A Reduced Order Direct Coupling Coherent Quantum Observer for a Complex Quantum Plant

Ian R. Petersen and Elanor H. Huntington

Abstract—This paper extends previous results on constructing a direct coupling quantum observer for a quantum harmonic oscillator system. In this case, we consider a complex linear quantum system plant consisting of a network of quantum harmonic oscillators. Conditions are given for which there exists a direct coupling observer which estimates a collection of variables in the quantum plant. It is shown that the order of the observer can be the same as the number of variables to be estimated when this number is even and thus this is a reduced order observer.

I. INTRODUCTION

A number of papers have recently considered the problem of constructing a coherent quantum observer for a quantum system; e.g., see [1]–[4]. In the coherent quantum observer problem, a quantum plant is coupled to a quantum observer which is also a quantum system. The quantum observer is constructed to be a physically realizable quantum system so that the system variables of the quantum observer converge in some suitable sense to the system variables of the quantum plant. The papers [4]–[7] considered the problem of constructing a direct coupling quantum observer for a given closed quantum system. In [4], the proposed observer is shown to be able to estimate some but not all of the plant variables in a time averaged sense. Also, the paper [8] shows that a possible experimental implementation of the augmented quantum plant and quantum observer system considered in [4] may be constructed using a non-degenerate parametric amplifier (NDPA) which is coupled to a beamsplitter by suitable choice of the NDPA and beamsplitter parameters.

In the paper [4], the quantum plant consisted of a number of quantum harmonic oscillators where the number of variables to be estimated was allowed to be at most half of the total number of variables describing the quantum plant. However, the quantum plant was assumed to have very simple dynamics corresponding to a zero Hamiltonian. Then a quantum observer was constructed whose number of variables was equal to twice the number of variables to be estimated. In this paper we extend the results of [4] by first allowing for more general linear quantum plants with non-zero Hamiltonians. Conditions are given on whether a given set of variables of interest can be estimated via a direct coupling quantum observer. Then a direct coupling quantum observer is constructed whose order is the same as the number of variables to be estimated when this number is even. In the case that the number of variables to be estimated is odd, the order of the observer is one more than the number of variables to be estimated. Compared to the result in [4], this is a reduced order observer. As in [4], the convergence of the observer outputs to the plant outputs is a time averaged convergence since the overall plant-observer system is a closed quantum linear system.

II. QUANTUM SYSTEMS

In the quantum observer problem under consideration, both the quantum plant and the quantum observer are linear quantum systems; see also [9]–[11]. We will restrict attention to closed linear quantum systems which do not interact with an external environment. The quantum mechanical behavior of a linear quantum system is described in terms of the system observables which are self-adjoint operators on an underlying infinite dimensional complex Hilbert space $\mathcal{H}$. The commutator of two operators $x$ and $y$ on $\mathcal{H}$ is defined as $[x, y] = xy - yx$. Also, for a vector of operators $x$ on $\mathcal{H}$, the commutator of $x$ and a scalar operator $y$ on $\mathcal{H}$ is the operator $[x, y] = xy - yx$, and the commutator of $x$ and its adjoint $x^\dagger$ is the matrix of operators

$$[x, x^\dagger] \triangleq xx^\dagger - (x^\#x^T)^T,$$

where $x^\# \triangleq (x_1^* \ x_2^* \ \ldots \ x_n^*)^T$ and $^*$ denotes the operator adjoint.

The dynamics of the closed linear quantum systems under consideration are described by non-commutative differential equations of the form

$$\dot{x}(t) = Ax(t); \quad x(0) = x_0$$

where $A$ is a real matrix in $\mathbb{R}^{n \times n}$, and $x(t) = [x_1(t) \ldots x_n(t)]^T$ is a vector of system observables; e.g., see [9]. Here $n$ is assumed to be an even number and $\frac{n}{2}$ is the number of modes in the quantum system.

The initial system variables $x(0) = x_0$ are assumed to satisfy the commutation relations

$$[x_j(0), x_k(0)] = 2i\Theta_{jk}, \quad j, k = 1, \ldots, n,$$

where $\Theta$ is a real skew-symmetric matrix with components $\Theta_{jk}$. In the case of a single quantum harmonic oscillator, we can choose $x = (x_1, x_2)^T$ where $x_1 = q$ is the position operator, and $x_2 = p$ is the momentum operator. The
commutation relations are \([q, p] = 2i\). In general, the matrix \(\Theta\) is assumed to be of the form
\[
\Theta = \text{diag}(J, J, \ldots, J)
\]  
(3)
where \(J\) denotes the real skew-symmetric \(2 \times 2\) matrix
\[
J = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}.
\]

The system dynamics are determined by the system Hamiltonian which is a self-adjoint operator on the underlying Hilbert space \(\mathcal{H}\). For the linear quantum systems under consideration, the system Hamiltonian will be a quadratic form \(\mathcal{H} = \frac{1}{2} x^T R x\), where \(R\) is a real symmetric matrix. Then, the corresponding matrix \(A\) in (1) is given by
\[
A = 2\Theta R.
\]  
(4)
where \(\Theta\) is defined as in (3), e.g., see [9]. In this case, the system variables \(x(t)\) will satisfy the commutation relations at all times:
\[
[x(t), x(t)^T] = 2i\Theta \text{ for all } t \geq 0.
\]  
(5)
That is, the system will be physically realizable; e.g., see [9].

### III. ANALYSIS OF THE QUANTUM PLANT

In this section we will describe the class of quantum linear systems which will be considered as quantum plants. Also, we will analyse these quantum plants in order to provide conditions under which there exists a direct coupling observer which can estimate the quantum plant outputs.

We consider general closed linear quantum plants described by linear quantum system models of the following form:
\[
\begin{align*}
\dot{x}_p(t) &= A_p x_p(t) + B_p u(t); \quad x_p(0) = x_{0p}; \\
\dot{z}_p(t) &= C_p x_p(t)
\end{align*}
\]  
(6)
where \(z_p\) denotes the vector of system variables to be estimated by the observer and \(A_p \in \mathbb{R}^{n_p \times n_p}\), \(C_p \in \mathbb{R}^{m \times n_p}\). It is assumed that this quantum plant is physically realizable and corresponds to a plant Hamiltonian \(\mathcal{H}_p = \frac{1}{2} x^T R_p x_p\), where \(R_p\) is a symmetric matrix and \(A_p = 2\Theta_p R_p\). Here \(\Theta_p\) is of the form (3). Unlike the case in [4], we will not require that \(R_p\) is zero. However, we will assume that \(\det R_p = 0\) so that \(R_p\) has a non-trivial null space. In addition, we assume that the matrices \(R_p\) and \(C_p\) satisfy the following conditions:
\[
\begin{align*}
C_p (sI - \Theta_p)^{-1} R_p &\equiv 0; \\
C_p \Theta_p C_p^T &\equiv 0;
\end{align*}
\]  
(7)  
(8)
The matrix \(C_p\) is of rank \(m\).  
(9)
Note that if the matrix \(C_p\) is not full rank then some of the components of \(z_p\) can be expressed as linear combinations of the other components of \(C_p\). Hence, without loss of generality, we can eliminate these components of \(z_p\) to obtain a full rank \(C_p\).

In the sequel, we will show that these conditions imply that there exists a direct coupling quantum observer which can estimate the variables \(z_p\). However, we first analyse the quantum plant satisfying these conditions. Indeed, we first consider the controllability of the pair \((\Theta_p, R_p)\). Since \(\Theta_p^2 = -I\), it follows that the corresponding controllability matrix is given by
\[
\begin{bmatrix}
R_p & \Theta_p R_p & \Theta_p^2 R_p & \ldots & \Theta_p^{n_p-1} R_p \\
R_p & -R_p & -\Theta_p R_p & R_p & \ldots
\end{bmatrix};
\]
e.g., see [12]. This matrix has the same range space as the matrix
\[
\begin{bmatrix}
R_p & \Theta_p R_p \\
R_p & -R_p & -\Theta_p R_p & R_p & \ldots
\end{bmatrix}.
\]  
(10)
The range space of the matrix \(C_r\) will determine which variables of the quantum plant remain constant if the plant is not coupled to the quantum observer. These variables are those which can be estimated by the quantum observer. We can use the matrix \(C_r\) to transform the pair \((\Theta_p, R_p)\) into a form corresponding to controllable and uncontrollable subsystems; e.g., see [12]. Indeed, we construct an orthogonal matrix \(P\) using the svd of the matrix \(C_r\) as \(C_r = P S V^T\) where \(V\) is also an orthogonal matrix and \(S\) is a diagonal matrix. This construction of \(P\) yields
\[
P^T \Theta_p P = \begin{bmatrix}
\Theta_{11} & \Theta_{12} \\
0 & \Theta_{22}
\end{bmatrix}, \quad P^T R_p = \begin{bmatrix}
R_{p1} \\
0
\end{bmatrix};
\]
where the pair \((\Theta_{11}, R_{p1})\) is controllable. Here \(\Theta_{11} \in \mathbb{R}^{n_{p1} \times n_{p1}}\) and \(\Theta_{22} \in \mathbb{R}^{n_{p2} \times n_{p2}}\) such that \(n_{p1} + n_{p2} = n_p\).

We now use the fact that \(\Theta_p\) is a skew-symmetric matrix and hence \(P^T \Theta_p P\) is a skew-symmetric matrix. Therefore, we must have
\[
P^T \Theta_p P = \begin{bmatrix}
\Theta_{11} & 0 \\
0 & \Theta_{22}
\end{bmatrix}
\]  
(11)
where \(\Theta_{11}\) is skew-symmetric and \(\Theta_{22}\) is skew-symmetric. Also, since the matrix \(\Theta_{11}\) is non-singular, the matrices \(\Theta_{11}\) and \(\Theta_{22}\) must be non-singular.

We also use the fact that \(R_p\) is a symmetric matrix. To do this, we first write \(P = \begin{bmatrix}
P_{11} & P_{12} \\
P_{21} & P_{22}
\end{bmatrix}\) and
\[
P^T R_p = \begin{bmatrix}
R_{11} & R_{12} \\
0 & 0
\end{bmatrix}.
\]
Hence,
\[
P^T R_p P = \begin{bmatrix}
R_{11} & R_{12} \\
0 & 0
\end{bmatrix} \begin{bmatrix}
P_{11} & P_{12} \\
P_{21} & P_{22}
\end{bmatrix} = \begin{bmatrix}
R_{11} P_{11} + R_{12} P_{21} & R_{11} P_{12} + R_{12} P_{22} \\
0 & 0
\end{bmatrix}.
\]
However, \(R_p\) is symmetric and hence \(P^T R_p P\) is symmetric. Thus, the matrix \(P^T R_p P\) must be of the form
\[
P^T R_p P = \begin{bmatrix}
R_{p11} & 0 \\
0 & 0
\end{bmatrix},
\]  
(12)
where the matrix \(R_{p11}\) is symmetric. Also, since the pair \((\Theta_{11}, \begin{bmatrix}
R_{11} & 0
\end{bmatrix})\) is controllable, the condition (7) implies that the matrix \(C_p = C_p P\) must be of the form
\[
\begin{bmatrix}
0 & C_{p2}
\end{bmatrix}.
\]  
(13)
where the matrix \( \hat{C}_{p2} \in \mathbb{R}^{m \times n_{p2}} \) is of rank \( m \). From this, it follows that the condition \( 3 \) reduces to the condition

\[ \hat{C}_{p2} \Theta_{22} \hat{C}_{p2}^T = 0. \]  

(14)

Now since \( \Theta_{22} \) is nonsingular and \( \hat{C}_{p2} \) is of rank \( m \), it follows that the matrix \( \hat{C}_{p2} \Theta_{22} \) is of rank \( m \) and its null space is of dimension \( n_{p2} - m \). However, since \( \hat{C}_{p2} \) is of rank \( m \), the equation \( 14 \) implies we must have \( m \leq n_{p2} - m \) and hence we will require

\[ m \leq \frac{n_{p2} - \text{rank} \hat{C}_{p2}}{2} \]

in order for the conditions \( 7 \), \( 8 \), \( 9 \) to be satisfied.

We now introduce a change of variables

\[ \tilde{x}_p = P^T x_p = \begin{bmatrix} \tilde{x}_{p1} \\ \tilde{x}_{p2} \end{bmatrix} \]

to the system \( 9 \). It follows that

\[ \dot{\tilde{x}}_p = \begin{bmatrix} \dot{\tilde{x}}_{p1} \\ \dot{\tilde{x}}_{p2} \end{bmatrix} = P^T A_p P \tilde{x}_p = 2P^T \Theta_p P \tilde{x}_p = 2 \begin{bmatrix} \Theta_{11} & 0 \\ 0 & \Theta_{22} \end{bmatrix} \begin{bmatrix} R_{p11} & 0 \\ 0 & 0 \end{bmatrix} \tilde{x}_p = 2 \Theta_{11} R_{p11} \tilde{x}_{p1} \begin{bmatrix} 0 & 0 \\ 0 & \Theta_{22} \end{bmatrix} \begin{bmatrix} R_{p11} & 0 \\ 0 & 0 \end{bmatrix} \tilde{x}_p \]

(15)

Also,

\[ z_p = C_p P \tilde{x}_p = \begin{bmatrix} \begin{bmatrix} 0 & \hat{C}_{p2} \end{bmatrix} \tilde{x}_{p1} \end{bmatrix} = \hat{C}_{p2} \tilde{x}_{p2} \]

using \( 13 \).

It follows from \( 15 \) that the plant variables \( \tilde{x}_{p2} \) will remain constant while the variables \( \tilde{x}_{p1} \) evolve dynamically for the plant system. Also, we have shown that the variables \( z_p \) to be estimated must be chosen to depend only on the variables \( \tilde{x}_{p2} \) and not the variables \( \tilde{x}_{p1} \). This will mean that if the quantum plant is a closed quantum system and not coupled to the quantum observer, the variables \( z_p \) will remain constant. However, if the quantum plant is coupled to a quantum observer, this may longer apply. In the sequel, we will show that for a suitably designed quantum observer, the variables \( z_p \) will remain constant even when the quantum plant is coupled to the quantum observer.

IV. DIRECT COUPLING COHERENT QUANTUM OBSERVERS

We consider a reduced order direct coupled linear quantum observer defined by a symmetric matrix \( R_c \in \mathbb{R}^{n_a \times n_a} \), and matrices \( R_c \in \mathbb{R}^{n_p \times n_p} \), \( C_o \in \mathbb{R}^{m_p \times n_o} \). These matrices define an observer Hamiltonian

\[ \mathcal{H}_o = \frac{1}{2} x^T_o R_c x_o, \]

(16)

and a coupling Hamiltonian

\[ \mathcal{H}_c = \frac{1}{2} \hat{x}_{p1} R_c \hat{x}_{p1} + \frac{1}{2} \hat{x}_{p2}^T R_c \hat{x}_{p2} \]

(17)

The matrix \( C_o \) also defines the vector of output variables for the observer as \( z_o(t) = C_o x_o(t) \).

The augmented quantum linear system consisting of the quantum plant and the direct coupled quantum observer is then a quantum system of the form \( 1 \) described by the total Hamiltonian

\[ \mathcal{H}_a = \mathcal{H}_p + \mathcal{H}_c + \mathcal{H}_o \]

\[ = \frac{1}{2} x^T_o R_c x_o \]

(18)

where \( x_a = \begin{bmatrix} x_p \\ x_o \end{bmatrix} \) and \( R_a = \begin{bmatrix} R_p & R_c \\ R_c^T & R_o \end{bmatrix} \). Then, using \( 4 \), it follows that the augmented quantum linear system is described by the equations

\[ \begin{bmatrix} \dot{x}_p(t) \\ \dot{x}_o(t) \end{bmatrix} = A_a \begin{bmatrix} x_p(t) \\ x_o(t) \end{bmatrix}; \quad x_p(0) = x_{po}; \quad x_o(0) = x_{o0}; \]

\[ z_p(t) = C_p x_p(t); \]

\[ z_o(t) = C_o x_o(t) \]

(19)

where \( A_a = 2 \Theta_a R_a \). Here

\[ \Theta_a = \begin{bmatrix} \Theta_p & 0 \\ 0 & \Theta_o \end{bmatrix} \]

We now formally define the notion of a direct coupled linear quantum observer.

**Definition 1:** The matrices \( R_a \in \mathbb{R}^{n_a \times n_a} \), \( R_c \in \mathbb{R}^{n_p \times n_p} \), \( C_o \in \mathbb{R}^{m_p \times n_o} \) define a direct coupled linear quantum observer for the quantum plant \( 4 \) if the corresponding augmented linear quantum system \( 19 \) is such that

\[ \lim_{T \to \infty} \frac{1}{T} \int_0^T (z_p(t) - z_o(t)) dt = 0. \]

(20)

V. CONSTRUCTING A REDUCED ORDER DIRECT COUPLING COHERENT QUANTUM OBSERVER

In order to construct a reduced order direct coupled coherent observer, we assume that the quantum plant satisfies the conditions \( 7 \), \( 8 \) and \( 9 \) and apply the transformation

\[ \begin{bmatrix} \tilde{x}_{p1} \\ \tilde{x}_{p2} \end{bmatrix} = \tilde{x}_p = P^T x_p \]

considered in the previous section. Also, we assume that the coupling Hamiltonian \( \mathcal{H}_c \) depends only on \( \tilde{x}_{p2} \) and \( x_o \) but not on \( \tilde{x}_{p1} \); i.e., we can write

\[ \mathcal{H}_c = \frac{1}{2} \tilde{x}_{p2}^T R_c x_o + \frac{1}{2} \tilde{x}_{p2}^T R_c \tilde{x}_{p2} \]

(21)

where

\[ R_c = P \begin{bmatrix} 0 \\ \tilde{R}_c \end{bmatrix} \]

(22)

Hence, we can write

\[ \mathcal{H}_a = \frac{1}{2} \tilde{x}_{p1}^T R_{p11} \tilde{x}_{p1} + \frac{1}{2} \tilde{x}_{p2}^T \tilde{R}_c x_o + \frac{1}{2} \tilde{x}_{p2}^T \tilde{R}_c \tilde{x}_{p2} + \frac{1}{2} \tilde{x}_{p2}^T R_{o0} x_o \]

\[ = \frac{1}{2} \tilde{x}_{p1}^T \tilde{R}_a \tilde{x}_{p1} \]

where \( x_a = \begin{bmatrix} \tilde{x}_{p1} \\ \tilde{x}_{p2} \end{bmatrix} \) and \( R_a = \begin{bmatrix} R_{p11} & 0 & 0 \\ 0 & 0 & \tilde{R}_c \\ 0 & \tilde{R}_c & R_o \end{bmatrix} \).
We now suppose that
\[ n_o = \begin{cases} 
  m & \text{if } m \text{ is even;} \\
  m + 1 & \text{if } m \text{ is odd.}
\end{cases} \]
Thus, \( n_o \) is an even number and this corresponds to a reduced
order quantum observer.

We also suppose that the matrices \( R_o, \tilde{R}_o, C_o \) are such that
\[
\tilde{R}_o = \alpha \beta T, \quad \alpha = \tilde{C}^{T}_{p2}, \quad R_o > 0
\]  
(23)
where \( \tilde{C}^{T}_{p2} \in \mathbb{R}^{n_o \times m} \) and \( \beta \in \mathbb{R}^{n_o \times m} \) is full rank. In
addition, we write \( \Theta = \begin{bmatrix} \Theta_{11} & 0 & 0 \\
0 & \Theta_{22} & 0 \\
0 & 0 & \Theta_o \end{bmatrix} \) where \( \Theta_{11}, \Theta_{22} \)
are defined as in [1] and \( \Theta_o \in \mathbb{R}^{n_o \times n_o} \) is of the form
[3]. Hence, the augmented system equations [19] describing the
combined plant-observer system imply
\[
\begin{align*}
\dot{x}_p(t) &= 2\tilde{C}^{T}_{p2}\Theta_{22}\alpha T x_o(t); \\
\dot{x}_o(t) &= 2\Theta_o\alpha T \tilde{x}_p(t) + 2\Theta_o R_o x_o(t); \\
z_p(t) &= \tilde{C}^{T}_{p2} x_p(t); \\
z_o(t) &= C_o x_o(t).
\end{align*}
\]  
(24)

We will show that the given assumptions imply that the quantity \( z_p(t) = \tilde{C}^{T}_{p2} x_p(t) \) will be constant for the
augmented quantum system (24). Indeed, it follows from (24)
that
\[
\dot{z}_p(t) = 2\tilde{C}^{T}_{p2}\Theta_{22}\alpha T x_o(t) = 2\tilde{C}^{T}_{p2}\Theta_{22}\tilde{C}^{T}_{p2}\beta T x_o(t) = 0
\]  
using (14). Therefore,
\[
z_p(t) = z_p(0) = z_p
\]  
(25)
for all \( t \geq 0. \)

It now follows from (24) that
\[
\dot{x}_o(t) = 2\Theta_o\beta \tilde{C}^{T}_{p2} \tilde{x}_p(t) + 2\Theta_o R_o x_o(t) \\
= 2\Theta_o R_o x_o(t) + 2\Theta_o \beta z_p.
\]  
(26)
From this equation, we define the “steady state” value of the
vector \( x_o \) as
\[
x_o = -R_o^{-1} \beta z_p.
\]
Then we define the “error vector”
\[
\tilde{x}_o(t) = x_o(t) - x_o.
\]
It follows from (26) that \( \tilde{x}_o(t) \) satisfies the differential
equation
\[
\begin{align*}
\dot{\tilde{x}}_o(t) &= 2\Theta_o R_o \tilde{x}_o(t) + 2\Theta_o \beta z_p \\
&= 2\Theta_o R_o \tilde{x}_o(t) + 2\Theta_o R_o x_o + 2\Theta_o \beta z_p \\
&= 2\Theta_o R_o \tilde{x}_o(t).
\end{align*}
\]
We now show that
\[
\lim_{T \to \infty} \frac{1}{T} \int_0^T \tilde{x}_o(t) dt = 0
\]  
(27)
following the proof of a similar fact in [6]. First note that
the quantity \( \tilde{H}_o(t) = \frac{1}{2} \tilde{x}_o(t)^{T} R_o \tilde{x}_o(t) \) remains constant in
time. Indeed,
\[
\frac{d}{dt} \tilde{H}_o(t) = \frac{1}{2} \tilde{x}_o(t)^{T} R_o \dot{\tilde{x}}_o(t) + \frac{1}{2} \dot{\tilde{x}}_o(t)^{T} R_o \tilde{x}_o(t) \\
= -\tilde{x}_o(t)^{T} R_o \Theta_o R_o \tilde{x}_o(t) + \dot{\tilde{x}}_o(t)^{T} R_o \Theta_o R_o \tilde{x}_o(t) = 0
\]
since \( R_o \) is symmetric and \( \Theta_o \) is skew-symmetric. That is
\[
\frac{1}{2} \tilde{x}_o(t)^{T} R_o \tilde{x}_o(t) = \frac{1}{2} \tilde{x}_o(0)^{T} R_o \tilde{x}_o(0) \quad \forall t \geq 0.
\]  
(28)
However, \( \tilde{x}_o(t) = e^{2\Theta_o R_o t} \tilde{x}_o(0) \) and \( R_o > 0 \). Therefore, it follows from (28) that
\[
\sqrt{\lambda_{\text{max}}(R_o)} \| e^{2\Theta_o R_o t} \tilde{x}_o(0) \| \leq \sqrt{\lambda_{\text{min}}(R_o)} \| \tilde{x}_o(0) \|
\]
for all \( \tilde{x}_o(0) \) and \( t \geq 0. \). Hence,
\[
\| e^{2\Theta_o R_o t} \| \leq \sqrt{\frac{\lambda_{\text{max}}(R_o)}{\lambda_{\text{min}}(R_o)}}
\]  
(29)
for all \( t \geq 0. \)

Now since \( \Theta_o \) and \( R_o \) are non-singular,
\[
\int_0^T e^{2\Theta_o R_o t} dt = \frac{1}{2} e^{2\Theta_o R_o t} R_o^{-1} \Theta_o^{-1} - \frac{1}{2} R_o^{-1} \Theta_o^{-1}
\]
and therefore, it follows from (29) that
\[
\frac{1}{T} \int_0^T e^{2\Theta_o R_o t} dt \\
\leq \frac{1}{2T} \left( e^{2\Theta_o R_o t} R_o^{-1} \Theta_o^{-1} \right) - \frac{1}{2T} R_o^{-1} \Theta_o^{-1} \\
\leq \frac{1}{2T} \left( \sqrt{\lambda_{\text{max}}(R_o)} \| R_o^{-1} \Theta_o^{-1} \| \right) \\
\leq 0
\]
as \( T \to \infty. \) Hence,
\[
\lim_{T \to \infty} \frac{1}{T} \int_0^T \tilde{x}_o(t) dt \\
= \lim_{T \to \infty} \frac{1}{T} \int_0^T e^{2\Theta_o R_o t} \tilde{x}_o(0) dt \\
\leq \lim_{T \to \infty} \frac{1}{T} \int_0^T e^{2\Theta_o R_o t} dt \| \tilde{x}_o(0) \| \\
= 0.
\]
This implies
\[
\lim_{T \to \infty} \frac{1}{T} \int_0^T \tilde{x}_o(t) dt = 0.
\]
Now we have
\[
\lim_{T \to \infty} \frac{1}{T} \int_0^T z_o(t) dt = \lim_{T \to \infty} \frac{1}{T} \int_0^T C_o x_o(t) dt \\
= \lim_{T \to \infty} \frac{1}{T} \int_0^T C_o (\tilde{x}_o(t) + \tilde{z}_o) dt \\
= \lim_{T \to \infty} \frac{1}{T} \int_0^T C_o \tilde{x}_o dt \\
= C_o \tilde{x}_o = -C_o R_o^{-1} \beta z_p.
\]

We now choose the matrices \( C_o \in \mathbb{R}^{m \times n_o} \) and \( \beta \in \mathbb{R}^{n_o \times m} \) so that
\[
-C_o R_o^{-1} \beta = I. \tag{30}
\]
This is always possible since \( n_o \geq m \). It follows that
\[
\lim_{T \to \infty} \frac{1}{T} \int_0^T z_o(t) dt = z_p
\]
and hence, the condition (20) is satisfied. Thus, we have proved the following theorem.

**Theorem 1:** Consider a quantum plant of the form \( (6) \) satisfying the conditions (7), (8), (9). Then the matrices \( R_o, \tilde{R}_c, C_o \) constructed as in (23), (30) will define a reduced order direct coupled quantum observer achieving time-averaged consensus convergence for this quantum plant.

VI. ILLUSTRATIVE EXAMPLE

We now present some numerical simulations to illustrate the reduced order direct coupled quantum observer described in the previous section. We choose the quantum plant to have
\[
R_p = \begin{bmatrix}
1 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1
\end{bmatrix}.
\]

Then, the corresponding matrix \( C_r \) defined in (19) is given by
\[
c_r = \begin{bmatrix}
1 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1
\end{bmatrix}
\]
This matrix has rank 2. From this, the orthogonal matrix \( P \) is calculated by finding the svd of \( C_r \). This yields
\[
P = \begin{bmatrix}
-0.5774 & 0.0000 & 0.5825 & -0.5722 & -0.0000 & -0.0000 \\
0 & -0.5774 & 0.5825 & -0.5722 & -0.0000 & 0.0000 \\
-0.5774 & -0.0000 & -0.2912 & 0.2861 & 0.6038 & -0.1365 \\
0 & -0.5774 & -0.2912 & 0.2861 & -0.1365 & -0.6038 \\
-0.5774 & -0.0000 & -0.2912 & 0.2861 & 0.6038 & -0.1365 \\
0 & -0.5774 & -0.2912 & 0.2861 & -0.1365 & 0.6038
\end{bmatrix}
\]
The corresponding transformed plant Hamiltonian matrix \( \tilde{R}_p = P^T R_p P \) is in the form (12) where
\[
R_{p11} = \begin{bmatrix}
3 & 3 \\
3 & 3
\end{bmatrix}.
\]
Also, the transformed commutation matrix \( \tilde{\Theta}_p = P^T \Theta_p P \) is in the form (11) where
\[
\Theta_{11} = \begin{bmatrix}
0 & 1 \\
-1 & 0
\end{bmatrix}, \quad \Theta_{22} = \begin{bmatrix}
0 & 1 & 0 & 0 \\
-1 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 \\
0 & 0 & 1 & 0
\end{bmatrix}.
\]

In order to choose a suitable value of the matrix \( C_p \), so that condition (7) is satisfied, we choose \( \tilde{C}_p = C_p P \) of the form (13) where \( \tilde{C}_{p2} \in \mathbb{R}^{2 \times 4} \). Also, we require that the condition (14) is satisfied. It is straightforward to verify that this condition is satisfied by the matrix
\[
\tilde{C}_{p2} = \begin{bmatrix}
1 & 1 & 1 & 1 \\
1 & 1 & -1 & -1
\end{bmatrix}.
\]
This corresponds to the matrix
\[
C_p = \begin{bmatrix}
0.0103 & 1.1547 & 0.5522 & -1.4076 \\
0.0103 & -1.1547 & -0.5522 & 1.4076 \\
0.5625 & 0.5625 & 1.4076 & -1.4076 \\
-0.5625 & -0.5625 & -1.4076 & 1.4076
\end{bmatrix},
\]
which is such that conditions (7), (8), (9) are satisfied.

The quantum plant defined by the matrices \( R_p \) and \( C_p \) given above is a plant of the form considered in Section III where \( n_p = 6, n_{p1} = 2, n_{p2} = 4, \) and \( m = 2 \). Hence, we will construct a reduced order observer as described in Section V with \( n_o = 2 \). In order to construct the observer, we need to choose matrices \( R_o > 0, \beta \) and \( C_o \) such that (30) is satisfied. In this example, we will choose
\[
R_o = I, \quad C_o = I, \quad \beta = -I.
\]
Then the matrix \( \tilde{R}_c \) is constructed according to (23) as
\[
\tilde{R}_c = \begin{bmatrix}
-1 & -1 \\
-1 & -1
\end{bmatrix}.
\]
From this, the matrix \( R_c \) is constructed according to (22) as
\[
R_c = \begin{bmatrix}
-0.0103 & -0.0103 \\
-1.1547 & -1.1547 \\
-0.5522 & 0.5625 \\
1.4076 & -0.2530 \\
0.5625 & -0.5522 \\
-0.2530 & 1.4076
\end{bmatrix}.
\]
The augmented plant-observer system described by the equations (19). To simulate these equations, we can write
\[
x_a(t) = \Phi(t)x_o(0)
\]
where \( \Phi(t) = e^{2\Theta_o R_o t} \). Furthermore, the plant variables to be estimated are given by
\[
z_p(t) = \begin{bmatrix}
C_p & 0
\end{bmatrix} \Phi(t)x_o(0)
\]
and the observer output variables are given by
\[
z_o(t) = \begin{bmatrix}
0 & C_o
\end{bmatrix} \Phi(t)x_o(0).
\]
Although the quantities \( z_p(t) \) and \( z_o(t) \) are operators which cannot be plotted directly, we can plot the coefficients in the above equations which define the components of \( z_p(t) \) or \( z_o(t) \) with respect to the initial condition operators in \( x_o(0) \).
In Figure 1, we plot these coefficients corresponding to the first plant variable to be estimated. In Figure 2, we plot these coefficients corresponding to the second plant variable to be estimated. These figures verify that the quantity \( z_p(t) \) remains constant at its initial value.
In Figure 3, we plot these coefficients corresponding to the first observer output variable, which is designed to provide an
estimate of the first plant variable to be estimated. In Figure 4 we plot these coefficients corresponding to the second observer output variable, which is designed to provide an estimate of the second plant variable to be estimated. From Figures 3 and 4 we can see that \( z_p(t) \) evolves in a time-varying and oscillatory way.

To illustrate the time average convergence property of the quantum observer (20), we now plot the time averaged quantities corresponding to Figures 3 and 4. In Figure 5 we plot the time averaged coefficients corresponding to the first observer output variable. Comparing this figure with Figure 1, we can see that the time average of the first component of \( z_o(t) \) converges to the first component of \( z_p \).

In Figure 6 we plot the time averaged coefficients corresponding to the second observer output variable. Comparing this figure with Figure 2 we can see that the time average of the second component of \( z_o(t) \) converges to the second component of \( z_p \).
