Abstract

Background We aimed to compare the demographic, clinical and laboratory characteristics between IgG4-related kidney disease (IgG4-RKD+) and extrarenal IgG4-related disease (IgG4-RKD-) in a large Chinese cohort, as well as describing the radiological and pathological features of IgG4-RKD+.

Methods We retrospectively analyzed the medical records of 450 IgG4-RD patients at Peking University People's Hospital from January 2004 to January 2020.

Results Among the 450 IgG4-RD patients, 66 were diagnosed with IgG4-RKD+. Compared with IgG4-RKD-patients, IgG4-RKD+ patients had older age at onset and at diagnosis (59 vs 54, \( P = 0.007 \); 61 vs 56, \( P = 0.002 \), respectively). Male to female ratio of IgG4-RKD+ patients is significantly higher (2.5:1 vs 1.2:1, \( P = 0.015 \)). In the IgG4-RKD+ group, the most commonly involved organs were salivary gland (54.6%), lymph nodes (47.0%) and pancreas (40.9%). More than three organs involved (OR=6.212), retroperitoneal fibrosis involvement (RPF) (OR=12.460) and low serum C3 level (OR=0.202) were risk factors for the kidney disease in IgG4-RD patients. It was found that renal function was impaired in more than 50% of IgG4-RKD+ patients. The most common imaging finding is multiple, often bilateral, hypodense lesions, followed by ureteric obstruction and hydronephrosis related to RPF, and thickening of the renal pelvic wall.

Conclusions Involvement of three or more organs, retroperitoneal fibrosis and low serum C3 level were risk factors for the kidney disease in IgG4-RD patients. These findings indicate potential differences in pathogenesis of these two phenotypes.

Background

IgG4-related disease (IgG4-RD) is a systemic fibroinflammatory immune-mediated disorder, which is characterized by high levels of serum IgG4, dense lymphoplasmacytic infiltration with IgG4-positive plasma cells in multiple organs, featured storiform fibrosis, and obliterative phlebitis [1–4].

In 2001, IgG4-RD was first described in pancreas, which was called type 1 autoimmune pancreatitis (AIP) [5]. Subsequent studies have revealed that IgG4-RD can affect any organ system. IgG4-related kidney disease (IgG4-RKD+) refers to the renal lesions in association with IgG4-RD. Previous studies have reported the kidney involvement in approximately 12–23% of total IgG4-RD patients [4, 6–8]. IgG4-RKD+ could be manifested by a variety of clinical and histological characteristics, such as tubulointerstitial nephritis (TIN), membranous glomerulonephropathy (MGN) and other infrequent glomerular lesions, pyelitis, hydronephrosis and acute renal failure resulted from retroperitoneal fibrosis (RPF) [9, 10].

To minimize the impact of irreversible renal damage resulting from the disease itself or unnecessary surgical intervention, early recognition and treatment are of pivotal importance. In this study, demographic, clinical, and laboratory disparities in the 66 IgG4-RKD+ and 384 IgG4RKD- patients were investigated. To our best knowledge, this is the largest study to compare the two phenotypes of patients...
with or without kidney involvement related to IgG4-RD. Determining the characteristics of these two phenotypes may help identify risk factors and their potential differences in pathogenesis.

**Methods**

**Patients**

From January 2004 to January 2020, four hundred and fifty IgG4-RD patients who were presented at Peking University People's Hospital with complete clinical data were enrolled in this study. Based on the 2011 comprehensive IgG4-RD diagnostic criteria [9], there were 216 (48.0%), 35 (7.8%) and 199 (44.2%) cases diagnosed with definite, probable and possible IgG4-RD, respectively (Table 1).
| Characteristics                                      | All (n = 450) | IgG4-RKD+ (n = 66) | IgG4-RKD- (n = 384) | P-value |

IgG4-RKD + vs IgG4-RKD-, **P < 0.05
Patients were screened for IgG4-RKD + in case of unexplained urinary abnormalities, renal imaging, or histology suggestive of IgG4 RKD + or if they had renal involvement with conditions known to be associated with IgG4-RD. Patients who had any definite etiology of renal impairment were excluded from the study [11, 12]. Renal pathological findings were available for 6 patients: dense lymphoplasmacytic infiltration with more than 10 infiltrating IgG4-positive plasma cells per high-power field and an IgG4/IgG plasma cell ratio of more than 40% with fibrosis. In total, there were 66 patients diagnosed with IgG4-RKD+.

Gender, age, allergic diseases, clinical manifestations, organ involvement, radiological and pathological findings were recorded. According to the criteria from the European Academy of Allergy and Clinical Immunology (EAACI), allergic disease was diagnosed by experienced specialists. This study was approved by the Medical Ethics Committee of Peking University People’s Hospital (Beijing, China).

**Laboratory Features, Imaging Examination And Histological Studies**

We recorded laboratory tests, including serum IgG4 level, serum IgE level, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), eosinophilia, serum C3, serum C4, hemoglobin (Hb), and renal function (including urine specific gravity, PH, proteinuria, urinary white blood cells, urine occult blood, urea **
nitrogen, creatinine, estimated glomerular filtration rate (eGFR), serum β2-microglobulin (β2-MG), urine N-acetyl-β-D-glucosidase (NAG), and retinol-binding protein (RBP)).

All patients underwent radiology examinations consisting of Computed Tomography (CT), or Magnetic resonance imaging (MRI), and some patients also received 18F-fluorodeoxyglucose PET-CT.

We fixed all tissue biopsy samples in formalin and embedded in paraffin, then stained them with hematoxylin and eosin (H&E) and immunocytochemistry (IHC). IHC was performed using the avidin-biotin complex-peroxidase method with monoclonal antibody to human IgG4 (Zymed, Carlsbad, CA; dilution 1:50 or 1:100 depending on staining laboratory) on sections from paraffin-embedded tissue.

The renal biopsy was examined specifically for features suggestive of IgG4-RKD+, including presence of TIN, lymphoplasmacytic infiltration, as well as tubulointerstitial presentations on light microscopy, glomerular light microscopy abnormalities, glomerular or tubular basement membrane (TBM) deposits on IF or EM. IgG4 staining was done and the number of positive plasma cells/hpf were calculated.

Statistical analysis

Using Stata software (V.15.0; Stata, College Station, TX, USA), data were analyzed by descriptive methods, with standard summary statistics including mean (S.D.), median, interquartile range (IQR), and proportions. We performed the Student’s t test for differences for continuous, normally distributed data; continuous, non-normally distributed data were analyzed by the Mann-Whitney test. Categorical variables were processed by χ² or Fisher’s exact tests. Logistic regression analysis with enter method was performed to compare the IgG4-RKD+ and IgG4-RKD- patients. Factors with P<0.2 in the univariate analysis were included in the multivariate analysis. P<0.05 was considered to be statistically significant.

Results

Demographic features

Demographic details of all the 450 IgG4-RD patients were outlined in Table 1. Among the 450 patients, there were 66 (14.7%) patients with renal involvement (IgG4-RKD+), and 384 (85.3%) patients without renal involvement (IgG4-RKD-). The comparison of demographic characteristics of IgG4-RKD+ and IgG4-RKD- patients was also indicated in Table 1. Compared with IgG4-RKD- patients, IgG4-RKD+ patients had older age at onset and older age at diagnosis (59 vs 54, P=0.007; 61 vs 56, P=0.002, respectively). Male to female ratio of IgG4-RKD+ patients is significantly higher (2.5:1 vs 1.2:1, P=0.015).

Clinical Characteristics

As shown in Table 1, there were more patients with involved organs of 3 or more in the IgG4-RKD+ group than that in the IgG4-RKD- group (84.9% vs 61.7%, P<0.001). Detailed organ involvement between IgG4-RKD+ and IgG4-RKD- groups was shown in Fig. 1. In the IgG4-RKD+ group, the most commonly involved organs were salivary gland (54.6%), lymph nodes (47.0%) and pancreas (40.9%). While in the IgG4-RKD-
group, salivary gland (67.5%) was the most commonly affected organ, followed by lacrimal gland (50.3%), and lymph nodes (45.3%). The involvement of retroperitoneal fibrosis (36.4% vs 10.9%, \( P < 0.001 \)) was more common in IgG4-RKD + patients. While in the IgG4-RKD- group, the involvement of salivary gland (54.6% vs 67.5%, \( P = 0.042 \)) was more common. More patients were significantly associated with allergic diseases in the IgG4-RKD- group than that in the IgG4-RKD + group (43.2% vs 28.8%, \( P = 0.028 \)).

**Laboratory Parameters**

Disparities in laboratory features between the IgG4-RKD + and IgG4-RKD- groups were indicated in Table 1. No significant differences were found in levels of serum CRP, IgG4 and IgE, eosinophil count, serum C3, and serum C4. Higher level of ESR was found in the IgG4-RKD + group (27.5 vs 16 for Hb, \( P = 0.015 \)). However, Hb were significantly lower in the IgG4-RKD + group (121.5 vs 135.5, \( P = 0.001 \)).

**Renal damage indexes of the IgG4-RKD+ group**

As presented in Table 2, it was found that renal function was impaired with the reduced eGFR (53%), elevated blood urea nitrogen (37.9%) and elevated serum creatine (30.3%). The median eGFR was 78.5 mL/min/1.73 m² (IQR, 58.5, 100.2). The level of serum creatinine varied from 64 to 122 umol/L at baseline. The median blood urea nitrogen was 6.9 mmol/L (IQR, 5.1, 9.2). Nineteen (28.8%) of the 66 IgG4-RKD + patients presented with proteinuria (1 + or greater on dipstick). Approximately 50% of IgG4-RKD + patients presented with urine occult blood. Positive urinary white blood cells (urinary white blood cells > 14 /ul) excluding urinary infection were detected in 17 (25.8%) patients.
Table 2  
Renal indexes in IgG4-RKD+ patients (n=66)  

| Characteristics                                      | Values                          |
|------------------------------------------------------|--------------------------------|
| Urine specific gravity, median (IQR)                 | 1.013 (1.009,1.020)            |
| Reduced gravity, n (%)                               | 3 (4.5)                        |
| PH, median (IQR)                                     | 6 (5.5,6.5)                    |
| Reduced PH, n (%)                                     | 0 (0)                          |
| Proteinuria (1+ or greater on dipstick), n (%)        | 19 (28.8)                      |
| Urine occult blood (+), n (%)                        | 32 (48.5)                      |
| Urinary white blood cells (+), n (%)                  | 17 (25.8)                      |
| Estimated GFR, mL/min/1.73 m^2                        | 78.5 (58.5,100.2)              |
| Reduced estimated GFR (ml/min/1.73m2), n (%)         | 35 (53.0)                      |
| Blood urea nitrogen (mmol/L), median (IQR)           | 6.9 (5.1,9.2)                  |
| Elevated blood urea nitrogen (mmol/L), n (%)         | 25 (37.9)                      |
| Serum creatine (umol/L), median (IQR)                | 88.5 (64,122)                  |
| Elevated serum creatine (umol/L), n (%)             | 20 (30.3)                      |

**Renal tubular function test***  

| β2-MG (ug/L), median (IQR)                           | 2282.5 (758,8019.2)            |
| Elevated β2-MG (ug/L), n (%)                        | 13 (92.9)                      |
| Urine N-acetyl-β-D-glucosidase (NAG) (U/L), median (IQR) | 21.1 (14.5,37.3)              |
| Elevated urine N-acetyl-β-D-glucosidase (NAG) (U/L), n (%) | 13 (92.9)                      |
| Retinol-Binding Protein (RBP) (mg/L), median (IQR)   | 1.2 (0.5,2.9)                  |
| Elevated retinol-Binding Protein (RBP) (mg/L), n (%) | 9 (64.3)                       |

*Fourteen (21.2%) of the 66 IgG4-RKD+ patients had been tested for renal tubular function.

The renal tubular function was also impaired. Urine specific gravity was reduced in 4.5% of the 66 patients. Among the 14 IgG4-RKD + patients who had specific renal tubular function tested, the three indexes of β2-MG, NAG and RBP were simultaneously elevated in 9 (64.3%) patients. The median β2-MG, NAG and RBP of all the IgG4-RKD patients were 2282.5 ug/L (IQR, 758, 8019.2), 21.1 U/L (IQR, 14.5, 37.3) and 1.2 mg/L (IQR, 0.5, 2.9), respectively, which were all higher than the normal range.

**Risk Factors associated with IgG4-RKD+**

As shown in Table 3, older age at onset (OR = 1.028, 95% CI, 1.005–1.051; P = 0.015), older age at diagnosis (OR = 1.035, 95% CI, 1.011–1.059; P = 0.004), >=3 organs involvement (OR = 3.473, 95% CI, 1.719–7.020; P = 0.001), retroperitoneal fibrosis (OR = 4.653, 95% CI, 2.566–8.438; P < 0.001), high level of ESR (OR = 1.014, 95% CI, 1.004–1.023; P = 0.003), low serum C3 levels (OR = 0.384, 95% CI, 0.164–0.902; P = 0.028) were associated with higher rate of IgG4-RKD+ in univariate analysis. Female (OR = 0.498, 95% CI, 0.282–0.881; P = 0.017), allergic disease (OR = 0.531, 95% CI, 0.300-0.939; P = 0.029), salivary gland involvement (OR = 0.579, 95% CI, 0.341–0.983; P = 0.043), and high level of Hb (OR = 0.970, 95% CI, 0.956–0.985; P < 0.001) were the protective factors of IgG4-RKD+. 
Table 3

However, only $\geq 3$ organs involvement (OR = 6.212, 95% CI, 1.095–35.240; $P=0.039$), retroperitoneal fibrosis (OR = 12.460, 95% CI, 3.080–50.407; $P<0.001$) and serum C3 levels (OR = 0.202, 95% CI, 0.045–0.902; $P=0.036$) remained significant after multivariate analysis (Fig. 2).

### Pathological findings

In total, 6 patients with IgG4-RKD underwent renal biopsy; all of the 6 (100%) patients had TIN. TIN in 1 case (16.6%) was associated with glomerular disease. Membranous nephropathy was the cause of glomerular disease in this case.

All the patients with TIN had a lymphoplasmocytic (LPC) infiltrate with fibrosis. The LPC infiltration was diffuse in 3 patients and patchy in the other 3 patients. In all of the 6 patients with TIN, IgG4 staining demonstrated $>10$ IgG4 + plasma cells per high-power field (in the most concentrated area), and all these patients fulfilled the Raissian criteria for IgG4-TIN [13].

### Radiological Findings

We used contrast-enhanced CT to identify radiological abnormalities in IgG4-RKD + patients except those with renal dysfunction. Sixty-three of the 66 IgG4-RKD + patients exhibited characteristic findings of the kidney radiology. Among them, 14 patients were presented with more than one kind of lesion. The most common finding is multiple, often bilateral, hypodense lesions in 32 (48.5%) IgG4-RKD + patients, which are called small cortical hypodense nodules (Fig. 3A), followed by ureteric obstruction and
hydronephrosis related to RPF in 22 (33.3%) patients (Fig. 3B), and thickening of the renal pelvic wall in 18 (27.3%) IgG4-RKD+ patients (Fig. 3C). Besides, diffuse patchy involvement, tumor-like less-enhanced mass and rim-like lesion were observed in 8 (12.1%), 2 (3.0%) and 1 (1.5%) patient, respectively.

**Discussion**

In this study, we compared the demographic, clinical, and laboratory characteristics of 66 IgG4-RKD+ patients and 384 IgG4-RKD- patients, as well as describing the radiological and pathological findings in patients with IgG4-RKD+. To our best knowledge, this is the largest case-control study of IgG4-RKD+ and IgG4-RKD- phenotypes.

IgG4-RD is manifested by typical clinical features, including tumor-like lesions, dense infiltration with IgG4-positive plasma cells, and extensive fibrosis of multiple organs. There is a great variability of disease manifestations for IgG4-RD, and the identification of different IgG4-RD subgroups is crucial, as a consequence of significant disparities in the characteristics of IgG4-RD regarding different organs [6, 14]. In our study, the frequency of kidney involvement in IgG4-RD patients was 14.7%, which is lower than that of Japan (23.7%) and Mexico (24.6%) [6, 15], but similar to that of UK study [11]. The heterogeneity of IgG4-RKD+ definition and ethnicity in various studies may explain for this diversity. The following organs were found more commonly involved in IgG4-RKD+ patients, including salivary gland, lymph nodes and pancreas. In addition, multi-organ involvement was common in IgG4-RKD+ patients. Therefore, it is necessary to perform a general checkup to obtain a comprehensive view of the patients especially for patients with IgG4-RKD+.

Involvement of three or more organs, retroperitoneal fibrosis and low serum C3 level were risk factors for the kidney disease in IgG4-RD patients. IgG4-RD is a multi-organ immune-mediated condition that could influence almost any organ system in the body. More involved organs may suggest the higher activity of disease. In most cases, IgG4-RKD+ is diagnosed in the context of known extrarenal IgG4-RD or active status of IgG4-RD. With progressive renal decline or detection of characteristic radiological features when evaluating extrarenal IgG4-RD, Kidney involvement became evident [13, 16], which may explain for the association between involvement of 3 or more organs and IgG4-RKD+. Additionally, renal involvement may appear as an intrinsic kidney disease (IgG4-RKD+) or as a consequence of ureteric obstruction from retroperitoneal fibrosis (IgG4-RPF). IgG4-RPF often concentrated in the periaortic region and ureters can be entrapped, leading to hydronephrosis and renal injury. Therefore, it is reasonable that retroperitoneal fibrosis is a risk factor for IgG4-RKD+.

There are also some interpretations for the association of low serum C3 levels and IgG4-RKD+. The first descriptions of IgG4-TIN was previously described as “idiopathic hypocomplementememic tubulointerstitial nephritis with extensive tubulointerstitial deposits [17]. Only about 16–34% of IgG4-RD patients have low serum complement levels, despite that hypocomplementemia is a feature of IgG4-RD. Nevertheless, more than 50% of patients with active IgG4-TIN have low concentration of complement [13, 16]. Therefore, hypocomplementemia is considered an important serological feature of the disease [18]. In our study,
hypocomplemenemia was found in 57.7% of IgG4-RKD+ patients, which is consistent with previous studies. Wang Rong et al found that complement activation may promote the development of IgG4-RKD+ [19]. Therefore, this study added insights into the hypocomplemenemia in IgG4-RKD+ patients. Low serum C3 level was found a risk factor for the development of IgG4-RKD+. Hypocomplementaemia is not characteristic feature of most IgG4-RD patients, which often suggests the existence of IgG4-RKD+, thus scrutiny is necessary.

In previously reported studies, kidney function in IgG4-RKD+ patients varies from normal to renal failure, and the development of renal dysfunction also varies from relatively acute to slowly progressive [13, 16, 18, 20, 21]. In our cohort, the renal function was impaired manifesting as the reduced eGFR, elevated blood urea nitrogen, elevated serum creatine and abnormal specific renal tubular function test. It could be attributed to IgG4-related TIN in the patients, or to the glomerular disease. IgG4-related TIN occurred in the vast majority of IgG4-RKD+ patients, and MGN was reported less than that. Consistent with the rates in previous studies, IgG4-related TIN occurred in all the 6 IgG4-RKD+ patients who had received renal biopsy. In the urinalysis in IgG4-related TIN, we could find typically mild to moderate proteinuria, as well as occasionally the presence of white blood cells [16], which was also consistent with our result. For IgG4-RD patients, it is necessary to carry out urine routine test and renal function test (both glomerular and tubular function), in order to timely detect glomerular and renal tubular lesions.

Main abnormalities on renal imaging were revealed in a total of 56 (84.8%) of IgG4-RKD+ patients: multiple low-density nodules, hydronephrosis and thickening of renal pelvic wall. Similar with previous studies, there were also some other imaging manifestations in our cohort, including diffuse patchy involvement of the bilateral kidneys and rim-like lesion of the kidney [11, 22]. CT was the most common mode of renal imaging, including PET-CT, which is increasingly used. PET-CT could contribute to excluding malignancy with little radiative damage. Moreover, PET-CT is helpful for discovering the involvement of some silent lesions, however, its cost should also be taken into account.

One of the limitations of this study is its retrospective nature, indicating that some affected organs may be neglected, although most patients have undergone general examinations, including FDG-PET. Moreover, only a small number of IgG4-RKD+ cases were diagnosed based on renal biopsy. Compared to biopsy from superficial tissue, there would be higher risk of iatrogenic trauma when patients receive deep kidney biopsy, thus some patients would not accept it.

Conclusion

In summary, we have specified demographic, clinical, and laboratory differences between IgG4-RKD+ patients and IgG4-RKD. IgG4-RKD+ patients had older age at onset and older age at diagnosis. The male to female ratio of IgG4-RKD+ patients is significantly higher. The most commonly involved organs of IgG4-RKD+ patients were salivary gland, lymph nodes and pancreas. Involvement of three or more organs, retroperitoneal fibrosis and low serum C3 level were risk factors for the kidney disease in IgG4-RD
patients. These findings indicate potential differences in pathogenesis of these two phenotypes with or without kidney involvement.

List Of Abbreviations

IgG4-RD, IgG4-related disease
IgG4-RKD, IgG4-related disease
RPF, retroperitoneal fibrosis
AIP, autoimmune pancreatitis
TIN, tubulointerstitial nephritis
MGN, membranous glomerulonephropathy
EAACI, European Academy of Allergy and Clinical Immunology
CRP, C-reactive protein
ESR, erythrocyte sedimentation rate
OR, odd’s ratio
CI, confidence interval
IQR, interquartile range
Hb, hemoglobin
eGFR, estimated glomerular filtration rate
β2-MG, β2-microglobulin
NAG, urine N-acetyl-β-D-glucosidase
RBP, retinol-binding proteinphosphate
TBM, tubular basement membrane
LPC, lymphoplasmocytic.

Declarations
Ethics approval and consent to participate According to national regulations and in accordance with the Declaration of Helsinki, data protection authority and medical research ethical committee gave their approval. Written informed consent was obtained from all participants.

Consent for publication Not applicable.

Availability of data and materials The datasets generated and/or analyzed during the current study are not publicly available for ethical reasons, as well as privacy reasons but are available from the corresponding author on reasonable request.

Competing interests The authors declare that they have no competing interests.

Funding This work was supported by Project (RDH2020-03) supported by Peking University People's Hospital Scientific Research Development Funds.

Authors' contributions All authors were involved in drafting the article and revising it critically, and all authors have read and approved the submitted version. ZQZ, GJY, LYY and LZG contributed to the design and conception of the study. LAC, ZXY, CXY, SQY and WZQ were responsible for acquisition of data. WZF and WY performed the statistical analyses and contributed to the interpretation of data. ZQZ was the major contributor in writing the manuscript.

Acknowledgements Thanks to the participants, both patients, and staff for making this study possible.
