Outbreak.info Research Library: a standardized, searchable platform to discover and explore COVID-19 resources

Ginger Tsueng, Julia L. Mullen, Manar Alkuzweny, Marco Cano, Benjamin Rush, Emily Haag, Jason Lin, Dylan J. Welzel, Xinghua Zhou, Zhongchao Qian, Alaa Abdel Latif, Emory Hufbauer, Mark Zeller, Kristian G. Andersen, Chunlei Wu, Andrew I. Su, Karthik Gangavarapu & Laura D. Hughes

Outbreak.info Research Library is a standardized, searchable interface of coronavirus disease 2019 (COVID-19) and severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) publications, clinical trials, datasets, protocols and other resources, built with a reusable framework. We developed a rigorous schema to enforce consistency across different sources and resource types and linked related resources. Researchers can quickly search the latest research across data repositories, regardless of resource type or repository location, via a search interface, public application programming interface (API) and R package.

In January 2020, SARS-CoV-2 was identified as the virus responsible for a series of pneumonia cases with unknown origin. As the virus spread globally, the scientific community rapidly released research outputs (such as publications, clinical trials and datasets) and resources (websites, portals and more). The frequently uncoordinated generation and curation of resources exacerbated four challenges in finding and using them: volume, fragmentation, variety and standardization (Supplementary Fig. 1). While many specialized websites were developed independently, a centralized and standardized repository for finding COVID-19 research has limited researchers’ ability to discover these resources and translate them into insights about the virus.

To address the fragmented research landscape, individual and community efforts created shared Google spreadsheets to aid in discoverability, but these efforts were not scalable and often lacked metadata to promote findability (aside from Navarro and Capdarest-Arest). Several projects attempted to address the volume and fragmentation issues through large-scale aggregation but failed to tackle variety, focusing on a single resource type such as publications. Even within a particular type of resource, standardization issues abound. Repositories pivoted quickly to curate COVID-19 content from their collections using pre-existing metadata standards but were often not interoperable with other sources. For example, PubMed created LitCovid based on their MEDLINE standards, and the National Clinical Trials Registry cataloged COVID-19 clinical trials using their schema, but the World Health Organization (WHO) International Clinical Trials Registry uses different conventions. Similarly, Zenodo and Figshare do not agree on the marginality, cardinality and property names, despite compatibility with the standards of https://schema.org.

We address issues in metadata volume, variety, standardization and fragmentation by creating a single searchable index of COVID-19 publications, clinical trials, datasets and more: the outbreak.info Research Library. To address variety and standardization, we developed a harmonized schema based on https://schema.org, a framework standardizing metadata across the internet. Using this schema, we harvested and harmonized metadata from 16 resources (Fig. 1a). Daily

LitCovid is the dominant source. To ensure ease of use of our Research Library, we conducted usability studies and iteratively improved our site (Supplementary Fig. 2).

To further address fragmentation and maintenance issues, we use modular infrastructure, allowing easy addition of new data sources, including community contributions. Citizen scientists have played an active role in data collection19 (https://covidsample.org/) and accessibility12,20 throughout the pandemic. Given the highly fragmented, diffuse and frequently changing nature inherent to biomedical research, we built in three mechanisms to expand the Research Library through community participation (Supplementary Fig. 3a).

First, contributors can submit individual or multiple datasets via an online form that ensures that the curated metadata conform to our schema. Second, leveraging the benefits of human curation, the community-contributed metadata using the form can be updates ensure that site users have up-to-date information, essential amid a constantly changing research landscape.

Next, to address volume and fragmentation, we developed a web-based search portal for researchers to browse across the centralized and standardized resources (https://outbreak.info/resources) and an API to access and analyze information en masse (https://api.outbreak.info). Within the search interface, users can search, filter and view related records and share the associated metadata to easily query across resource repositories and types. For instance, a single query (for example, ‘Delta variant’) to our API can return relevant publications, datasets, clinical trials and more (Fig. 1b), and the Research Library summarizes the search results in visualizations to promote exploration. For instance, the histogram in Fig. 1b indicates that the number of resources mentioning ‘Delta variant’ began growing in mid 2021 and declined in the summer of 2022, and the donut charts show that...
To support resource exploration and interpretation, we added properties (value-added metadata) to every class in our schema that would support searching, filtering and browsing (topicCategories, Supplementary Fig. 5a); linkage and exploration (correction, citedBy, isBasedOn, isRelatedTo; Supplementary Fig. 5b); and interpretation (qualitative evaluations) of resources. We selected these properties based on pre-existing citizen science- and resource-curation activities, suggesting their value in promoting discoverability. For example, citizen scientists categorized resources in their lists or collections by type (Dataset, ClinicalTrials, etc.) in their outputs as area of research (epidemiological, prevention, etc.) as they found these classifications helpful for searching, filtering and browsing their lists or collections. Given the ability of citizen scientists to perform information extraction and their immense contributions to classification tasks, we incorporated citizen science contributions into the training data for classifying resources into topic categories. Citizen scientists also provided Oxford 2011 Levels of Evidence annotations to improve its interpretability (that is, understanding the credibility or quality of the resource). To further enable assessment of the quality of a resource, we leveraged Digital Science’s Altmetric ratings.

Finally, we integrated resources with the analyses that we developed to track SARS-CoV-2 variants of concern (VOCs), sets of mutations within the virus associated with increased transmissibility, virulence and/or immune evasion. Researchers can seamlessly traverse from a specific variant report such as Omicron to resources in the Research Library that help understand its behavior (Supplementary Fig. 5c), and variant searches are among our most commonly queried terms (Supplementary Table 1a). Without a centralized search interface with linked records such as outbreak.info, a similar attempt to explore resources would require extensive manual searching from multiple different sites (Supplementary Fig. 6), each with their own interfaces and corresponding search capabilities.

To demonstrate the unique features of the outbreak.info Research Library, we explored the dynamics of research into SARS-CoV-2 variants over time to address two key questions: (1) how has the research community responded to the emergence of new variants and (2) how has that response changed over time? We extracted research related to variants in the Research Library using the query ‘variant OR lineage’, allowing us to query metadata from 16 sources of different research types simultaneously (Fig. 2a). Over 10,000 separate entries about variants are within the Library as of October 2022, including publications, datasets, clinical trials, protocols and more. Using filters and the quality metrics provided through

**Fig. 2 | Resources concerning variants within the outbreak.info Research Library.**

- **b.** A variant protocol discovered within the Library.
- **c.** As VOCs were designated, the proportion of research in the Library focused on variants increased.
- **d.** The increase in research on each VOC mirrored its worldwide prevalence, with research on the transmissibility, virulence and/or immune evasion supporting their VOC designation by public health agencies, and these designations encouraging further research.

...
Altmetric badges, we quickly identified which results have been recognized by the community via Altmetric scores, such as a quantitative PCR protocol with reverse transcription (RT–qPCR) to screen VOCs (Fig. 2b). Clearly, variants are an active area of research, but has this enthusiasm changed over time? Using the outbreak.info R package, we accessed the harmonized metadata to examine the proportion of research related to variants in the Research Library over time. We observed an increase in research on variants following the first identification of VOCs such as Alpha (B.1.1.7) and Beta (B.1.351) (Fig. 2c). This increase was even more prominent for the Omicron (B.1.1.529) variant in late 2021; we hypothesize that this increase was due to the heightened awareness of the value in studying variants among the scientific community, and early indications that the variant could be of global concern (high growth rate of Omicron and the presence of many mutations in important sites). To examine how research differed by VOC over time, we constructed queries for each VOC, including its Pango lineage name and associated sublineages. With the three VOCs that became the dominant worldwide form of SARS-CoV-2 (Alpha, Delta and Omicron), we find that the increase in research on these VOCs mirrors the rise in worldwide prevalence for each variant, with the research output roughly proportional to global prevalence (Fig. 2d). With Alpha and Delta, there was a slight lag in research publications with Alpha and Delta, there was a slight lag in research publications. While there was no reported with Omicron, and research on Omicron over the last 10 months has dwarfed that for the other VOCs. Lastly, research on previously circulating variants (Alpha, Beta, Gamma, Delta) continues, even though these variants are rarely detected presently, and focuses on retrospective analyses, fundamental studies on mechanisms of action, Omicron comparisons and studies of recombinant variants. In sum, the research community’s response to the emergence of new variants has been robust, has become a greater focus of overall research effort over the last year and quickly pivots to studying the dominant variant.

The outbreak.info Research Library and resources API have been widely used by the external community, including journalists, members of the medical and public health communities, students and biomedical researchers. For instance, the RADx-Rad Data Coordination Center created the SearchOutbreak app (https://searchoutbreak.netlify.app), which uses the OpenAPI to collect articles for customized research digests for its partners. On average, the Research Library receives nearly 3,000 pageviews per month, of which 85% are unique visitors (Supplementary Table 1b). The Research Library site has been used for nearly 6,300 unique hits per month (including web traffic and data from distributed data sources into a searchable platform. Our metadata-processing platform is modular, allowing easy extension to add new metadata sources including contributions from the community, allowing the Research Library to grow with the pandemic as research changes. To enable further analysis, we enable programmatic access to the standardized library. Lastly, with the embrace of open science stored in decentralized sources, quickly finding information will be critical for the next pandemic. Our approach to unify metadata across repositories will serve as a template for rapidly creating a unified search interface to aggregate research outputs for any pathogen or any research domain.

Schema development

The development of the schema for standardizing our collection of resources is as previously described27. Briefly, we prioritized six classes of resources that had seen a rapid expansion at the start of the pandemic due to their importance to the research community: publications, datasets, clinical trials, analyses, protocols and computational tools. We identified the most closely related classes from https://schema. org and mapped their properties to available metadata from two to five of the most prolific sources. Additionally, we identified subclasses that were needed to support the aforementioned six classes and standardized the properties within each class. In addition to standardizing ready-to-harvest metadata, we created new properties that would support the linkage, exploration and evaluation of our resources. Our schema was then refined as we iterated through the available metadata when assembling COVID-19 resources. For example, publication providers such as PubMed typically use the 'author' property in their metadata, while dataset providers such as Figshare and Zenodo are compliant with the DataCite schema and typically prefer 'creator'. Although both properties are valid for their respective https://schema.org classes, we normalized our schema to use 'author' for all six of our classes (Dataset, ClinicalTrial, Analysis, Protocol, Publication, ComputationalTool), because we expected the volume of publications to dwarf that of all other classes of resources. We added this schema to the Schema Registry of the Data Discovery Engine (DDE)27, a project to share and reuse schemas and register datasets according to a particular schema. The Outbreak schema is available at https://discovery.biothings.io/view/outbreak.

Assembly of COVID-19 resources

The resource metadata pipeline for outbreak.info includes two ways to ingest metadata (Supplementary Fig. 7). First, metadata can be ingested from other resource repositories or collections using the BioThings SDK28 data plugins. By leveraging the BioThings SDK, we developed a technology stack that addresses the fragmentation issue by easily integrating metadata from different pre-existing resources. For each resource repository or collection, a parser or data plugin enables automated import and updates from that resource. To import the data, the metadata is harvested from the source using API calls (if available), HTML web scraping or .CSV or .TXT tables of metadata. All structured metadata provided by the sources is compiled and mapped to our schema using custom Python scripts. The harmonized metadata is dumped into a JSON output. Supplementary Fig. 8 shows the completeness of each metadata property within our schema, broken down by resource type (data are provided in Supplementary Table 2). Data plugin code for the sources is available at https://github.com/outbreak-info (Code availability).

In the second mechanism, metadata for individually curated resources can be submitted via an online form through the DDE Meta-data Registry29. To assemble the outbreak.info collection of resources, we collected a list of over a hundred separate resources on COVID-19 and SARS-CoV-2. This list (Supplementary Table 3) included generalist open data repositories, biomedical-specific data projects including those related to COVID-19, and large repositories. As it is not feasible for one team to locate, identify and collect standardized metadata from these individual datasets and research outputs, we leveraged the DDE27 to enable crowdsourcing and citizen science participation in the curation of individual resource metadata.

A Tornado server is used to create an API endpoint, api.outbreak.info/resources, that leverages the search capabilities of Elasticsearch to efficiently query data. Within the search results, Elasticsearch sorts them by relevance based on Lucene’s Practical Scoring Function10, which prioritizes the query normalization factor, coordination factor, term frequency, inverse document frequency and any custom query-boosting fields selected by the user33. To adjust this behavior based on common search patterns, we upweighted queries for which the search term occurs in the name field and/or the name of a clinical trial therapeutic intervention (for example, ‘remdesivir’ with the following parameters: weight of 4 for ‘name’ and 3 for ‘interventions.name’). We continue to monitor common query patterns using our analytics to refine the scoring algorithm to improve the list of results for the user. Within the web interface, the user has the option to sort by the best match-relevance score, update date for the document or alphabetically by name. Within search queries, terms are automatically combined by ‘AND’. For instance, the search ‘long COVID’ will be interpreted as ‘long AND COVID’. This search will find resources containing both terms, although not necessarily together; the Elasticsearch default scoring function will first list resources that contain both words together and that frequently mention the terms. Exact phrases can be explicitly declared by encapsulating the terms in quotes (for example, ‘long COVID’ to search only for the phrase ‘long COVID’). Additionally, terms can be combined by the term ‘OR’ (for example, (Moderna OR Pfizer) AND (side effects’ OR ‘adverse effects’)). Further details on advanced searching behavior are provided in our guide to the outbreak.info R package at https://outbreak-info.github.io/R-outbreak-info/articles/researchlibrary.html#some-notes-on-constructing-queries. Further optimization will be the subject of future work, based on continuing analysis of analytic patterns for the most common search queries and filters to promote user-driven design. Additional work will also focus on creating an advanced query builder to make it easier to combine terms by any combination of ‘AND’, ‘OR’ and ‘NOT’ and to help the user search for exact phrases.

To update the API with new data provided by the data sources, the BioThings Hub schedules daily updates to pull data upstream and add them to the existing index. The BioThings Hub independently maintains each data source, enabling independence if an individual data source pipeline breaks, and maintains historical data by default, creating automated backups. The code for the server-side application is available at https://github.com/outbreak-info/outbreak.api (https://doi.org/10.5281/zenodo.7343503).

Creation of the Research Library API and query interface

To accommodate a large number of heterogeneous data sources, each of which is independently harvested, we used the BioThings SDK framework to combine the data sources into a combined, public searchable index (Supplementary Fig. 7). The JSON outputs of our data plugins are ingested by the BioThings framework and merged into an intermediary MongoDB database, and the processed data are indexed in an Elasticsearch index that can be accessed through our public API (api.outbreak.info). The BioThings SDK plugin architecture handles errors in individual parsers without affecting the availability of the API itself. Errors thrown by individual parsers may result in a lack of updates of an individual resource until the error is resolved, but the API will serve the latest version of data from the broken parser and up-to-date data from all functional parsers, which will continue to be updated independently. Using the plugin architecture also allows the creation and maintenance of Individual resource parsers to be crowdsourced to anyone with basic Python knowledge and a GitHub account. Although resource plugins allow outbreak.info to ingest large amounts of standardized metadata, there are still many individual datasets and research outputs scattered throughout the web that are not located in large repositories. As it is not feasible for one team to locate, identify and collect standardized metadata from these individual datasets and research outputs, we leveraged the DDE27 to enable crowdsourcing and citizen science participation in the curation of individual resource metadata.

Nature Methods
Outbreak.info Research Library web application and metadata access
The web application was built using Vue.js, a model–view–viewmodel JavaScript framework that enables the two-way binding of user interface elements and the underlying data allowing the user interface to reflect any changes in underlying data and vice versa. The client-side application uses the high-performance API to interactively perform operations on the database. To iteratively improve the interface, we conducted usability studies as described in Supplementary Fig. 2. The code for the client-side application is available at https://github.com/outbreak-info/outbreak.info (https://doi.org/10.5281/zenodo.7343497). To enable programmatic access to all our harmonized metadata collection, all data are available in our API (api.outbreak.info) and can be accessed through an R package as described by Ganganarapu et al. 28 (package website, https://outbreak-info.github.io/R-outbreak-info/; code, https://github.com/outbreak-info/R-outbreak-info, https://doi.org/10.5281/zenodo.7343501).

Community curation of resource metadata
Resource plugins such as those used in the assembly of COVID-19 resources do not necessarily have to be built by our own team. We used the BioThings SDK28 and the DDE27 so that individual resource collections can be added by writing BioThings plugins that conform to our schema. Expanding available classes of resources can be easily carried out by extending other classes from https://schema.org via the DDE Schema Playground at https://discovery.biothings.io/schema-playground. Community contributions of resource plugins can be carried out via GitHub. In addition to contributing resource plugins for collections or repositories of metadata, users can enter metadata for individual resources via the automatic guides created by the DDE. To investigate potential areas of community contribution, we asked two volunteers to inspect 30 individual datasets sprinkled around the web and collect the metadata for these datasets. We compared the results between the two volunteers, and their combined results were subsequently submitted into the collection via the DDE’s Outbreak Data Portal Guide at https://discovery.biothings.io/guide/outbreak/dataset. Although limited by the original submission form (Google forms), the raw and merged responses illustrating the thoroughness of the submissions from the two volunteers can be found at https://docs.google.com/sheets/d/1qc40UF1oyXedfL2L1zRoXVi3BWBHtU46c0cMYs/edit?usp=sharing. Although both of our volunteers provided values for many of the available metadata properties (name, description, topicCategories, keywords, etc.), one provided an extensive list of authors. Using the BioThings SDK in conjunction with the DDE allows us to centralize and leverage individualized curation efforts that often occur at the start of a pandemic. Improvements or updates for manually curated metadata can be submitted via GitHub pull requests.

Community curation of searching, linkage and evaluation metadata and scaling with machine learning
In an effort to enable improved searching and filtering, we developed a nested list of thematic or topic-based categories based on an initial list developed by LitCovid40 with input from the infectious disease research community and volunteer curators. The list consists of 11 broad categories and 24 specific child categories. LitCovid organized publications into eight research areas such as treatments or prevention, but these classifications are not available in the actual metadata records for each publication. To obtain these classifications from LitCovid, subsets of exports of identifiers were downloaded from LitCovid and then mapped to the metadata records from PubMed.

Whenever possible, sources with thematic categories were mapped to our list of categories to develop a training set for basic binary (in-group–out-group) classifications of required metadata fields such as (title, abstract and/or description). If an already curated training set could not be found for a broad category, it would be created using an iterative process involving term–phrase searching on LitCovid, evaluating the specificity of the results, identifying new search terms by keyword frequency and repeating the process. To generate training data for classifying resources into specific topic categories, the results from several approaches were combined. These approaches include direct mapping from LitCovid research areas, keyword mapping from LitCovid, logical mapping from NCT ClinicalTrials metadata, the aforementioned term search iteration and citizen science curation of Zenodo and Figshare datasets. Details on the logical mapping from NCT ClinicalTrials metadata can be found at https://github.com/ghtsueg/outbreak_CT_classifier (https://doi.org/10.5281/zenodo.7442988). The keyword mapping from LitCovid can be found at https://github.com/outbreak-info/topic_classifier/tree/main/data/keyword and https://github.com/outbreak-info/topic_classifier/tree/main/data/subtopics/keywords.

While positive categorical data were identified via the aforementioned methods, negative controls were generated by randomly selecting from alternative topics and ensuring no overlap. The categorical data were randomly split into training (80%) and test (20%) sets per test, and five tests were performed per topic by applying out-of-the-box logistic regression and multinomial naive Bayes and random forest algorithms from scikit-learn. These three algorithms were found to perform best on this binary classification task using out-of-the-box tests. Topics were only added to the record if all three methods agreed on the classification. The set size and test results using default tests from scikit-learn for each algorithm for each topic and subtopic for each of the five test runs can be found at https://github.com/outbreak-info/topic_classifier/blob/main/results/in_depth_classifier_test.tsv.

The efforts of our two volunteers suggested that non-experts were capable of thematically categorizing datasets; therefore, we built a simple interface to allow citizen scientists to thematically classify the datasets that were available in our collection at that point in time. Each dataset was assigned up to five topics by at least three different citizen scientists to ensure quality of the results. Citizen scientists were asked to prioritize specific topic categories over broader ones. Ninety citizen scientists recruited via either participation in the Mark2Cure project34 or a Scripps Research summer program participated in classifying 530 datasets pulled from Figshare and Zenodo, increasing the likelihood of quality submissions and decreasing the likelihood of abuse and false information. The citizen science-curation site was originally hosted at https://curate.outbreak.info. The code for the site can be found at https://github.com/outbreak-info/outbreak-info-resources/tree/master/citsciclassify. The citizen science classifications can be found at https://github.com/outbreak-info/topic_classifier/blob/main/data/subtopics/curated_training_df.pickle. To evaluate the quality of the citizen scientist classifications, we first filtered classifications where at least two or three of five curators agreed on the topic category. We then compared the results of their classification with predictions by an out-of-the-box algorithm that was trained on LitCovid-classified abstracts. A total of 186 of 530 classifications did not agree and were manually inspected; only about 10% of the categorization (54) was worse with citizen scientists over the predictions, and, in many cases, the curators provided more precise categorization. Full details of the evaluation are available at https://github.com/ghtsueg/curate_outbreak_data (https://doi.org/10.5281/zenodo.7442949). These classifications have been incorporated into the appropriate datasets in our collection and have been used to build our models for topic categorization. Basic in-group–out-group classification models were developed for each category using out-of-the-box logistic regression and multinomial naive Bayes and random forest algorithms available from scikit-learn. The topic classifier can be found at https://github.com/outbreak-info/topic_classifier (https://doi.org/10.5281/zenodo.7439573).

In addition to community curation of topic categorizations, we identified a citizen science effort, the COVID-19 Literature Surveillance...
Team (COVID-19 LST), that was evaluating the quality of COVID-19 related literature. The COVID-19 LST consists of medical students (many of which were in their third or fourth year), practitioners and researchers who evaluate publications on COVID-19 based on the Oxford Levels of Evidence criteria and write bottom line, up front summaries. With their permission, we integrated their outputs (daily reports or summaries and Levels of Evidence evaluations) into our collection. Although the project has since ended, the valuable work by this team was integrated without further evaluation due to their background and training.

We further integrated our publications by adding structured linkage metadata, connecting preprints and their peer-reviewed versions. We performed separate Jaccard’s similarity calculations on the title and/or text and authors for preprint (bioRxiv or medRxiv) versus LitCovid publications. We identified thresholds with high precision and low sensitivity and binned the matches into two groups: matched preprint or peer-reviewed publication versus ‘needs review’. We also leveraged NLM’s pilot preprint program to identify and incorporate additional matches. The code used for the preprint matching and the .XLSX file detailing the semi-automated and manual inspection of a sample of 1,500 matches from the results can be found at https://github.com/outbreak-info/outbreak.info/issues.

**Case study on variant research**

To identify research about variants, we used the keyword phrase ‘variant OR lineage’ in the Research Library and within the R package outbreakinfo. For Fig. 2a, resources were counted by @type (Publication, Dataset, ComputationalTool, ClinicalTrial, Protocol, Analysis). The number of resources was aggregated to the weekly level by the date of the latest update and normalized to all resources within the Library for that week, creating a proportion of the Library for that week (Fig. 2c). For variant-specific queries, the WHO-designated name was combined with its Pango lineage and all descendants, as specified by the Pango team in October 2022 (https://raw.githubusercontent.com/cov-lineages/lineages-website/master/data/lineages.yml). To decrease the likelihood of a spurious hit for the resource (for instance, a publication mentioning Alpha in the description but focusing only on Omicron), we used fielded queries to only search within the corresponding PubMed record and publication content (52 matches). The inspection confirmed that our threshold cutoff for preprint matching ensured the inclusion of a limited number of the most accurate matches at the cost of many more potential but lower-quality matches. Expected matches were linked via the correction property in our schema.

**Harmonization and integration of resources and genomic data**

The integration of genomic data from GISAID is discussed by Gangavarapu et al. We built separate API endpoints for our resources (metadata resource API) and genomics (genomic data API) using the BioThings SDK. Data are available via our API at http://api.outbreak.info and through our R package as described by Gangavarapu et al.

**Limitations**

While we have developed a framework for addressing resource volume, fragmentation and variety that can be applicable to future pandemics, our efforts during this framework exposed additional limitations in how data and metadata are currently collected and shared. Researchers have embraced preprints, but resources (especially datasets and computational tools) needed to replicate and extend research results are not linked in ways that are discoverable. Although many journals and funders have embraced dataset and source code submission requirements, the result is that the publication of datasets and software code is still heavily based in publications instead of in community repositories with well-described metadata to promote discoverability and reuse. In the outbreak.info Research Library, the largest research output by far is publications, while dataset submission logs in standardized repositories encouraged by the NIH such as ImmPort, Figshare and Zenodo. We hypothesize that this disparity between preprint and data sharing reflects the existing incentive structure, in which researchers are rewarded for writing papers and less for providing good, reusable datasets. Ongoing efforts to improve metadata standardization and encourage schema adoption (such as the efforts in the Bioschemas community) will help make resources more discoverable in the future, provided researchers adopt and use them. For this uptake to happen, fundamental changes in the incentive structure for sharing research outputs may be necessary. As with many web-based, open-source resource sites, bugs and browser-compatibility issues may arise without notice for less-popular browsers. Users can bring these issues to our attention by submitting them to our issue tracker on GitHub (https://github.com/outbreak-info/outbreak.info/issues).

**Comparison of the outbreak.info Research Library with other resources**

To illustrate how our resource fits into the COVID-19 resource landscape, we compare features from our Research Library with other COVID-19 multisource aggregation efforts (Supplementary Table 4) and provide a list of terms and features in Supplementary Table 5. We provide the most commonly searched sources (that is, filter by source) and resource types (that is, filter by resource type) (Supplementary Table 1a). Usage statistics for record views and filtering by source are available in Supplementary Table 1b. Filtering was the most popular feature added to the Library, with over a quarter of all queries using some sort of filtering (Supplementary Table 1c). Users were most likely to filter results by resource type, followed by keywords and source.

**Reporting summary**

Further information on research design is available in the Nature Portfolio Reporting Summary linked to this article.

**Data availability**

All metadata harvested and harmonized in the outbreak.info Research Library is freely available through an API (https://api.outbreak.info/) and in an associated R package (https://outbreak.info.github.io/R-outbreak-info/). The outbreak.info R package to access all the genomics and epidemiology data and Research Library metadata compiled and standardized on outbreak.info is available at https://github.com/outbreak-info/R-outbreak-info (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7343501). The code to create the API (https://api.outbreak.info) to access Research Library metadata and case and death...
data is available at https://github.com/outbreak-info/outbreak-api (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7434503). The harvester of bioRxiv and medRxiv preprint publications is available at https://github.com/outbreak-info/biorxiv (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439483). The harvester of clinical trials from https://clinicaltrials.gov is available at https://github.com/outbreak-info/clinical_trials (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439505). The harvester of COVID-19 LST level of evidence ratings is available at https://github.com/outbreak-info/covid19_LST_reports (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439527). The COVID-19 LST annotations code is available at https://github.com/outbreak-info/covid19_LST_annotations (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439515). The COVID-19 LST report data are available at https://github.com/outbreak-info/covid19_LST_report_data (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439521). The harvester for manually curated metadata from the DDE is available at https://github.com/biothings/discovery-app/blob/master/scripts/outbreak.py (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439590). The harvester from Figshare COVID-19 is available at https://github.com/outbreak-info/figshare (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439543). The harvester for COVID-19 collection of Harvard Dataverse is available at https://github.com/outbreak-info/dataverses (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439563). The harvester for analyses by Imperial College London is available at https://github.com/outbreak-info/icoimperial_college (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439454). The LitCovid publication harvester is available at https://github.com/outbreak-info/litcovid (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439565). The harvester of metadata for SARS-CoV-2 structures from the Protein Data Bank is available at https://github.com/outbreak-info/covid_pdb_datasets (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439549). The harvester of protocol metadata from protocols.io is available at https://github.com/outbreak-info/protocolsio (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439579). The harvester of clinical trials from WHO ICTR is available at https://github.com/outbreak-info/covid_who_clinical_trials/blob/master/parse.py (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439553). The reusable Research Library schemas for publications, datasets, clinical trials, protocols and analyses and associated data mappings are available at https://github.com/outbreak-info/outbreak.info-resources (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439569). The reusable Research Library tools for parsers are available at https://github.com/outbreak-info/outbreak_parsetools (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439577). The code to look up Altmetric ratings for outbreak.info resources is available at https://github.com/outbreak-info/covid_almetrics (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439533). The code to match preprints to their peer-reviewed publications is available at https://github.com/outbreak-info/outbreak_preprint_matcher (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439581). The machine learning topic classification of categories within the Research Library is available at https://github.com/outbreak-info/topic_classifier (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439573). The mapping logic used to classify clinical trial records using clinical trial-specific metadata is available at https://github.com/gtsueng/outbreak_CT_classifier (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7442988). The evaluation of citizen scientist efforts is available at https://github.com/gtsueng/curate_outbreak_data (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7442949). The code to generate the figures within this text, including for the case study, is available at https://github.com/outbreak-info/outbreak-resources-paper (version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439567).

Reporting Summary

Nature Research wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Research policies, see our Editorial Policies and the Editorial Policy Checklist.

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

☐ n/a Confirmed

☐ The exact sample size (n) for each experimental group/condition, given as a discrete number and unit of measurement

☐ A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly

☐ The statistical test(s) used AND whether they are one- or two-sided

Only common tests should be described solely by name; describe more complex techniques in the Methods section.

☐ A description of all covariates tested

☐ A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons

☐ A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals)

☐ For null hypothesis testing, the test statistic (e.g. F, t, r) with confidence intervals, effect sizes, degrees of freedom and P value noted

Give P values as exact values whenever suitable.

☐ For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings

☐ For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes

☐ Estimates of effect sizes (e.g. Cohen’s d, Pearson’s r), indicating how they were calculated

Our web collection on statistics for biologists contains articles on many of the points above.

Software and code

Policy information about availability of computer code

Data collection

All code used to generate the outbreak.info Research Library is freely available on GitHub (https://github.com/outbreak-info) under open source licenses. This code includes:

- outbreak.info web application: the code powering the outbreak.info front-end (https://github.com/outbreak-info/outbreak-info). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7343497.
- outbreak.info R package: R package to access all the genomics and epidemiology data and Research Library metadata compiled and standardized on outbreak.info (https://github.com/outbreak-info/R-outbreak-info). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7343501.
- api.outbreak.info: Code to create the application programming interface (API) to access Research Library metadata and cases & deaths data, available at api.outbreak.info (https://github.com/outbreak-info/outbreak-api). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7343503.
- bioRxiv and medRxiv: Harvester of bioRxiv and medRxiv pre-print publications (https://github.com/outbreak-info/biorxiv). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439483.
- ClinicalTrials.gov: Harvester of clinical trials from clinicaltrials.gov (https://github.com/outbreak-info/clinical_trials). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439505.
- COVID-19 LST: Harvester of COVID-19 LST level of evidence ratings (https://github.com/outbreak-info/covid19_LST_reports). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439527.
- COVID-19 LST Annotations (https://github.com/outbreak-info/covid19_LST_annotations). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439515.
- COVID-19 LST Report Data (https://github.com/outbreak-info/covid19_LST_report_data). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439521.
- Data Discovery Engine: Harvester for manually curated metadata from the Data Discovery Engine (https://github.com/biothings/discovery-app/blob/master/scripts/outbreak.py). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439590.
- Figshare: Harvester from Figshare COVID-19 (https://github.com/outbreak-info/covid_figshare). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439543.
Data analysis

All code used to generate the topic classification and preprint matcher within the outbreak.info Research Library is freely available on GitHub (https://github.com/outbreak-info) under open source licenses. This code includes:

- Preprint matcher: Code to match preprints to their peer-reviewed publications (https://github.com/outbreak-info/outbreak_preprint_matcher). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439581.
- Topic Classifier: Machine learning classification of categories within the Research Library (https://github.com/outbreak-info/topic_classifier). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439573.
- Clinical Trials mappings: Mapping logic used to classify clinical trial records using clinical trial-specific metadata (https://github.com/gtsueng/outbreak_CT_classifier). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7442988.
- Evaluation of Citizen Scientist Efforts: https://github.com/gtsueng/curate_outbreak_data. The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7442949.
- Figures within this Manuscript: Figures generated here, including for the case study (https://github.com/outbreak-info/outbreak-resources-paper). The version of the code used in this paper is available at https://doi.org/10.5281/zenodo.7439567.

Data

Policy information about availability of data

All manuscripts must include a data availability statement. This statement should provide the following information, where applicable:
- Accession codes, unique identifiers, or web links for publicly available datasets
- A list of figures that have associated raw data
- A description of any restrictions on data availability

All metadata harvested and harmonized in the outbreak.info Research Library is freely available through an API (http://api.outbreak.info/) and in an associated R package (https://outbreak-info.github.io/R-outbreak-info/).

Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

☑ Life sciences
☐ Behavioural & social sciences
☐ Ecological, evolutionary & environmental sciences

For a reference copy of the document with all sections, see nature.com/documents/nr-reporting-summary-list.pdf

Life sciences study design

All studies must disclose on these points even when the disclosure is negative.

| Sample size | We use all the resource metadata available on outbreak.info through our metadata harvesters, spanning sixteen data repositories. For generalist repositories, we use their COVID-19 collections to restrict the metadata to the metadata related to COVID-19. |
|-------------|---------------------------------------------------------------------------------------------------------------|
| Data exclusions | No data were excluded from analysis. |
| Replication | We have made all aspects of our code open source so users can deploy stand alone versions of our data pipelines, server, and the web interface. Further, we made all of the data accessible via an R package so users can perform their own analyses to either verify or replicate the results shown on the web interface. |
| Randomization | We use all the available metadata from outbreak.info and do not perform any statistical comparisons between any groups in the data. |
| Blinding | Since these analyses were based on publicly available metadata harvested from sixteen data repositories, the authors were blind to any |
# Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here, indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.
