Abstract
This paper studies the reducibility of almost-periodic Hamiltonian systems with small perturbation near the equilibrium which is described by the following Hamiltonian system:

\[
\frac{dx}{dt} = J[A + \varepsilon Q(t, \varepsilon)]x + \varepsilon g(t, \varepsilon) + h(x, t, \varepsilon).
\]

It is proved that, under some non-resonant conditions, non-degeneracy conditions, the suitable hypothesis of analyticity and for the sufficiently small \( \varepsilon \), the system can be reduced to a constant coefficients system with an equilibrium by means of an almost-periodic symplectic transformation.

Keywords: Almost-periodic matrix; Reducibility; KAM iteration; Hamiltonian systems; Small divisors

1 Introduction
In this paper we are studying the reducibility of the following almost-periodic Hamiltonian system:

\[
\frac{dx}{dt} = f[A + \varepsilon Q(t, \varepsilon)]x + \varepsilon g(t, \varepsilon) + h(x, t, \varepsilon), \quad x \in \mathbb{R}^{2N},
\] (1)

where \( f \) is an anti-symmetric symplectic matrix, \( A \) is a \( 2N \times 2N \) symmetric constant matrix with possible multiple eigenvalues, and \( Q(t) \) is an analytic almost-periodic symmetric \( 2N \times 2N \) matrix with respect to \( t \), \( g(t, \varepsilon) \) and \( h(x, t, \varepsilon) \) are almost-periodic \( 2N \)-dimensional vector-valued functions with respect to \( t \), with basic frequencies \( \omega = (\omega_1, \omega_2, \ldots) \) and \( h(x, t) = O(x^2) (x \to 0) \), and

\[
J = \begin{pmatrix} 0 & I_N \\ -I_N & 0 \end{pmatrix},
\]

where \( I_N \) is a \( N \times N \) identity matrix and \( \varepsilon \) is a sufficiently small parameter. First of all we will recall some previous results in the field of reducibility for analytic differential systems.
Consider the differential equation
\[ \frac{dx}{dt} = A(t)x, \quad x \in \mathbb{R}^m, \] (2)
where \( A(t) \) is an almost-periodic matrix. We call the transformation \( x = P(t)y \) almost-periodic Lyapunov–Perron (L-P) transformation, if \( P(t) \) is non-singular and \( P, P^{-1}, \) and \( \dot{P} \) are almost periodic. The transformed equation is
\[ \frac{dy}{dt} = C(t)y, \] (3)
where \( C = P^{-1}(AP - \dot{P}) \). If there exists an almost-periodic L-P transformation such that \( C(t) \) is a constant matrix, then we call equation (2) reducible.

In recent years, many researchers have devoted themselves to the study of the reducibility of finite dimensional systems by means of the KAM methods. The well-known Floquet theorem states that every periodic differential equation (2) can be reduced to a constant coefficients differential equation (3) by means of a periodic change of variables with the same period as \( A(t) \). But, if \( A(t) \) is quasi-periodic (q-p), then there is an example in [1] which illustrates that (2) is irreducible. In 1981, Johnson and Sell [2] showed that if \( A(t) \) the quasi-periodic matrix satisfies “full spectrum” conditions, then (2) is reducible. In 1992, Jorba and Simó [3] proved the reducibility result of linear quasi-periodic systems like (5) for the constant matrix \( A \) with distinct eigenvalues. In 1999, Xu [4] proved the reducibility result of linear quasi-periodic systems like (5) for the constant matrix \( A \) with multiple eigenvalues. In 1996, Jorba and Simó [5] considered the quasi-periodic system
\[ \frac{dx}{dt} = [A + \varepsilon Q(t)]x + \varepsilon g(t) + h(x,t), \quad x \in \mathbb{R}^m, \] (4)
where the constant matrix \( A \) has distinct eigenvalues. They proved that system (4) is reducible for \( \varepsilon \in E \) using the non-resonant conditions and non-degeneracy conditions, where \( E \) is the non-empty Cantor subset such that \( E \subset (0,\varepsilon_0) \). Instead of quasi-periodic reduction to a constant coefficient linear systems, in 1996, Xu and You [6] proved the reducibility of the linear almost-periodic differential equation
\[ \frac{dx}{dt} = [A + \varepsilon Q(t)]x, \quad x \in \mathbb{R}^m, \] (5)
where the constant matrix \( A \) has different eigenvalues and \( Q(t) \) is an \( m \times m \) analytic almost-periodic matrix with frequencies \( \omega = (\omega_1,\omega_2,\ldots) \). Under some small divisor conditions and for most sufficiently small \( \varepsilon \), they proved that system (5) is reducible to the constant coefficient system by an affine almost-periodic transformation. In 2013, Qiu and Li [7] considered the following non-linear almost-periodic differential equation:
\[ \frac{dx}{dt} = [A + \varepsilon a(t)]x^{2n+1} + h(x,t,\varepsilon) + f(x,t,\varepsilon), \quad x \in \mathbb{R}, \] (6)
where \( n \geq 0 \) is an integer, \( A \) is a positive number, \( \varepsilon \) is a small parameter, \( h \) is a higher order term, and \( f \) is a small perturbation term. They proved that under some suitable conditions and using the KAM method system (6) can be reduced to a suitable normal form with zero
as an equilibrium point by an affine almost-periodic transformation, so it has an almost-periodic solution near zero.

In 2015, Li et al. [8] considered the following analytic quasi-periodic Hamiltonian system:

$$\frac{dx}{dt} = [A + \varepsilon Q(t)]x + \varepsilon g(t) + h(x,t), \quad x \in \mathbb{R}^{2m},$$  

(7)

where the constant matrix $A$ has multiple eigenvalues, $Q, g,$ and $h$ are quasi-periodic with respect to $t$ and $h = O(x^2)$ ($x \to 0$). They proved that by using the non-resonant conditions, non-degeneracy conditions, and a suitable hypothesis of analyticity, the Hamiltonian system (7) can be changed to another Hamiltonian system with an equilibrium by a q-p symplectic transformation.

In this paper we are going to extend the results of [5] to the almost-periodic Hamiltonian system (1).

This paper is organized as follows. In Sect. 2, statement of the main result is given, in Sect. 3 we give some lemmas which are essential for the proof of the main result, in Sect. 4 the first KAM step is given, in Sect. 5 the main result is proved, and finally, in Sect. 6 conclusion of the paper is given.

1.1 Definitions and notations

To state our main result, we need some definitions and notations.

**Definition 1.1** We say that a function $f$ is a quasi-periodic function of time $t$ with basic frequencies $\omega = (\omega_1, \omega_2, \ldots, \omega_d)$ if $f(t) = F(\theta_1, \theta_2, \ldots, \theta_d)$, where $F$ is $2\pi$ periodic in all its arguments $\theta_j = \omega_j t$ for $j = 1, 2, \ldots, d$. $f$ will be called analytic quasi-periodic in a strip of width $\rho$ if $F$ is analytic on $D_\rho = \{\theta| |\Im \theta_j| \leq \rho, j = 1, 2, \ldots, d\}$. In this case we denote the norm by $\|f\|_\rho = \sum_{k \in \mathbb{Z}^d} |F_k|e^{\rho|k|}$. A function $f$ is almost-periodic if $f(t) = \sum_{n=1}^{\infty} f_n(t)$, where $f_n(t)$ are all quasi-periodic for $n = 1, 2, \ldots$.

**Definition 1.2** Suppose that $A(t) = (a_{ij}(t))$ is a quasi-periodic $m \times m$ matrix. If every $a_{ij}(t)$ is analytic on $D_\rho$, then we call $A(t)$ analytic on $D_\rho$. The norm of $A(t)$ is defined as follows:

$$\|A(t)\|_\rho = m \times \max_{1 \leq i \leq m} \|a_{ij}(t)\|_\rho.$$  

If $A$ is a constant matrix, the norm of $A$ is defined as follows:

$$\|A\| = m \times \max_{1 \leq i \leq m} |a_{ij}|.$$  

Write $B(0,b) = \{x \in \mathbb{C}| |x| \leq b\}$ and $\Delta_{b,\rho} = B(0,b) \times D_\rho$.

**Definition 1.3** Let $h(x,t)$ be real analytic in $x$ and $t$ on $\Delta_{b,\rho}$, and let $h(x,t)$ be quasi-periodic with respect to $t$ with frequency $\omega$. Then $h(x,t)$ can be expanded as a Fourier series as follows:

$$h(x,t) = \sum_{k \in \mathbb{Z}^d} h_k(x)e^{i(k,\theta)}.$$
Then
\[ \|h\|_{\Delta,b,\rho} = \sum_{k \in \mathbb{Z}^d} |h_k|_{b^e} \rho^{|k|}, \]
where \( h_k(x) = \sum_{n=0}^{\infty} h_{nk} x^n \) and \( |h_k|_b = \sup_{x \in B(0,b)} \sum_{n=0}^{\infty} |h_{nk}| |x|^n \). It is easy to see that
\[ \|h_1 h_2\|_{\Delta,b,\rho} \leq \|h_1\|_{\Delta,b,\rho} \|h_2\|_{\Delta,b,\rho}. \]

The aim of the study is to develop the reducibility for the almost-periodic non-linear Hamiltonian system (1). To take over the difficulty from the infinite frequency which generates the small divisors problem, we need a stronger norm. Inspired by the works of [4, 5], and [8], in this paper, we allow \( Q, g, \) and \( h \) to be the classes of almost-periodic matrices. Our study is about the reducibility of almost-periodic Hamiltonian systems to [4] and [8]. So, the usual LP transformation for KAM iteration should not only be almost-periodic but also symplectic, which preserves the Hamiltonian structure. For this purpose, let us introduce “spatial structure”, “approximation function”, and some related definitions.

**Definition 1.4** ([9]) Let \( \tau \) be a set of some subsets of the natural number set \( \mathbb{N} \). Then \( (\tau, [\cdot]) \) is called a finite spatial structure in \( \mathbb{N} \) if \( \tau \) satisfies:
1. \( \emptyset \in \tau; \)
2. If \( \Lambda_1, \Lambda_2 \in \tau \), then \( \Lambda_1 \cup \Lambda_2 \in \tau; \)
3. \( \bigcup_{\Lambda \in \tau} \Lambda = \mathbb{N}, \)
and \( [\cdot] \) is a weight function defined on \( \tau \) such that \( [\emptyset] = 0, [\Lambda_1 \cup \Lambda_2] \leq [\Lambda_1] + [\Lambda_2]. \)

Denote the weight value by \( [k] = \inf_{\Lambda \in \tau} \sup_{k \subseteq \Lambda} [\Lambda] \). Write \( |k| = \sum_{s \in \tau} |k_s|. \)

**Definition 1.5** ([4]) If \( U(t) = \sum_{\Lambda \in \tau} U_{\Lambda}(t), \) where \( U_{\Lambda}(t) \) are quasi-periodic matrices with basic frequencies \( \omega_{\Lambda} = \{\omega_s | s \in \Lambda\} \), then \( U(t) \) is known as an almost-periodic matrix with spatial structure \( (\tau, [\cdot]) \) and basic frequencies \( \omega \), which is the maximum subset of \( \cup \omega_{\Lambda} \) in the sense of integer modular. Denote the average of \( U(t) \) by \( \overline{U} \), where
\[ \overline{U} = \lim_{T \to \infty} \frac{1}{2T} \int_{-T}^{T} U(t) \, dt. \]
Let \( U(t) = \sum_{\Lambda \in \tau} U_{\Lambda}(t), \) for \( \varepsilon > 0, \rho > 0, \)
\[ \left\| U(t) \right\|_{\varepsilon, \rho} = \sum_{\Lambda \in \tau} e^{\varepsilon |\Lambda|} \left\| U_{\Lambda}(t) \right\|_{\rho} \]
is called a weight norm with finite spatial structure \( (\tau, [\cdot]) \).

**Definition 1.6** ([10]) \( \Delta \) is called an approximation function if
1. \( \Delta : [0, \infty) \to [1, \infty) \) is an increasing function and it satisfies \( \Delta(0) = 1; \)
2. \( \log \frac{\Delta(t)}{t} \) is decreasing on \( [0, \infty); \)
3. \( \int_{0}^{\infty} \log \frac{\Delta(t)}{t} \, dt < \infty. \)
Remark If $\Delta$ is an approximation function, then so is $\Delta^4$.

Definition 1.7 Let $h(x,t) = \sum_{\lambda \in \tau} h_\lambda(x,t)$ with frequency $\omega = (\omega_1, \omega_2, \ldots)$ and with finite spatial structure $(\tau, [\cdot])$, for $z > 0$, $\rho > 0$,

$$\|h(x,t)\|_{\Delta^4} = \sum_{\lambda \in \tau} \|h_\lambda(x,t)\|_{\Delta^4}$$

is known as the weight norm of $h(x,t)$.

Definition 1.8 A matrix $S$ is said to be symplectic if $SJST = J$, where $S^T$ represents the transpose of $S$ and $J = (\begin{smallmatrix} 0 & I_N \\ -I_N & 0 \end{smallmatrix})$, where $I_N$ is an $N \times N$ identity matrix.

For a map $\psi(t,x) : \mathbb{R}^{2N} \to \mathbb{R}^{2N}$, let $\frac{\partial \psi}{\partial x}$ denote the Jacobian of $\psi$ with respect to $x$, that is, $\frac{\partial \psi}{\partial x} = (\frac{\partial \psi}{\partial x})_{2N \times 2N}$.

Definition 1.9 $\psi(t,x)$ is symplectic if and only if the Jacobian of $\psi$ with respect to $x$ is symplectic, i.e., $\frac{\partial \psi}{\partial x} \frac{\partial \psi}{\partial x}^T = J$.

Definition 1.10 A matrix $A$ is said to be Hamiltonian if and only if $A = JB$, where $B$ is a symmetric matrix and $J$ is defined as above.

For our problem, the non-resonant conditions will be

$$|\lambda_s - \lambda_j - \sqrt{-1}(k, \omega)| \geq \frac{\alpha}{\Delta^4(|k|)\Delta^4(|l|)}$$

for all $1 \leq s \neq j \leq 2N$ and $k \in \mathbb{Z}^N \setminus \{0\}$, where $\lambda_1, \lambda_2, \ldots, \lambda_{2N}$ are the eigenvalues of $JA$, $\omega$ is the basic frequencies of $Q(t)$, $\Delta(t)$ is an approximation function satisfying $\sum_{k \in \mathbb{Z}^N} \frac{1}{\Delta^4(|k|)\Delta^4(|k|)} < \infty$ and $\alpha$ is a small positive constant. From [4] and [9], we can choose the weight function

$$[A] = 1 + \sum_{s \in \Lambda} \log^p (1 + |s|), \quad p > 2.$$

2 Statement of the main result

Theorem 2.1 Suppose that the Hamiltonian system (1) in which $JA$ is a Hamiltonian matrix with possible multiple eigenvalues, $Q(t) = \sum Q_\lambda(t)$ and $g(t) = \sum g_\lambda(t)$ are analytic almost-periodic matrices with respect to $t$ on $D_\rho$, and $h(x,t) = \sum h_\lambda(x,t)$ is analytic almost-periodic matrix with respect to $t$ and $x$ on $\Delta_{\rho,\rho}$ with basic frequencies $\omega = (\omega_1, \omega_2, \ldots)$ and has the spatial structure $(\tau, [\cdot])$ which depends continuously on the small parameter $\varepsilon$. Suppose that $JA$ is a $2N \times 2N$ matrix with possible multiple eigenvalues $\lambda_1, \lambda_2, \ldots, \lambda_{2N}$ that can be diagonalized and the multiplicity of the eigenvalues $\lambda_{r,s}$ that $r_1 + r_2 + \cdots + r_l = 2N$, $\lambda_{r,s} \neq 0$, and $\lambda_{r,s} \neq \lambda_{r',s'}$ with $s' \neq r'$ and $1 \leq s', r' \leq l$. Moreover, assume that $h(x,t, \varepsilon)$ is analytic with respect to $x$ on the closed ball $B_\varepsilon(0)$, $h(0, t, \varepsilon) = 0$, and $D_\varepsilon h(0, t, \varepsilon) = 0$ and $\varepsilon \in (0, \varepsilon_0)$ is a parameter. If

1. There exists $z > 0$ such that $\|Q(t)\|_{L^z} < \infty$, $\|g(t)\|_{L^z} < \infty$;
2. **(Non-resonant conditions)** \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_{2N}) \) and \( \omega = (\omega_1, \omega_2, \ldots) \) satisfy

\[
\begin{align*}
|\lambda_s - \sqrt{-1}(k, \omega)| & \geq \frac{\alpha_0}{\Delta(|k|)\Delta(|k|)}, \\
|\lambda_s - \lambda_j - \sqrt{-1}(k, \omega)| & \geq \frac{\alpha_0}{\Delta(|k|)\Delta(|k|)}
\end{align*}
\]

for all \( 1 \leq s, j \leq 2N, k \in \mathbb{Z}^N \setminus \{0\}, \alpha_0 > 0 \) is a small constant and \( \Delta(t) \) is an approximation function;

3. **(Non-degeneracy conditions)** Suppose that the unique solution of \( \dot{x} = JAx + \varepsilon g(t) \) is denoted by \( x \). Assume that \( f(A + \varepsilon Q) \) has \( 2N \) different eigenvalues \( \lambda_{1}^{\pm}(\varepsilon) \)

\( (1 \leq s \leq 2N) \) which satisfy

\[
|\lambda_{k_1}(\varepsilon) - \lambda_{k_2}(\varepsilon)| \geq 2\eta \varepsilon > 0, \eta_2 \geq \frac{|d\lambda_{k_2}(\varepsilon)|}{\varepsilon} \geq \eta_1 > 0,
\]

where \( k, k_1, k_2 = 1, 2, \ldots, 2N, k \neq k_2, \varepsilon \in (0, \varepsilon_0) \), and \( \eta, \eta_1, \) and \( \eta_2 \) are positive constants. Let \( Q^*(t) = Q(t) + \frac{1}{\varepsilon}D_{x}h(x, t) \) and \( \overline{Q} \) be the average of \( Q^*(t) \).

4. \( \|D_{x}h(x, t, \varepsilon)\|_{L^1_{\lambda, b, \rho}} \leq K \), where \( \varepsilon \in (0, \varepsilon_0) \) and \( x \in B_{b}(0) \).

Then there exists a Cantor subset \( E \subset (0, \varepsilon_0) \) with positive Lebesgue measure such that the Hamiltonian system (1) is reducible for \( \varepsilon \in E \), i.e., there exists an almost-periodic symplectic transformation \( x = \psi(t, \varepsilon)y + \varphi(t, \varepsilon) \), where \( \psi(t, \varepsilon) \) and \( \varphi(t, \varepsilon) \) are almost-periodic with basic frequencies and spatial structure \((\tau, [\cdot])\) as \( Q(t) \), which transforms (1) into the Hamiltonian system

\[
\frac{dy}{dt} = A_{\varepsilon}(\varepsilon) + h_{\varepsilon}(y, t, \varepsilon),
\]

where \( A_{\varepsilon}(\varepsilon) \) is the constant matrix and \( h_{\varepsilon}(y, t, \varepsilon) \) is of order two in \( y \). Furthermore, for small enough \( \varepsilon_0 \), the relative measure of \( E \) in \( (0, \varepsilon_0) \) is close to 1.

**Remark** In general, we suppose that \( g(t), Q(t), \) and \( h(x, t) \) depend on \( \varepsilon \), but for simplicity, in the following we do not represent this dependence.

## 3 Some lemmas

In this section, we will give some results in the form of lemmas which are useful for the proof of Theorem 2.1.

**Lemma 3.1** ([4]) Suppose that \( U \) and \( R \) are almost-periodic matrices, and they have the same spatial structure and the same frequencies. If \( \|U\|_{z, \rho} < +\infty, \|R\|_{z, \rho} < +\infty \), then \( UR \) is an almost-periodic matrix and has the same spatial structure and the same frequencies with \( U \) and \( R \), and

\[
\|UR\|_{z, \rho} \leq \|U\|_{z, \rho}\|R\|_{z, \rho}.
\]

**Lemma 3.2** ([4]) Suppose that an analytic almost-periodic matrix \( U(t) \) has the spatial structure \((\tau, [\cdot])\), and for \( z > 0, \rho > 0, \|U\|_{z, \rho} < +\infty \). Then, for the average of \( U(t) \), we have \( \|U\|_{z, \rho} < +\infty \).

\[
\|U\|_{z, \rho} < +\infty.
\]
Lemma 3.3 ([5]) Let $\lambda_1, \lambda_2, \ldots, \lambda_{2l}$ be the eigenvalues of $B_1$ satisfying $|\lambda_1| > 2v, |\lambda_2 - \lambda_1| > 2v$, and $v > 0$ with $s \neq j$. Consider $B_0$ to be a matrix such that $B_0^{-1}B_1B_0 = \text{diag}(\lambda_1, \ldots, \lambda_{2l})$. Define $\beta_0 = \max\{\|B_0\|, \|B_0^{-1}\|\}$. Let $\varsigma$ be a value such that $0 < \varsigma < \frac{2v}{(\omega - 1)\beta_0}$. Then, if $JA$ verifies $\|JA - B_1\| < \varsigma$, the following results hold:

1. If $\lambda_j, \lambda_{j'}, \ldots, \lambda_{j''}$ are the eigenvalues of $JA$, we have $|\lambda_j| > v, |\lambda_j - \lambda_s| > v, s \neq j$.

2. There exists a non-singular matrix $B$ such that $B^{-1}JAB = \text{diag}(\lambda_1, \lambda_2, \ldots, \lambda_{2l})$, which satisfies $\|B\|, \|B^{-1}\| \leq \beta$, where $\beta = 2\beta_0$.

Remark Indeed, by Gersgorin’s lemma, the result 1 of Lemma 3.3 can be obtained. In our case, if the constant matrix $A_0$ can be diagonalized, then the eigenvalues $\lambda_n^0$ of $A_0$ satisfy $|\lambda_n^0| \geq 2\eta_3 > 0$ with a constant $\eta_3$, $\forall s$, and $A_n - A_0 = O(\varepsilon)$, where $n \geq 1$ represents the $n$th KAM step. So, by Gersgorin’s lemma, we have that, for small enough $\varepsilon$, the eigenvalues $\lambda_n^s$ of $A_n$ satisfy $|\lambda_n^s| \geq \eta_3 > 0, \forall s$. In this article, we denote $v = \eta \varepsilon$ and $B_1 = A_1$. Then Lemma 3.3 holds and, moreover, in this article, $\beta_0$ is a bounded and positive constant.

Lemma 3.4 Consider the system

$$
\dot{x} = JAx + \varepsilon g(t), \quad x \in \mathbb{R}^{2N},
$$

where $JA \in B_{\varsigma}(A_1)$ and $\varsigma$ is given by Lemma 3.3. Let the eigenvalues of $JA$ be $\lambda_j$, where $|\lambda_j| \geq \eta_3 > 0$ with a constant $\eta_3$, $\forall s$. Moreover, $g(t) = \sum g_j(t)$ is analytic almost-periodic on $D_\rho$ with frequencies $\omega = (\omega_1, \omega_2, \ldots)$ and has the spatial structure $(\tau, [\cdot])$. Suppose

$$
|\lambda_j| - \frac{1}{2}(J, \omega) \geq \frac{\alpha}{\Delta_{\lambda}(\|k\|)\Delta_{\lambda}(\|k\|)}
$$

(12)

$\forall k \in \mathbb{Z}^N\setminus\{0\}$, a constant $\alpha > 0$ and an approximation function $\Delta(t)$. Let $0 < \beta < \rho, 0 < \varepsilon < z$. So, for equation (11), a unique analytic almost-periodic solution $x(t)$ exists with the same spatial structure and the same frequency as $g(t)$ which satisfies $\|x\|_{z, \tau, \rho, \theta} \leq c\|g\|_{z, \rho, \theta}$, where $\Gamma(\rho) = \sup_{t \geq 0} [\Delta_{\lambda}(t)e^{\rho t}]$ and a constant $c > 0$.

Proof Making the change of variables $x = By$ and by defining $h(t) = B^{-1}g(t)$, system (11) can be written as

$$
\dot{y} = Dy + \varepsilon h(t), \quad y \in \mathbb{R}^{2N},
$$

(13)

where $D = B^{-1}(JAB) = \text{diag}(\lambda_1, \lambda_2, \ldots, \lambda_{2N})$. Let

$$
y_{\lambda} = (y_{\lambda}^j), \quad (y_{\lambda}^{\lambda,k}) = \sum_{\text{supp}k \subseteq \Lambda} y_{\lambda}^{\lambda,k} e^{\sqrt{\tau}(k,\beta)},
$$

$$
h_{\lambda} = (h_{\lambda}^j), \quad (h_{\lambda}^{\lambda,k}) = \sum_{\text{supp}k \subseteq \Lambda} h_{\lambda}^{\lambda,k} e^{\sqrt{\tau}(k,\beta)},
$$

where $\theta = \omega t$. 
Substitute these into $\dot{y}_\lambda = D y_\lambda + \varepsilon h_\lambda$, and by equating the coefficients on both sides, we obtain
\[
y^j_{\lambda k} = \frac{H^j_{\lambda k}}{\lambda - \sqrt{-1} \{k, \omega\}}.\]

So, by equation (12), we get
\[
\|y^j_{\lambda k}\|_{\rho-\bar{\pi}} \leq \varepsilon \left( \frac{1}{\eta_3} + \frac{1}{\sum \supp k \in \Lambda} \frac{\Delta^4(k) e^{-\eta_1|k|}}{\alpha} \right) \|H^j_{\lambda k} e^{\rho|k|}\|
\leq c \varepsilon \frac{\Gamma(\bar{\pi}) \Delta^4([\Lambda])}{\alpha} \|y^j_{\lambda k}\|_{\rho},
\]
where $c > 0$ is a constant. Thus
\[
\|y_\lambda\|_{\rho-\bar{\pi}} \leq c \varepsilon \frac{\Gamma(\bar{\pi}) \Delta^4([\Lambda])}{\alpha} \|H_\lambda\|_{\rho}.
\]

Let $y = \sum \lambda \in \tau y_\lambda$. From Definition 1.2, we have
\[
\|y\|_{\bar{\pi}-\bar{\pi}} = \sum \lambda \in \tau \|y_\lambda\|_{\rho-\bar{\pi}} e^{\varepsilon|\lambda|}
\leq c \varepsilon \sum \lambda \in \tau \frac{\Gamma(\bar{\pi}) \Delta^4([\Lambda])}{\alpha} \|H_\lambda\|_{\rho} e^{\varepsilon|\lambda|}
\leq c \varepsilon \frac{\Gamma(\bar{\pi}) \Gamma(2)}{\alpha} \|y\|_{\bar{\pi}-\bar{\pi}}.
\]

By Remark of Lemma 3.3, we have $\|B\|_\rho \|B^{-1}\|_{\rho} \leq c_0$, where $c_0 > 0$ is a constant. Then, since $\|H\|_{\rho} \leq \|B^{-1}\|_{\rho} \|g\|_{\bar{\pi}-\bar{\pi}}$ and $\|x\|_{\bar{\pi}-\bar{\pi}} \leq \|B\|_{\rho} \|y\|_{\bar{\pi}-\bar{\pi}}$, we have
\[
\|x\|_{\bar{\pi}-\bar{\pi}} \leq c \varepsilon \frac{\Gamma(\bar{\pi}) \Gamma(2)}{\alpha} \|g\|_{\bar{\pi}-\bar{\pi}}.
\]

**Lemma 3.5** Let $h : B_b(0) \subset \mathbb{R}^l \to \mathbb{R}^l$ be a $C^2$ function that satisfies $h(0) = 0$, $\frac{d h(0)}{dx} = 0$, $\|\frac{d^2 h(0)}{dx^2}\| \leq K$, $\forall x \in B_b(0)$, where $B_b(0)$ is a ball centered at 0 and having radius $b$, where $K$ is a constant. Then $\|h(x)\| \leq \frac{K}{2} \|x\|^2$, $\|\frac{d h(x)}{dx}\| \leq K \|x\|$.

For the proof of Lemma 3.5, see [5].

**Lemma 3.6** Let
\[
\dot{p} = JAP - PJ A + Q,
\]
where $JA$ is a $2N \times 2N$ Hamiltonian matrix and $JA \in B_{\zeta}(A_1)$, the eigenvalues of $A_1$ are $\lambda_{11}^1, \lambda_{12}^1, \ldots, \lambda_{1N}^1$ with $|\lambda_{1j}^1| > 2 \eta_1$ and $|\lambda_{1j}^1 - \lambda_{1j}^1| > 2 \eta_1$ for $s \neq j$, and $\zeta$ can be found in Lemma 3.3. Let $\lambda_1, \ldots, \lambda_\tau, 1 \leq s \leq 2N$, with $\lambda_1 \neq 0$ be the eigenvalues of $JA$. Moreover, $Q(t) = \sum \lambda \in \tau Q_\lambda(t)$ is an analytic almost-periodic Hamiltonian matrix on $D_\rho$ with frequencies $\omega = (\omega_1, \omega_2, \ldots)$ and with finite spatial structure $(\tau, [\cdot])$. $Q = 0$, where $Q$ is the average of $Q(t)$. Let
\[
|\lambda_\xi - \lambda_\psi - \sqrt{-1} \{k, \omega\}| \geq \frac{\alpha}{\Delta^4(|k|) \Delta^4(|\lambda|)}.
\]
\( \forall k \in \mathbb{Z}^N \setminus \{0\}, \alpha > 0 \) is a constant and \( \Delta(t) \) is an approximation function, and \( |\lambda_{k_1} - \lambda_{k_2}| \geq \eta \varepsilon, k_1 \neq k_2 \). Let \( 0 < \bar{\rho} < \rho, 0 < \bar{z} < z \). Then we have a unique analytic almost-periodic Hamiltonian matrix \( P(t) \) with the same spatial structure and the same frequencies as \( Q(t) \), which solves equation (14) and satisfies

\[
\| P \|_{\bar{z}, \rho - \bar{\rho}} \leq c \frac{\Gamma(\bar{\rho}) \Gamma(\bar{z})}{\alpha} \| Q \|_{\bar{z}, \rho},
\]

where \( \Gamma(\rho) = \sup_{t \geq 0} [\Delta^4(t)e^{-\rho t}] \) and \( c > 0 \) is a constant.

**Proof.** We can suppose that the matrix \( B \) is as in Lemma 3.4. Making the setting \( P = BV B^{-1} \) and \( R = B^{-1}QB \), equation (14) can be written as

\[
\dot{V} = DV - VD + R,
\]

where \( D = \text{diag}(\lambda_1, \lambda_2, \ldots, \lambda_{2N}) \). Let

\[
R_A = \left( r^{ij}_A \right), \quad (r^{ij}_A) = \sum_{\text{supp} k \subset \Lambda} r^{ij}_{Ak} e^{i\theta(k,\omega)},
\]

\[
V_A = \left( v^{ij}_A \right), \quad (v^{ij}_A) = \sum_{\text{supp} k \subset \Lambda} v^{ij}_{Ak} e^{i\theta(k,\omega)},
\]

where \( \theta = \omega t \). Substitute these into \( \dot{V}_A = DV_A - V_A D + R_A \), and by equating the coefficients on both sides, we have \( v^{ij}_{A0} = 0 \); or

\[
v^{ij}_{Ak} = \frac{r^{ij}_{Ak}}{\lambda_i - \lambda_j - \sqrt{-1}(k,\omega)} \quad \text{for } k \neq 0.
\]

As \( Q \) is analytic on \( D_\rho \), therefore \( R = B^{-1}QB \) is also analytic on \( D_\rho \). So, by using equation (15), we have

\[
\| v^{ij}_A \|_{\rho - \bar{\rho}} \leq \sum_{\text{supp} k \subset \Lambda} \frac{\Delta^4(|k|)e^{-\rho |k|}}{\alpha} \Delta^4(|k|) |r^{ij}_{Ak}| e^{i\theta(k)}
\]

\[
\leq \frac{\Gamma(\bar{\rho}) \Delta^4(|\Lambda|)}{\alpha} \| r^{ij}_{Ak} \|_{\rho}.
\]

Thus

\[
\| P_A \|_{\rho - \bar{\rho}} \leq \frac{\Gamma(\bar{\rho}) \Delta^4(|\Lambda|)}{\alpha} \| R_A \|_{\rho}.
\]

Let \( V = \sum_{A \in \tau} V_A \). From Definition 1.4, we have

\[
\| V \|_{\bar{z}, \rho - \bar{\rho}} \leq \sum_{A \in \tau} \| V_A \|_{\rho - \bar{\rho}} e^{i\bar{z}|\Lambda|}
\]

\[
\leq \sum_{A \in \tau} \frac{\Gamma(\bar{\rho}) \Delta^4(|\Lambda|)}{\alpha} \| R_A \|_{\rho} e^{i|\Lambda| - \bar{z}|\Lambda|}
\]

\[
\leq \frac{\Gamma(\bar{\rho}) \Gamma(\bar{z})}{\alpha} \| R \|_{\bar{z}, \rho}.
\]
By Remark of Lemma 3.3, we have \( \|B\|\|B^{-1}\| \leq c_0 \), where \( c_0 > 0 \) is a constant. Then, by using Lemmas 3.1 and 3.2, we can write

\[
\|P\|_{z,\rho,\tau} \leq \|B\|\|V\|_{z,\rho,\tau}\|B^{-1}\|
\]

and

\[
\|R\|_{z,\rho} \leq \|B^{-1}\|\|Q\|_{z,\rho}\|B\|.
\]

Thus,

\[
\|P\|_{z,\rho,\tau} \leq c \frac{\Gamma(\tau)\Gamma(\rho)}{\alpha} \|Q\|_{z,\rho}.
\]

Now we prove that \( P = \sum_{\lambda \in \tau} P_\lambda \) is Hamiltonian. To prove \( P \) is Hamiltonian, we need to prove that \( P_j \) is symmetric in \( P_j = J^{-1} P \). As \( JA \) and \( Q = \sum_{\lambda \in \tau} Q_\lambda \) are Hamiltonian, then by definition, we can write \( Q = JQ_J \), where \( A \) and \( Q_J \) are symmetric. Below we prove that \( P_j \) is symmetric. Substituting \( P = JP_j \) and \( Q = JQ_j \) into equation (14), we have

\[
\dot{P}_j = AJP_j - P_j JA + Q_j, \tag{16}
\]

and transposing equation (16), we have

\[
\dot{P}_j^T = AJP_j^T - P_j^T JA + Q_j.
\]

It is easy to see that \( P_j \) and \( JP_j^T \) are solutions of equation (14); moreover, \( P_j = JP_j^T = 0 \). Since the solution of equation (14) is unique with \( P = 0 \), we have that \( P_j = JP_j^T \), which proves that \( P \) is Hamiltonian.

**Lemma 3.7** Consider the Hamiltonian system

\[
\frac{dx}{dt} = f[A + \varepsilon Q(t)]x + \varepsilon g(t) + h(x, t), \tag{17}
\]

where \( JA \) is a Hamiltonian matrix of dimension \( 2N \times 2N \), \( JA \in B_\zeta(A_1) \) with \( \zeta \) being given by Lemma 3.3, and \( \lambda_s \) are eigenvalues of \( JA \) with \( |\lambda_s| \geq \eta_3 > 0, \forall 1 \leq s \leq 2N \). Suppose that \( Q(t) = \sum_{\lambda \in \tau} Q_\lambda(t), g(t) = \sum_{\lambda \in \tau} g_\lambda(t) \) are almost-periodic on \( D_\varsigma \), and \( h(x, t) = \sum_{\lambda \in \tau} h_\lambda(x, t) \) is an almost-periodic analytic matrix with respect to \( t \) and \( x \) on \( \Delta_{\eta_2} \) with frequencies \( \omega = (\omega_1, \omega_2, \ldots) \) and has a finite spatial structure \( (\delta, [\cdot]) \). Suppose also that \( h(x, t) \) is analytic with respect to \( x \) on \( B_0(0) \) and satisfies \( \|D_\varsigma h(x, t, \varepsilon)\| \leq K, \forall x \in B_0(0) \). Moreover,

\[
|\lambda_s - \sqrt{-1}(k, \omega)| \geq \frac{\alpha}{\Delta^4(|k|)\Delta^4(|k|)}
\]

\( \forall k \in \mathbb{Z}^N \setminus \{0\} \), with a constant \( \alpha > 0 \) and an approximation function \( \Delta(t) \). Let \( 0 < \sigma < \rho, 0 < \varsigma < \varsigma \). Then, a symplectic change of variables \( x = y + \chi \) exists, so that the Hamiltonian system (17) can be transformed into the Hamiltonian system

\[
\frac{dy}{dt} = f[A + \varepsilon Q^*]y + \varepsilon^2 \tilde{g}^*(t) + h^*(y, t)
\]
such that
\[
\| Q^* \|_{z_0, \rho, \varpi} \leq \| Q \|_{z_0, \rho} + c K \frac{\Gamma(\varpi)}{\alpha} \| g \|_{z_0, \rho}
\]
and
\[
\| g^* \|_{z_0, \rho, \varpi} \leq c \frac{\Gamma(\varpi)}{\alpha} \| Q \|_{z_0, \rho} \| g \|_{z_0, \rho} + c K \left( \frac{\Gamma(\varpi)}{\alpha} \right)^2 \| g \|^2_{z_0, \rho},
\]
where \( y \in B_{b_1}(0), b_1 = b - \| x \|_{z_0, \rho, \varpi}, \) and \( \Gamma(\rho) = \sup_{t \geq 0} | \Delta^4(t) e^{-\rho t} |. \)

**Proof** Consider that the equation \( \frac{dx}{dt} = J Ax + \epsilon g(t) \) has solution \( x. \) Using Lemma 3.4, we get
\[
\| x \|_{z_0, \rho, \varpi} \leq c \frac{\Gamma(\varpi)}{\alpha} \| g \|_{z_0, \rho}.
\]

Using the symplectic transformation \( x = y + \chi, \) equation (17) becomes
\[
\frac{dy}{dt} = J [A + \epsilon Q^*] y + \epsilon^2 g^*(t) + h^*(y, t),
\]
where
\[
g^*(t) = \frac{1}{\epsilon^2} h(x, t) + \frac{1}{\epsilon} Q(t) x(t),
\]
\[
Q^*(t) = Q(t) + \frac{1}{\epsilon} D x h(x, t),
\]
\[
h^*(y, t) = h(x(t) + y, t) - h(x(t) - J D x h(x(t), t) y).
\]

By Lemmas 3.4 and 3.5, we have
\[
\| Q^* \|_{z_0, \rho, \varpi} \leq \| Q \|_{z_0, \rho} + \frac{1}{\epsilon} K \| x \|_{z_0, \rho, \varpi}
\]
\[
\leq \| Q \|_{z_0, \rho} + c K \frac{\Gamma(\varpi)}{\alpha} \| g \|_{z_0, \rho}.
\]

For the estimation of \( \| g^* \|_{z_0, \rho, \varpi}, \) by Lemmas 3.4 and 3.5, we have
\[
\| g^* \|_{z_0, \rho, \varpi} \leq c \frac{K}{2 \epsilon^2} \| x \|^2_{z_0, \rho, \varpi} + \frac{1}{\epsilon} \| Q \|_{z_0, \rho, \varpi}
\]
\[
\leq c \frac{\Gamma(\varpi)}{\alpha} \| Q \|_{z_0, \rho} \| g \|_{z_0, \rho} + c K \left( \frac{\Gamma(\varpi)}{\alpha} \right)^2 \| g \|^2_{z_0, \rho}.
\]

**Lemma 3.8** Let \( \{ \delta_m \} \) be a sequence of real positive numbers such that
\[
\delta_{m+1} \leq \left( \frac{\varpi}{\gamma} \right)^{2r} \delta_m^2
\]
for all \( m \geq 0, \) where \( \varpi > 0 \) and \( 1 < r < 2. \) Then
\[
\delta_m \leq \left( \frac{\varpi}{\gamma} \right)^{2r} \delta_0^{2m}.
\]

For the proof, see [5].
Lemma 3.9 Let \( f : [-\varepsilon, \varepsilon] \rightarrow \mathbb{C} \) be Lipschitz from above (with constant \( C_f \)) and from below (with constant \( c_f \)), that is,

\[ |f(u) - f(v)| \leq C_f |u - v|, \quad |f(u) - f(v)| \geq c_f |u - v|. \]

Let \( g : [-\varepsilon, \varepsilon] \rightarrow \mathbb{C} \) be another Lipschitz from above (with constant \( \delta < c_f \)), that is,

\[ |g(u) - g(v)| \leq \delta |u - v|. \]

Then \( h = f + g \) is a Lipschitz function from above (with constant \( C_f + \delta \)) and from below (with constant \( c_f - \delta \))

\[ |h(u) - h(v)| \leq (C_f + \delta) |u - v|, \quad |h(u) - h(v)| \geq (c_f - \delta) |u - v|. \]

The proof is elementary.

Lemma 3.10 Suppose that \( B_1 \) has the eigenvalues \( \lambda_1^1, \lambda_1^2, \ldots, \lambda_2^{2N} \) which satisfy \( |\lambda_1^1| > 2\nu \), \( |\lambda_1^j - \lambda_1^1| > 2\nu \), and \( \nu > 0 \) with \( s \neq j \). Suppose that \( A_0(\varepsilon) \) satisfies \( \|A_0 - B_1\| < \varepsilon \) seen in Lemma 3.3 and \( A_0(\varepsilon) \) relies on \( \varepsilon \) with constant \( L_{A_0} \) in a Lipschitz way. Suppose that \( B(\varepsilon) \) is the transformation that diagonalizes \( A_0(\varepsilon) \) (as in Lemma 3.3). Then there exist constants \( C_1, C_2 > 0 \) such that

\[
\left\| B(\varepsilon_1) - B(\varepsilon_2) \right\| \leq C_1 L_{A_0} |\varepsilon_1 - \varepsilon_2|,
\]

\[
\left\| \lambda_j(\varepsilon_1) - \lambda_j(\varepsilon_2) \right\| \leq C_2 L_{A_0} |\varepsilon_1 - \varepsilon_2|,
\]

where \( \lambda_j(\varepsilon) \) for all \( 1 \leq j \leq 2N \) denote the eigenvalues of \( A_0(\varepsilon) \).

Lemma 3.11 Let \( \{a_m\}_m \) be a sequence of positive real numbers which satisfy \( a_m \in [0, 1] \), \( \prod_{m=0}^{\infty} a_m = a \in [0, 1] \). Let \( \{b_m\}_m \) be another sequence of positive real numbers satisfying \( \prod_{m=0}^{\infty} b_m = b \in (+\infty) \). Consider the new sequence \( \{v_m\}_m \) defined by \( v_{m+1} = a_m v_m - b_m \). Then the sequence \( \{v_m\}_m \) approaches to a limit value \( v_\infty \) which satisfies \( v_\infty \geq av_0 - b \).

For the proof of Lemmas 3.10 and 3.11, see [5].

4 The first KAM step

Let \( A_0 = JA \), \( Q_0(t) = JQ(t) \) be Hamiltonian matrices. First of all, for equation (1), the possible multiple eigenvalues of \( A_0 \) are changed into distinct eigenvalues and the coefficient \( \varepsilon \) becomes \( \varepsilon^2 \) in \( Q_0(t) \) and \( g(t) \). In the following, to simplify notations, \( c > 0 \) denotes the different constants. Then the Hamiltonian system (1) can be rewritten as follows:

\[
\frac{dx}{dt} = [A_0 + \varepsilon Q_0(t)]x + \varepsilon g(t) + h(x, t),
\]

where \( x \in B_0(0) \), \( Q_0 \) and \( g \) are analytic almost-periodic on \( D_\rho \), and \( h \) is analytic almost-periodic on \( \Delta_{b, \rho} \) with spatial structure \( (\tau, [\cdot]) \). By using the symplectic transformation \( x = \)
\( x_0 + y, \) where \( x_0 \) satisfies \( \frac{dx_0}{dt} = A_0 x_0 + \varepsilon g(t) \) on \( D_{\rho - \rho} \), then system (18) becomes

\[
\frac{dy}{dt} = [A_0 + \varepsilon Q^*(t)] y + \varepsilon^2 g^*(t) + h^*(y, t),
\]

where

\[
Q^* = Q_0(t) + \frac{1}{\varepsilon} D_x h(x_0, t),
\]

\[
g^*(t) = \frac{1}{\varepsilon} h(x_0, t) + \frac{1}{\varepsilon} Q_0(t) x_0(t),
\]

\[
h^* = h(x_0, y, t) - h(x_0, t) - JD_x h(x_0, t) y.
\]

By using equation (8) and Lemma 3.4, we have

\[
\|x_0\|_{L^2_{\rho - \rho}} \leq c \varepsilon \frac{\Gamma(\overline{z}) \Gamma(\overline{\rho})}{\alpha_0} \|g\|_{L^2_{\rho - \rho}}.
\]

By defining the average of \( Q^*(t) \) as \( \overline{Q} \), equation (19) can be rewritten as follows:

\[
\frac{dy}{dt} = [A_1 + \varepsilon \overline{Q}(t)] y + \varepsilon^2 \overline{g}(t) + \overline{h}(y, t),
\]

where \( A_1 = A_0 + \varepsilon Q^* \), \( Q^*(t) = \overline{Q}(t) + \overline{Q} \), \( \overline{g} = g^* \), and \( \overline{h} = h^* \). By using the conditions of Theorem 2.1, \( A_1 \) has \( 2N \) different eigenvalues \( \lambda_1, \lambda_2, \ldots, \lambda_{2N} \) which satisfy \( |\lambda_k^1(\varepsilon) - \lambda_k^2(\varepsilon)| \geq 2\eta \varepsilon \). Now, using the symplectic change of variables \( y = e^{P_0(t)} x_1 \), system (21) is transformed into the system

\[
\frac{dx_1}{dt} = \left[ e^{-P_0(A_1 + \varepsilon \overline{Q} - \varepsilon P_0)} e^{P_0} + e^{-P_0} \left( \varepsilon \dot{P}_0 e^{P_0(t)} - \frac{d}{dt} e^{P_0(t)} \right) \right] x_1
\]

\[
+ e^{-P_0} \varepsilon^2 \overline{g}(t) + e^{-P_0} \overline{h}(e^{P_0(t)} x_1, t),
\]

where \( x \in B_b(0) \). By series expansion, we can denote

\[
e^{\varepsilon P_0} = I + \varepsilon P_0 + W, \quad e^{-\varepsilon P_0} = I - \varepsilon P_0 + \tilde{W},
\]

where

\[
W = \frac{(\varepsilon P_0)^2}{2!} + \frac{(\varepsilon P_0)^3}{3!} + \cdots,
\]

\[
\tilde{W} = \frac{(\varepsilon P_0)^2}{2!} - \frac{(\varepsilon P_0)^3}{3!} + \cdots.
\]

Then the Hamiltonian system (22) can be rewritten as follows:

\[
\frac{dx_1}{dt} = (A_1 + \varepsilon \overline{Q} - \varepsilon \dot{P}_0 + \varepsilon A_1 P_0 - \varepsilon P_0 A_1 + \varepsilon^2 \overline{Q}_1) x_1
\]

\[
+ e^{-\varepsilon P_0} \varepsilon^2 \overline{g}(t) + e^{-\varepsilon P_0} \overline{h}(e^{P_0(t)} x_1, t),
\]
where

\[ Q_1 = -P_0(\tilde{Q} - \tilde{P}_0) + (\tilde{Q} - \tilde{P}_0)P_0 - P_0(A_1 + \varepsilon \tilde{Q} - \varepsilon \tilde{P}_0)P_0 \\
+ (I - \varepsilon P_0)(A_1 + \varepsilon \tilde{Q} - \varepsilon \tilde{P}_0)W' + \tilde{W}'(A_1 + \varepsilon \tilde{Q} - \varepsilon \tilde{P}_0)e^{\varepsilon P_0} \\
+ \frac{1}{\varepsilon^2} e^{-\varepsilon P_0} \left( e^{\varepsilon P_0} - \frac{d}{dt} e^{\varepsilon P_0(t)} \right). \]

We would like to have that

\[ \tilde{Q} - \tilde{P}_0 + A_1 P_0 - P_0 A_1 = 0, \]

which is equivalent to

\[ \dot{\tilde{P}}_0 = A_1 P_0 - P_0 A_1 + \tilde{Q}. \tag{24} \]

Since \( A_0 \), \( Q^*(t) \), and \( \tilde{Q}^* \) are Hamiltonian matrices, therefore \( A_1 = A_0 + \varepsilon \tilde{Q}^* \) and \( \tilde{Q}(t) = Q^*(t) - \tilde{Q}^* \) are also Hamiltonian matrices. Using Lemma 3.6, if

\[ |\lambda_s^1 - \lambda_j^1 - \sqrt{-1}(k, \omega)| \geq \frac{\alpha_1}{\Delta^4(|k|)\Delta^4(|k|)}, \quad s \neq j, 0 \leq s, j \leq 2N \tag{25} \]

for all \( k \in \mathbb{Z}^N \setminus \{0\} \), \( \alpha_1 = \frac{a_2}{2} \), then for equation (24), a unique almost-periodic Hamiltonian matrix \( \tilde{P}_0 = \sum P_{0A} \) exists with the same spatial structure \((\tau, [\cdot])\) and the same frequencies as \( \tilde{Q}(t) \) on a smaller domain \( D_{\rho, \tau} \), which satisfies \( \tilde{P}_0 = 0 \) and

\[ \|P_0\|_{\mathcal{B}^{z,x}_\rho} \leq c \frac{\Gamma(\varepsilon)\Gamma(\gamma)}{\alpha_0} \|Q^*\|_{\mathcal{B}^{z,x}_\rho}. \tag{26} \]

Therefore, by equation (24), the Hamiltonian system (23) can be rewritten as follows:

\[ \frac{dx_1}{dt} = \left[A_1 + \varepsilon^2 Q_1(t)\right]x_1 + \varepsilon^2 g_1(t) + h_1(x_1, t), \tag{27} \]

where \( g_1(t) = e^{-\varepsilon P_0}g(t), h_1(x_1, t) = e^{-\varepsilon P_0}h(e^{\varepsilon P_0(t)}x_1, t) \), and

\[ Q_1 = -P_0(P_0 A_1 - A_1 P_0) + (P_0 A_1 - A_1 P_0)P_0 - P_0 (A_1 + \varepsilon (P_0 A_1 - A_1 P_0))P_0 \\
+ (I - \varepsilon P_0)(A_1 + \varepsilon (P_0 A_1 - A_1 P_0))W + \tilde{W}'(A_1 + \varepsilon (P_0 A_1 - A_1 P_0))e^{\varepsilon P_0} \\
+ \frac{1}{\varepsilon^2} e^{-\varepsilon P_0} \left( e^{\varepsilon P_0} - \frac{d}{dt} e^{\varepsilon P_0(t)} \right). \]

Hence, the symplectic transformation is \( T_0 x_1 = x_0 + e^{\varepsilon P_0}x_1 = \varphi_0(t, \varepsilon) + \psi_0(t, \varepsilon)x_1 \). If \( \|e^{\varepsilon P_0}\|_{\mathcal{B}^{z,x}_\rho} \leq \frac{1}{2} \), then, by equations (20) and (26), we have

\[ \|\varphi_0\|_{\mathcal{B}^{z,x}_\rho} \leq c e \frac{\Gamma(\varepsilon)\Gamma(\gamma)}{\alpha_0} \|g\|_{\mathcal{B}^{z,x}_\rho}, \tag{28} \]

\[ \|\psi_0 - I\|_{\mathcal{B}^{z,x}_\rho} \leq c e \frac{\Gamma(\varepsilon)\Gamma(\gamma)}{\alpha_0} \|Q^*\|_{\mathcal{B}^{z,x}_\rho}. \tag{29} \]
Thus, under the symplectic change of variables \( x = T_0 x_1 \), the Hamiltonian system (18) becomes Hamiltonian system (27). This completes the first KAM step.

5 Proof of the main result

5.1 The proof of Theorem 2.1

Now we will consider the standard iteration step, the proof of which is almost similar to the first KAM step. In the first step, we proved that \( A_1 \) has 2N different eigenvalues and \( \varepsilon^2 Q_1(t) \) and \( \varepsilon^2 \tilde{Q}_1(t) \) are smaller perturbations. Now the KAM method will be used to prove Theorem 2.1 and we will use a similar process as that in [5] and [8]. For simplification of structure, \( \forall \) becomes Hamiltonian system (27). This completes the first KAM step. In the first step, we proved that

\[
\| x_m \|_{z_m, \rho_m, \eta} \leq c \varepsilon^{2m} \frac{\Gamma(z_m) \Gamma(p_m)}{\alpha_m} \| g_m \|_{z_m, \rho_m},
\]

where \( 0 < z_m < z_0, 0 < \rho_m < \rho_0, \) and \( c > 0 \) is a constant. By defining the average of \( Q_m^* (t) \) as \( \bar{Q}_m^* \), equation (31) can be rewritten as follows:

\[
\frac{dy}{dt} = \left[ A_{m+1} + \varepsilon^{2m} \bar{Q}_m(t) \right] y + \varepsilon^{2m+1} \bar{g}_m(t) + \bar{h}_m(y,t),
\]

where \( A_{m+1} = A_m + \varepsilon \bar{Q}_m, Q_m^* (t) = \bar{Q}_m(t) + \bar{Q}_m^* , \bar{g}_m = g_m^*, \) and \( \bar{h}_m = h_m^* \).
Now consider $\lambda_{k_1}^{m+1}, \ldots, \lambda_{k_2}^{m+1}$ to be the different eigenvalues of $A_{m+1}$ which satisfy $|\lambda_{k_1}^{m+1} - \lambda_{k_2}^{m+1}| \geq 2\eta\epsilon > 0$, $k_1 \neq k_2$.

By applying the symplectic transformation $y = e^{-\epsilon^m P_m(t)} x_{m+1}$, system (33) is changed into

$$\frac{dx_{m+1}}{dt} = \left[ e^{-\epsilon^m P_m} (A_{m+1} + \epsilon e^{-\epsilon^m P_m} \tilde{Q}_m - \epsilon e^{-\epsilon^m P_m} \tilde{P}_m) e^{-\epsilon^m P_m} \right] x_{m+1}$$

$$+ e^{-\epsilon^m P_m} \left( e^{-\epsilon^m P_m} e^{\epsilon^m P_m(t)} - \frac{d}{dt} e^{-\epsilon^m P_m(t)} \right) x_{m+1}$$

$$+ e^{-\epsilon^m P_m} e^{\epsilon^m P_m(t)} \tilde{g}_m(t) + e^{-\epsilon^m P_m} \tilde{h}_m(t),$$

(34)

where $x_{m+1} \in B_{b_{m+1}}(0)$. By series expansion, we can denote

$$e^{-\epsilon^m P_m} = I + \epsilon e^{-\epsilon^m P_m} + \mathcal{W}_m, \quad e^{-\epsilon^m P_m} = I - \epsilon e^{-\epsilon^m P_m} + \mathcal{W}_m,$$

where

$$\mathcal{W}_m = \frac{(\epsilon e^{-\epsilon^m P_m})^2}{2!} + \frac{(\epsilon e^{-\epsilon^m P_m})^3}{3!} + \cdots, \quad \tilde{\mathcal{W}}_m = \frac{(\epsilon e^{-\epsilon^m P_m})^2}{2!} - \frac{(\epsilon e^{-\epsilon^m P_m})^3}{3!} + \cdots.$$

Then system (34) can be rewritten as follows:

$$\frac{dx_{m+1}}{dt} = \left[ A_{m+1} + \epsilon e^{-\epsilon^m P_m} \tilde{Q}_m - \epsilon e^{-\epsilon^m P_m} \tilde{P}_m + \epsilon e^{-\epsilon^m P_m} A_{m+1} P_m - \epsilon e^{-\epsilon^m P_m} P_m A_{m+1} + \epsilon e^{-\epsilon^m P_m} Q_{m+1}(t) \right] x_{m+1}$$

$$+ e^{-\epsilon^m P_m} e^{\epsilon^m P_m(t)} \tilde{g}_m(t) + e^{-\epsilon^m P_m} \tilde{h}_m(t),$$

(35)

where

$$Q_{m+1}(t) = -P_m(\tilde{Q}_m - \tilde{P}_m) + (\tilde{Q}_m - \tilde{P}_m) P_m - P_m (A_{m+1} + \epsilon e^{-\epsilon^m P_m} (\tilde{Q}_m - \tilde{P}_m) P_m$$

$$+ (I - \epsilon e^{-\epsilon^m P_m}) (A_{m+1} + \epsilon e^{-\epsilon^m P_m} (\tilde{Q}_m - \tilde{P}_m)) \mathcal{W}_m \frac{\epsilon}{e^{-\epsilon^m P_m}}$$

$$+ \frac{\tilde{\mathcal{W}}_m}{\epsilon e^{-\epsilon^m P_m}} (A_{m+1} + \epsilon e^{-\epsilon^m P_m} (\tilde{Q}_m - \tilde{P}_m)) e^{-\epsilon^m P_m}$$

$$+ \frac{1}{\epsilon e^{-\epsilon^m P_m}} e^{-\epsilon^m P_m} \left( e^{-\epsilon^m P_m} e^{\epsilon^m P_m(t)} - \frac{d}{dt} e^{-\epsilon^m P_m} \right).$$

We would like to have

$$\tilde{Q}_m - \tilde{P}_m + A_{m+1} P_m - P_m A_{m+1} = 0.$$

This can be rewritten as

$$\dot{P}_m = A_{m+1} P_m - P_m A_{m+1} + \tilde{Q}_m.$$

(36)

Since $A_m$, $Q^+_m(t)$, and $\tilde{Q}_m^+$ are Hamiltonian, therefore $A_{m+1}$ and $\tilde{Q}_m(t)$ are Hamiltonian.

By Lemma 3.6, if

$$|\lambda_{k_1}^{m+1} - \lambda_{k_2}^{m+1} - \sqrt{-1}(k, \omega)| \geq \frac{\alpha_m}{\Delta^4(|k|) \Delta^4(|\omega|)}, \quad k \in \mathbb{Z}^N \setminus \{0\}$$
and for different eigenvalues $\lambda_{m}^{i}$, $\ldots$, $\lambda_{m}^{j}$ of $A_{m+1}$ with $|\lambda_{s}^{m+1} - \lambda_{j}^{m+1}| \geq \eta \epsilon$, $s \neq j$, $0 \leq s, j \leq 2N$, then for equation (36), there exists a unique almost-periodic matrix $P_{m}(t) = \sum_{\lambda \in \mathcal{E}} P_{m}(t)$ on $D_{m} \sim \mathbb{P}_{m}$ with frequencies $\omega$ and spatial structure $(r, \left[\cdot\right])$, which satisfies

$$
\|P_{m}\|_{m+1, \omega \cdot m - \mathbb{P}_{m}} \leq c e^{\frac{\Gamma(z)}{\alpha}} \|Q_{m}\|_{m, \omega \cdot m}.
$$

Then the Hamiltonian system (35) becomes

$$
\frac{dx_{m+1}}{dt} = [A_{m+1} + \epsilon^{2m+1} Q_{m+1}(t)]x_{m+1} + \epsilon^{2m+1} g_{m+1}(t) + h_{m+1}(x_{m+1}, t),
$$

where $g_{m+1}(t) = e^{-e^{2m} p_{m} \bar{Q}_{m}}(t)$, $h_{m+1}(x_{m+1}, t) = e^{-e^{2m} p_{m} \bar{h}_{m}}(e^{e^{2m} p_{m}(t)} x_{m+1}, t)$, and by using $\bar{Q}_{m} - \bar{p}_{m} = P_{m} A_{m+1} - A_{m+1} P_{m}$, we have

$$
Q_{m+1}(t) = -P_{m}(P_{m} A_{m+1} - A_{m+1} P_{m}) + (P_{m} A_{m+1} - A_{m+1} P_{m}) P_{m}
$$

$$
+ (I - \epsilon^{2m} P_{m}) (A_{m+1} + \epsilon^{2m} (P_{m} A_{m+1} - A_{m+1} P_{m})) W_{m}
$$

$$
+ \frac{\bar{W}_{m}}{\epsilon^{2m}} (A_{m+1} + \epsilon^{2m} (P_{m} A_{m+1} - A_{m+1} P_{m}) e^{2m} p_{m}
$$

$$
+ \frac{1}{\epsilon^{2m}} e^{-e^{2m} p_{m}} \left( e^{2m} \bar{P}_{m} e^{2m} p_{m} - \frac{d}{dt} e^{2m} p_{m}(t) \right).
$$

Thus, the symplectic transformation is $T_{m} x_{m+1} = \xi_{m} + \epsilon^{2m} p_{m} x_{m+1} = \phi_{m}(t) + \psi_{m}(t) x_{m+1}$. If $\|e^{2m} p_{m}\|_{m+1, \omega \cdot m - \mathbb{P}_{m}} \leq \frac{1}{\epsilon^{2m}}$, then by equations (32) and (37), we have

$$
\|\psi_{m} \|_{m+1, \omega \cdot m - \mathbb{P}_{m}} \leq c e^{\frac{\Gamma(z)}{\alpha}} \|g_{m} \|_{m, \omega \cdot m},
$$

$$
\|\psi_{m} - I \|_{m+1, \omega \cdot m - \mathbb{P}_{m}} \leq c e^{\frac{\Gamma(z)}{\alpha}} \|Q_{m} \|_{m, \omega \cdot m}.
$$

So, using the symplectic change of variables $x_{m} = T_{m} x_{m+1}$, system (30) is transformed into system (38).

### 5.2 Iteration

Now we estimate the bounds of $\|g_{m+1}\|_{m+1}$ and $\|Q_{m+1}\|_{m+1}$ as $m \to \infty$. For the $m$th step, we choose

$$
\alpha_{m} = \alpha_{m-1} \frac{\alpha_{0}}{2^{m}}, \quad \beta_{m+1} = \frac{\beta_{m} - \|z_{m}\|_{m}}{e^{2m} \|P_{m+1}\|_{m+1}}, \quad \|m \| = \|m \|_{2m, \omega \cdot m}.
$$

Also, suppose that $z_{v} \downarrow 0$ and $\bar{P}_{v} \downarrow 0$ satisfy $\sum_{v=0}^{\infty} z_{v} = \frac{1}{2} z$ and $\sum_{v=0}^{\infty} \bar{P}_{v} = \frac{1}{2} \bar{P}$. And set $z_{m} = z - \sum_{v=0}^{m-1} z_{v}, \rho_{m} = \rho - \sum_{v=0}^{m-1} \bar{P}_{v}$. Assume that

$$
\varphi(\rho) = \inf_{\rho_{1}, \rho_{2}, \ldots, \rho_{m}} \prod_{v=1}^{m} [\Gamma(\rho_{v})]^{2^{v-1}},
$$

Afzaletal. (2018) 1808:199
then
\[
\varphi\left(\frac{1}{2}z\right) = \prod_{v=1}^{\infty} \left[ 1/\Gamma(v) \right]^{2^{v-1}}.
\]

and
\[
\varphi\left(\frac{1}{2}\rho\right) = \prod_{v=1}^{\infty} \left[ 1/\Gamma(v) \right]^{2^{v-1}}.
\]

If \(\|e^{2m}P_m\|_{m+1} \leq \frac{1}{2}\), we have
\[
b_{m+1} \geq \frac{b_m - \|x_m\|_m}{1 + 2e^{2m} \|P_m\|_{m+1}}.
\] (42)

By using Lemma 3.11, equation (42), and for sufficiently small \(\varepsilon\), we obtain \(b_\infty = \lim_{m \to \infty} b_m \geq \sigma\) with constant \(\sigma > 0\). By Lemma 3.7, we obtain
\[
\|Q_m\|_{m+1} \leq \|Q_m\|_m + cK_{m} \frac{\Gamma(z_{m+1}) \Gamma(\rho_{m+1})}{\alpha_m} \|g_m\|_m.
\] (43)

Therefore, by equations (37) and (43), we have
\[
\|P_m\|_{m+1} \leq cK_{m} \frac{(\Gamma(z_{m+1}) \Gamma(\rho_{m+1}))^2}{\alpha_m \alpha_{m+1}} \left( \|Q_m\|_m + \|g_m\|_m \right).
\] (44)

Set
\[
c_1 = \max\left\{ c_1, \frac{8c}{\alpha} \right\}, \quad c_m = \left[ (m+1)^{2^{-z_{m+1}}} m^{2^{-z}} \cdots 2^{z-2} \cdot 1^{z-1} \right]^{2}
\]

\[
\Phi_m(z) = \prod_{v=1}^{m+1} \left[ 1/\Gamma(v) \right]^{2^{v}}, \quad \Phi_m(\rho) = \prod_{v=1}^{m+1} \left[ 1/\Gamma(v) \right]^{2^{v}}.
\]

From [9], \(c_m, \Phi_m(z), \Phi_m(\rho)\) are all convergent when \(m\) goes to infinity. Consider
\[
\mathcal{M}_1 = \max\left\{ 1, \sup_m (c_1 c_m \Phi_m(z) \Phi_m(\rho)) \right\} \|Q(t)\|_{z,\rho},
\]
\[
\mathcal{M}_2 = \max\left\{ 1, \sup_m (c_1 c_m \Phi_m(z) \Phi_m(\rho)) \right\} \|g(t)\|_{z,\rho},
\]

and set
\[
\mathcal{M} = \max\{\mathcal{M}_1, \mathcal{M}_2\}.
\]

Firstly, we calculate \(\|g_{m+1}\|_{m+1}\). By Lemma 3.7, we have
\[
\|g_{m+1}\|_{m+1} \leq c \frac{\Gamma(z_{m+1}) \Gamma(\rho_{m+1})}{\alpha_m} \left( \|Q_m\|_m + cK_{m} \frac{\Gamma(z_{m+1}) \Gamma(\rho_{m+1})}{\alpha_m} \|g_m\|_m \right) \|g_m\|_m.
\] (45)

Now we estimate \(\|Q_{m+1}\|_{m+1}\).
If \( \|e^{2m} P_m\|_{m+1} \leq \frac{1}{2} \), we have

\[
\left\| e^{2m} \right\|_{m+1} \leq 1 + \|e^{2m} P_m\| + \frac{\|e^{2m} P_m\|^2}{2!} + \cdots \leq 2.
\]

Moreover, we have that

\[
\frac{d}{dt} e^{2m} P_m = \frac{d}{dt} e^{2m} P_m(t)
\]

\[
= \left( e^{2m} P_m e^{-2m} P_m + e^{2m} P_m \frac{(e^{2m} P_m)^2}{2!} + e^{2m} P_m \frac{(e^{2m} P_m)^3}{3!} + \cdots \right)
\]

\[
- \frac{d}{dt} \left( e^{2m} P_m \right)^n \leq 4 \left[ \|e^{2m} P_m\|_{m+1} \|e^{2m} P_m\|^n \right].
\]

By equations (36) and (43), we have

\[
\left\| e^{2m} P_m e^{2m} P_m - \frac{d}{dt} e^{2m} P_m(t) \right\|_{m+1} \leq 4 \|e^{2m} P_m\|_{m+1} \|e^{2m} P_m\|_{m+1}.
\]

If \( \|e^{2m} P_m\|_{m+1} \leq \frac{1}{2} \), by

\[
\left\| \frac{d}{dt} \left( e^{2m} P_m \right)^n \right\| \leq n \left\| e^{2m} P_m \right\| e^{2m} P_m \left. \right|^n, \quad \text{for } n \in \mathbb{Z},
\]

we obtain that

\[
\left\| e^{2m} P_m e^{2m} P_m - \frac{d}{dt} e^{2m} P_m(t) \right\|_{m+1} \leq 4 \left\| e^{2m} P_m \right\|_{m+1} \left\| e^{2m} P_m \right\|_{m+1}.
\]

By equations (36) and (43), we have

\[
\left\| e^{2m} P_m e^{2m} P_m - \frac{d}{dt} e^{2m} P_m(t) \right\|_{m+1} \leq 4 \left\| e^{2m} P_m \right\|_{m+1} \left\| e^{2m} P_m \right\|_{m+1}.
\]

Also, if \( \|e^{2m} P_m\|_{m+1} \leq \frac{1}{2} \), we have

\[
\left\| W_m \right\|_{m+1}, \left\| \tilde{W}_m \right\|_{m+1} \leq 2 \left\| e^{2m} P_m \right\|_{m+1}.
\]

So, by equations (40), (46), and (47), we have

\[
\left\| Q_{m+1} \right\|_{m+1} \leq cK_m \left( \|P_m\|_{m+1} \|Q_m\|_m \right)
\]

\[
+ \|P_m\|_{m+1} \|Q_m\|_m + \|P_m\|_{m+1} \|g_m\|_m).
\]

Then, by using equation (43), the above equation can be written as follows:

\[
\left\| Q_{m+1} \right\|_{m+1} \leq cK_m \left( \left( \|P_m\|_{m+1} \|Q_m\|_m \right)^2 \right) \left( \|Q_m\|_m + \|g_m\|_m \right).
\]

\[
\left( \|Q_m\|_m + \|Q_m\|_m + \|g_m\|_m \right).
\]
For the estimate of $\|Q_m\|_m$ and $\|g_m\|_m$, we define

$$\delta_m = \max \{\|Q_m\|_m, \|g_m\|_m\}.$$ 

By equations (45) and (48), we have that

$$\delta_{m+1} \leq c K_m \left( \frac{\Gamma^2 (\bar{\rho}_{m+1}) \Gamma^2 (\bar{\omega}_{m+1})}{\alpha_m^2 \alpha_{m+1}^2} \right) \delta_m,$$  

(49)

where $c > 0$ is a constant depending on $\rho$, $\omega$, and $M$.

If $\|\varepsilon^2 P_t\| \leq \frac{1}{4}$ for $l = 0, 1, 2, \ldots, m - 1$, then we have $K_m \leq \left( \frac{\alpha}{2} \right)^m$ (as given below). It is immediate to check that we can find $\bar{\gamma} > 0$ such that

$$\frac{cK_m^2}{\alpha_m^2 \alpha_{m+1}^2} \left( \Gamma (\bar{\rho}_{m+1}) \Gamma (\bar{\omega}_{m+1}) \right) \leq (\bar{\gamma} r^m) \frac{\|Q_m\|_m}{\|g_m\|_m},$$

where $1 < r < 2$.

Using Lemma 3.8, we have $\delta_m \leq M^{2m}$, where $M = (\bar{\gamma} r^m)^{\frac{1}{2m}}$. Thus, we have

$$\|Q_m\|_m \leq M^{2m}, \quad \|g_m\|_m \leq M^{2m}.$$  

(50)

If $0 < \varepsilon M < 1$, then we obtain

$$\lim_{m \to \infty} \varepsilon^{2m} \|Q_m\|_m = 0, \quad \lim_{m \to \infty} \varepsilon^{2m} \|g_m\|_m = 0.$$  

(51)

Now, we bound $\|A_m\|$. By (43), we have

$$\|A_m - A_m\| \leq \left( \varepsilon^{2m} \right) \left( \frac{\|Q_m\|_m + c K_m \Gamma^2 (\bar{\omega}_{m+1}) \Gamma^2 (\bar{\omega}_{m+1})}{\alpha_m} \|g_m\|_m \right).$$  

(52)

By $c K_m \left( \frac{\Gamma^2 (\bar{\omega}_{m+1}) \Gamma^2 (\bar{\omega}_{m+1})}{\alpha_m} \right) \leq M^{2m}$, with suitable constant $M_1 > 0$ and (50), if $0 < M_2 < 1$, then $m \to \infty$, $\|A_m - A_m\| \to 0$. Hence, $A_m$ is convergent, as $m \to \infty$. Suppose

$$\lim_{m \to \infty} A_m = A_*.$$  

(53)

Also, by (40), (41), (43), and (50), we have

$$\lim_{m \to \infty} \|\psi_m\|_m = 0, \quad \lim_{m \to \infty} \|\psi_m - I\|_{m+1} = 0.$$  

(54)

Let $D_{z,\Delta,\frac{1}{2} \rho} = \bigcap_{m=0}^{\infty} D_{z,\Delta,\frac{1}{2} \rho, \omega_m}$. By equations (28), (29), (40), and (41), and by the conditions of Theorem 2.1, suppose $T^m = T_0 \circ T_1 \circ \cdots \circ T_{m-1}$. And the convergence of $T^m$ is easy to prove on $D_{z,\Delta,\frac{1}{2} \rho}$ as $m \to \infty$. Let $T^m \to T$ on $D_{z,\Delta,\frac{1}{2} \rho}$ as $m \to \infty$. To bound $\|P_m\|_{m+1}$. For (44), it is not difficult to choose $c K_m \left( \frac{\Gamma^2 (\bar{\rho}_{m+1}) \Gamma^2 (\bar{\omega}_{m+1})}{\alpha_m^2 \alpha_{m+1}^2} \right) \leq M^{2m}$ with suitable constant $M_2 > 0$. So, by (50), if $0 < M_2 M < 1$, we have

$$\lim_{m \to \infty} \varepsilon^{2m} \|P_m\|_m = 0.$$  

This allows us to have the condition $\varepsilon^{2m} \|P_m\|_m \leq \frac{1}{2}$ without reducing the value of $\varepsilon$ at each step. Now we will show that $K_m$ is convergent for $m \to \infty$. By (38), we have

$$\|D_{z,\Delta,\frac{1}{2} \rho, \omega_m} h_m \|_m \leq \left( 1 + 2 \frac{\varepsilon^{2m} \|P_m\|_m}{\|g_m\|_m} \right) K_m.$$  

(55)
So, if $\varepsilon^2 \| P_m \|_{m+1} \leq \frac{1}{4}$, we already have $K_m \leq (\frac{3}{2})^m K$. By the inequality $\frac{1}{1-x} \leq 1 + 2x$, if $\frac{1}{4} \leq \varepsilon \leq \frac{1}{2}$ and (55), we obtain

$$K_{m+1} \leq (1 + 4\varepsilon^2 \| P_m \|_{m+1})^3 K_m.$$  

(56)

Using the convergent bound of $\| P_m \|_{m+1}$ and since $K_m \leq (\frac{9}{2})^m K$, then by (56) it is easy to obtain that the value of $K_m$ is convergent for $m \to \infty$. Suppose

$$\lim_{m \to \infty} K_m = K_*.$$  

(57)

Thus, $\lim_{m \to \infty} h_m = h_*(y, t) = O(y^3)$ as $y \to 0$.

Hence, using the symplectic change of variables $x = Ty = \psi(t) + \psi(t)y$ on $D_{\frac{1}{2}x, \Delta b_{\frac{1}{2}y}}$, system (1) is changed into the Hamiltonian system (10).

5.3 Measure estimate

Now, for small enough $\varepsilon_0$, we will prove that the non-resonant conditions

$$|\lambda^m_s - \sqrt{-1}(k, \omega)| \geq \frac{\alpha_m}{\Delta^4(|k|)\Delta^4(|\lambda|)}$$

and

$$|\lambda^m_s - \lambda^m_j - \sqrt{-1}(k, \omega)| \geq \frac{\alpha_m}{\Delta^4(|k|)\Delta^4(|\lambda|)}$$

for most $\varepsilon \in (0, \varepsilon_0)$ hold, where $1 \leq s, j \leq 2N$, $m = 0, 1, 2, \ldots$, $k \in \mathbb{Z}^N \setminus \{0\}$, and $\Delta(t)$ is an approximation function.

Consider the Lipschitz constants from below and above of $f(\varepsilon)$ are $l(f(\varepsilon))$ and $L(f(\varepsilon))$, respectively. For any loss of generality, we can suppose that $\lambda^m_s - \lambda^m_j$ are pure imaginary numbers. So, we suppose

$$|\lambda^m_s - \lambda^m_j - \sqrt{-1}(k, \omega)| \geq \frac{\alpha_m}{\Delta^4(|k|)\Delta^4(|\lambda|)},$$

(58)

where $\lambda^m_s(\varepsilon) - \lambda^m_j(\varepsilon)$ satisfies $l(\lambda^m_s(\varepsilon) - \lambda^m_j(\varepsilon)) \geq \eta_0 > 0$ for a constant $\eta_0$ with $s \neq j$.

Remark Assume that $A_m(\varepsilon)$ is a Lipschitz function of $\varepsilon$ and $L(A_m) - L(A_j) = O(\varepsilon)$. By using Lemmas 3.9 and 3.10, and hypothesis (3) of Theorem 2.1, it is easy to prove that the eigenvalues $\lambda^m_s$ and the differences $\lambda^m_s - \lambda^m_j$ are Lipschitz from below and above if $\varepsilon$ is small enough.

The proof of the above remark can be seen in [5].

By condition (2) of Theorem 2.1, for $m = 0$, equation (58) holds. And, by condition (2) of Theorem 2.1, we obtain that (58) also holds for $s = j$. Let

$$f(\varepsilon) = \lambda^m_s - \lambda^m_j - \sqrt{-1}(k, \omega), \quad s \neq j$$

and

$$O_{sjm}^\varepsilon = \{\varepsilon \in (0, \varepsilon_0) : |f(\varepsilon)| < \frac{\alpha_m}{\Delta^4(|k|)\Delta^4(|\lambda|)}\}.$$
such that system (30) converges for \( \varepsilon \in (0, \varepsilon_0) \) whenever \( \varepsilon_0 \) is small enough and

\[
I(\lambda^m_\varepsilon - \lambda^{m+1}_\varepsilon) \geq \eta_0. 
\]  

(59)

Since

\[
|f(\varepsilon)| \geq |\lambda_\varepsilon - \lambda_j - \sqrt{-1}(k, \omega)| - 2M\varepsilon
\geq \frac{\alpha_0}{\Delta(|k|)\Delta(|k|)} - 2M\varepsilon_0.
\]

For \( |k| \leq m, |k| \leq m, \) and if \( \frac{1}{4\Delta(|k|)\Delta(|k|)} > \frac{\alpha_0}{\eta_0} \), then

\[
|f(\varepsilon)| \geq \frac{\alpha_0}{\Delta(|k|)\Delta(|k|)} - \frac{\alpha_0}{2\Delta(m)\Delta(m)}
\geq \frac{\alpha_m}{\Delta^4(|k|)\Delta^4(|k|)}
\geq \frac{\alpha_m}{\Delta^4(|k|)\Delta^4(|k|)}
\]

and \( O^k_{sjm} = \phi \).

Let, for \( |k| \geq m, |k| \geq m, \) and if \( \frac{1}{4\Delta(|k|)\Delta(|k|)} < \frac{\alpha_0}{\eta_0} \). By equation (59), we have

\[
\text{mes}(O^k_{sjm}) < \frac{\alpha_m}{\Delta^4(|k|)\Delta^4(|k|)}\eta_0,
\]

\[
\text{mes}\left(\bigcup_{s \neq j} \bigcup_{k \in \mathbb{Z}^N \setminus \{0\}} O^k_{sjm}\right) \leq \sum_{1 \leq s < 2|d|,|k| \geq m, |k| \geq m} \text{mes}(O^k_{sjm})
\leq \frac{cd_0^2\alpha_0}{\alpha\Delta^3(m)} \sum_{k \in \mathbb{Z}^N \setminus \{0\}} \frac{1}{\Delta(|k|)\Delta(|k|)}
\leq \frac{ce_0^2}{\Delta^3(m)}.
\]

Let

\[
E_m = \left\{ \varepsilon \in (0, \varepsilon_0) : |\lambda^m_\varepsilon - \lambda^m_j - \sqrt{-1}(k, \omega)| \geq \frac{\alpha_m}{\Delta^4(|k|)\Delta^4(|k|)}, k \in \mathbb{Z}^N \setminus \{0\}, s \neq j \right\}.
\]

Then

\[
(0, \varepsilon_0) - E_m = \bigcup_{s \neq j} \bigcup_{k \in \mathbb{Z}^N \setminus \{0\}} O^k_{sjm}.
\]

Thus

\[
\text{mes}(E_m) \leq \frac{ce_0^2}{\Delta^3(m)}.
\]

Let \( E = \bigcap_{m=1}^{\infty} E_m \), then

\[
\text{mes}(0, \varepsilon_0) - E_m \leq \frac{ce_0^2}{2}.
\]
and
\[
\lim_{\varepsilon_0 \to 0} \frac{\text{mes}((0, \varepsilon_0) - E_m)}{\varepsilon_0} = 0.
\]
So, if \( \varepsilon_0 \) is sufficiently small, \( E \) is a non-empty subset of \((0, \varepsilon_0)\). Similar to the above, for sufficiently small \( \varepsilon_0 \), \( |\lambda_m - \sqrt{-1} \langle k, \omega \rangle| \geq \frac{\Delta_1}{\Delta_4(\|k\|)} \) holds for most \( \varepsilon \in (0, \varepsilon_0) \). Hence, we proved that system (1) is changed into the Hamiltonian system (10).

6 Conclusion

In this work, we discussed the reducibility of almost-periodic Hamiltonian systems and proved that the almost-periodic non-linear Hamiltonian system (1) is reduced to a constant coefficients Hamiltonian system with an equilibrium by means of an almost-periodic symplectic transformation. The result was proved for a sufficiently small parameter \( \varepsilon \) by using some non-resonant conditions, non-degeneracy conditions, the suitable hypothesis of analyticity, and KAM iterations.
