted in Fig. 8. Neglecting the NQC fits in the radiation reaction, that has a large impact on the EOB-NR unfaithfulness, has a very small effect on parameter estimation, despite the high SNR of GW150914. The only appreciable difference can be seen in the \( \chi_{nr} \) variable for the 22 run, which is more skewed towards 0 when NQC fits are used. It is interesting to note that the difference between using the NQC fits and not employing them tends to disappear when using more multipoles. Some effect in this direction was to be expected, since the NQC fits only affect the \( \ell = m = 2 \) mode, which has a somewhat diminished importance when other multipoles are used.

Using the same data, we can attempt to determine whether this analysis is sensitive to the higher modes, given that the system is almost equal-mass and nonspinning. There are no appreciable differences in the system parameters when using higher order multipoles, apart from a small preference for a mass ratio closer to 1. Instead, using modes beyond the dominant \( \ell = m = 2 \) one, helps to better constrain the source distance and inclination. In particular, the runs which employed a larger number of modes, seem to prefer larger distances and more face-on/away configuration. These results are compatible with what found in Ref. [47] using the NR surrogates NRSur7dq2 and NRSur7dq2HM. This difference in posteriors is shown in Figs. 9 and 10.

We conclude highlighting that using Bayes’ factors, we cannot determine a preference for any of the models used
for these analyses (see again Table I).

**VI. CONCLUSION**

This work completes the description of the techniques employed in the current TEOBResumS waveform (v2) [10, 13] and outlines a viable path towards the use of faithful EOB models in GW parameter estimation. Here, we highlighted the importance of: (i) including NQC corrections in the radiation reaction and (ii) using the post-adiabatic approximation to improve the computational efficiency of the inspiral.

The NQC fits developed here ensure an improved consistency between the EOB dynamics (radiation reaction flux) and the waveform without the need of an iterative procedure to determine the NQC parameters \(a_1^{(2,2)}, a_2^{(2,2)}\). The EOB/NR unfaithfulness achieved with this NQC setting and with the use of the post-adiabatic approximation to the EOB dynamics is always below 0.01, with 78.5% of the 611 NR waveforms below 0.001 (see right panel of Fig. 5).

The PA approximation, together with an efficient implementation, makes each version of TEOBResumS (including v1 distributed with LAL [34]) suitable for parameter estimation of GW150914. Comparing parameter inference with and without NQC fits. It is interesting to note that the effect of the NQC is highly subdominant when all the higher modes up to \(\ell = 8\) are included in the waveform.
estimation in its native form, without the need of constructing surrogate or machine learning representations. The latter can provide significant further speed up \cite{15}, but their construction becomes increasingly more complex as more physics effects are included (spin precession, eccentricity, etc).

The application of TEOBResumS to GW150914, that still represents one of the highest signal-to-noise ratio event observed thus far, indicates that the present techniques are well suited for the unbiased analysis of comparable-masses and moderately spinning binary black holes signals. In particular, the analysis is not sensitive to the inclusion of NQC fits in the radiation reaction, despite the inconsistency and far worse EOB/NR unfaithfulness of the model when these fits are not included. The inclusion of higher modes beyond the $\ell = m = 2$ one has an appreciable effect only in giving a more stringent constraint of the source distance and inclination, as also seen with NR surrogates \cite{47}.

Future work should address the waveform systematics effects and limitation of current EOB models for larger mass-ratio and/or waveforms with larger spins. An important aspect in this respect, is to explore phasing, faithfulness and full parameter estimation altogether, as done for tidal effects in \cite{18}, in order to identify which elements of the model require improvements and the connection between the phasing and the parameter estimation.

The current techniques can be immediately applied to include precessional effects \cite{18} and tides \cite{44, 49}; fast post-adiabatic multipolar waveforms with these features can be already generated with TEOBResumS. The same computationally efficient infrastructure of TEOBResumS is also shared by TEOBResumSGeneral \cite{16, 17, 50}, that deals with either eccentric inspirals (although without the PA approximation) or hyperbolic scatterings. Future work will also focus on rapid, and yet accurate, methods for the solution of the eccentric EOB dynamics \cite{16, 17, 50}, and on the extension of EOB to directly compute frequency-domain inspiral-merger-ringdown waveforms \cite{31}.

Appendix A: NR faithfulnesses with NQC iterations

This appendix reports for completeness the faithfulness published in Ref. [13] (Paper I) and obtained with the iterative NQC procedure and the full ODE integration. The plots are shown in Fig. [1] and can be directly compared to those shown in Fig. [4] in the main text, that are instead obtained with the fits for the NQC parameters \((a_1^2, a_2^2)\) entering the radiation reaction and the PA approximation to the numerical solution of the EOB Hamilton’s equations during the inspiral. The unfaithfulness plots are obtained using the most recent realization of the zero-detuned, high-power noise spectral density of Advanced LIGO [51].

Appendix B: NQC fits of \((a_1^{2,2}, a_2^{2,2})\)

This appendix summarizes the NQC fits performed in this work. The fits are performed hierarchically in different sectors of the parameter. All fits have been performed with ftnlm of Matlab. The superscript \((2,2)\) is dropped in the notation in this appendix.

1. Non-spinning sector

The fits in the non-spinning sector are obtained with a total of 27 waveforms, for mass-ratios \(1 \leq q \leq 30\). The coefficient \(a_1\) is fitted against \(X_{12}^2 = (1 - 4\nu)^2\) with the template

\[
a_1 = \frac{a_1^{q=1}}{1 + b_1^1 X_{12}^2 + b_2^1 X_{12}^4}
\]  

with

\[
a_1^{q=1} = 0.070974
b_1^1 = 0.786350
b_2^1 = -9.085105 .
\]

The value of \(a_1^{q=1}\) is extracted from \(q = 1\) NR data.

The coefficient \(a_2\) in the non-spinning sector is fitted against \(X_{12} = \sqrt{1 - 4\nu}\) with the template

\[
a_2 = \frac{a_2^{q=1} + b_4^2 X_{12}}{1 + b_5^5 X_{12}}
\]  

with

\[
a_2^{q=1} = 1.315133
b_4^2 = -0.324849
b_5^5 = -0.304506
b_6^6 = -0.371614 .
\]

The value of \(a_2^{q=1}\) is extracted from \(q = 1\) NR data.

2. Equal-mass sector

Equal-mass data are defined by \(\nu > 0.2485\). A total of 40 waveforms with spins \(-0.98 \leq \chi_{1,2} \leq 0.99\) are used to obtain the fits of the equal-mass region. The coefficient \(a_1\) in the equal-mass cases is fitted with the template:

\[
a_1 = \frac{a_0^1 + a_1^1 \hat{S} + a_2^1 \hat{S}^2 + a_3^1 \hat{S}^3 + a_4^1 \hat{S}^4 + a_5^1 \hat{S}^5 + a_6^1 \hat{S}^6}{1 + c_0^1 \hat{S} + c_1^1 \hat{S}^2 + c_2^1 \hat{S}^3 + c_4^1 \hat{S}^4} .
\]  

with the coefficients:

\[
a_0^1 = 0.121187
a_1^1 = -5.950663
a_2^1 = 9.420324
a_3^1 = -10.601339
a_4^1 = 17.641549
a_5^1 = -5.684777
a_6^1 = 10.910451
\]

\[
c_0^1 = -5.950663
c_1^1 = -10.601339
c_2^1 = -5.684777
c_4^1 = -6.867377 .
\]
The coefficient $a_2$ is fitted to the same template. The fitted coefficients are:

\[
\begin{align*}
c_0^a &= 1.331703 \\
c_2^a &= 1.786023 \\
c_4^a &= -9.698233 \\
c_6^a &= 13.209381
\end{align*}
\]

The fitted coefficients $c_n^a$ are:

\[
\begin{align*}
&d_4^a = -3.082861 \\
d_6^a = -0.636353 \\
d_8^a = -2.843896 \\
d_{10}^a = -0.832894 \\
&d_4^{\hat{a}} = 2.169948 \\
&d_6^{\hat{a}} = 0.741419 \\
&d_8^{\hat{a}} = 2.709697 \\
&d_{10}^{\hat{a}} = .
\end{align*}
\]

3. Sector with mass ratio $1 < q < 4$

In this sector the fit of $a_1$ differs in two ways from the previous: (i) the fit is factorized in a spinning part $a_1^S$ and a non-spinning part $a_1^0$, and (ii) the fit uses the spin variable $\hat{S}_\nu \equiv \hat{S}/(1 - 2\nu)$. The full template is:

\[
\begin{align*}
a_1 &= a_1^0 \cdot a_1^S, \\
&= d_0^a + d_1^a \nu + d_2^a \nu^3 \\
&\frac{1 + d_3^a \nu}{1 + d_3^a \nu}, \\
&= 1 + d_4^a \hat{S}_\nu + d_5^a \hat{S}_\nu^2 + d_6^a \hat{S}_\nu^3 + d_7^a \hat{S}_\nu^4.
\end{align*}
\]

The fitted coefficients take the values of $a_1^I$ are:

\[
\begin{align*}
d_0^{a} &= 0.26132647 \\
d_1^{a} &= -4.90302367 \\
d_2^{a} &= 20.67036124 \\
d_3^{a} &= -3.17109808
\end{align*}
\]

Note these coefficients are fitted to waveforms for which $\chi_2 = \pm 0.01$ and $\chi_1$ is chosen such that $\hat{S}_\nu = 0$. This approach is taken also for all of the following non-spinning factor fits. In total 70 waveforms with $\hat{S}_\nu = 0$ and further 454 with spin $-0.9 < \chi_{1,2} \leq 0.99$. Of these 160 are focused on the high region, $0.8 \leq \chi_{1,2} \leq 0.99$.

The fitted coefficients of $a_2^I$ are:

\[
\begin{align*}
d_4^a &= -3.082861 \\
d_6^a &= -0.636353 \\
d_8^a &= -2.843896 \\
d_{10}^a &= -0.832894 \\
d_4^{\hat{a}} &= 2.169948 \\
d_6^{\hat{a}} &= 0.741419 \\
d_8^{\hat{a}} &= 2.709697 \\
d_{10}^{\hat{a}} &= .
\end{align*}
\]

The coefficient $a_2$ is fitted in a factorized form as well. Additionally, it holds an explicit dependency of $a_2^S$ on $\nu$:

\[
\begin{align*}
a_2 &= a_2^0 \cdot a_2^S, \\
a_2^0 &= d_0^a + d_1^a \nu + d_2^a \nu^3 \\
&\frac{1 + d_3^a \nu}{1 + d_3^a \nu}, \\
a_2^S &= 1 + d_4^a \hat{S}_\nu + d_5^a \hat{S}_\nu^2 + d_6^a \hat{S}_\nu^3 + d_7^a \hat{S}_\nu^4.
\end{align*}
\]

The fitted coefficients of $a_2^S$ are:

\[
\begin{align*}
d_0^{a} &= 1.03364144 \\
d_2^{a} &= -7.86652243 \\
d_4^{a} &= -8.96268815
\end{align*}
\]

The fitted coefficients of $a_2^0$ are:

\[
\begin{align*}
d_4^{a,0} &= 0.036452 \\
d_6^{a,0} &= 0.275707 \\
d_8^{a,0} &= -0.113951 \\
d_{10}^{a,0} &= -2.531304 \\
d_{12}^{a,0} &= -1.025824 \\
d_{14}^{a,0} &= 0.593579 \\
d_{16}^{a,0} &= -0.939736
\end{align*}
\]

$d_{18}^{a,0}$ is set to 0 prior to the evaluation of the fit to improve the convergence of the fit.
4. Sector with mass ratio \( q \geq 4 \)

For the following fits a similar approach to was taken as above. A total of 44 with \( S_i = 0 \) have been generated. 186 waveforms with \(-0.99 \leq \chi_{1.2} \leq 0.99\) have been used to capture the \( q = 4 \) behavior accurately. 1470 further waveforms with \(-0.99 \leq \chi_{1.2} \leq 0.85\) have been used to fit the extrapolation of the \( q = 4 \) fit up to mass ratio \( q = 30 \). The coefficient \( a_1 \) for \( q \geq 4 \) has an additional feature. The explicit \( \nu \) dependence is fitted through \( x_\nu = \nu - 0.16 \). The full template is:

\[
\begin{align*}
a_1 &= a_0^1 \cdot a_2^S, \\
a_0^i &= c_0^1 \left[ 1 + c_0^{a_1} \nu + c_0^{a_2} \nu^3 \right] , \\
a_2^S &= \frac{1 + c_2^{a_1} S_\nu + c_2^{a_2} S_\nu^2 + c_2^{a_3} S_\nu^3 + c_2^{a_4} S_\nu^4}{1 + c_3^{a_1} S_\nu} , \\
e_i &= c_i^1 \left[ 1 + c_2^{a_1} x_\nu \right], \quad \text{for } i = 4, \ldots, 10 .
\end{align*}
\]

The fitted \( a_0^i \) coefficients are:

\[
\begin{align*}
e_0^1 &= 0.341803 , & e_1^1 &= -1.350488 , \\
e_2^1 &= -6.353357 , & e_3^1 &= 2.216156 .
\end{align*}
\]

The coefficients of \( a_2^S \) are fitted in 2 steps. First, for \( q = 4 \) and second, an extrapolated fit from there. The coefficients \( e_i^{a_2} \) are fitted to \( q = 4 \):

\[
\begin{align*}
e_1^{a_2} &= -2.287721 , & e_5^{a_2} &= -0.598451 , \\
e_6^{a_2} &= 0.766069 , & e_7^{a_2} &= 1.857169 , \\
e_8^{a_2} &= -2.035234 , & e_9^{a_2} &= 0.836427 , \\
e_{10}^{a_2} &= 0.297476 .
\end{align*}
\]

The remaining coefficients model the extrapolation of the spin dependence to larger mass ratios and are:

\[
\begin{align*}
e_4^{a_2} &= 7.650946 , & e_5^{a_2} &= 7.106992 , \\
e_5^{a_1} &= -60.630748 , & e_5^{a_2} &= -69.630357 , \\
e_6^{a_1} &= 47.114247 , & e_6^{a_1} &= 5.733002 , \\
e_7^{a_1} &= -12.905797 , & e_7^{a_1} &= 5.045688 , \\
e_8^{a_1} &= 3.515869 , & e_8^{a_1} &= 1.564146 , \\
e_9^{a_1} &= 0.642864 , & e_9^{a_1} &= 2.947890 , \\
e_{10}^{a_1} &= 31.023038 , & e_{10}^{a_1} &= 1.829543 .
\end{align*}
\]

The coefficient \( a_2 \) is fitted similarly with the template:

\[
\begin{align*}
a_2 &= a_0^2 \cdot a_2^S , \\
a_0^2 &= c_0^2 \left[ 1 + c_0^{a_2} \nu + c_2^{a_2} \nu^3 \right] , \\
a_2^S &= \frac{1 + c_4^{a_2} S_\nu + c_5^{a_2} S_\nu^2 + c_6^{a_2} S_\nu^3 + c_7^{a_2} S_\nu^4}{1 + c_3^{a_2} S_\nu} , \\
e_i^{a_2} &= e_i^{a_2} \left[ 1 + c_2^{a_2} x_\nu \right], \quad \text{for } i = 4, \ldots, 9 .
\end{align*}
\]

The fitted \( a_0^S \) coefficients are:

\[
\begin{align*}
e_0^{a_2} &= 0.929192 , & e_1^{a_2} &= 1.334263 , \\
e_2^{a_2} &= -26.389790 , & e_3^{a_2} &= -1.289984 .
\end{align*}
\]

The coefficients of \( a_2^S \) are fitted in 2 steps as well. The coefficients \( e_i^{a_0} \) have been fitted to \( q = 4 \):

\[
\begin{align*}
e_4^{a_0} &= -0.886561 , & e_5^{a_0} &= -1.953955 , \\
e_6^{a_0} &= 1.366537 , & e_7^{a_0} &= 0.950212 , \\
e_8^{a_0} &= -2.531000 , & e_9^{a_0} &= 1.723991 .
\end{align*}
\]

The remaining coefficients model the extrapolation of the spin dependence to larger mass ratios and are:

\[
\begin{align*}
e_4^{a_1} &= 15.871482 , & e_5^{a_1} &= 5.066190 , \\
e_5^{a_1} &= 7.168498 , & e_6^{a_1} &= 6.709490 , \\
e_6^{a_1} &= 18.583382 , & e_7^{a_1} &= 5.764512 , \\
e_7^{a_1} &= -14.038654 , & e_8^{a_1} &= -17.12631 , \\
e_8^{a_1} &= 6.387917 , & e_9^{a_1} &= 3.438456 , \\
e_9^{a_1} &= 8.867098 , & e_{10}^{a_1} &= 2.910938 .
\end{align*}
