Abstract
We evaluate the form factors describing the exclusive decay $B \to \pi \ell \nu$ by using a Constituent Quark-Meson model based on an effective quark-meson Lagrangian (CQM). The model allows for an expansion in the pion momenta and we consider terms up to the first order in the pion field derivatives. We compute the leading terms in the soft pion limit and consider corrections to this limit.

We evaluate the form factors describing the exclusive decay $B \to \pi l \nu$ by using a Constituent Quark-Meson model based on an effective quark-meson Lagrangian (CQM). The model allows for an expansion in the pion momenta and we consider terms up to the first order in the pion field derivatives. We compute the leading terms in the soft pion limit and consider corrections to this limit.

I. INTRODUCTION

The investigation of the semileptonic decay $B \to \pi l \nu$ is relevant for the extraction of the Kobayashi-Maskawa matrix element $V_{ub}$. The analysis of this exclusive decay mode would offer a method alternative to the inclusive semileptonic $B$ decay for the study of the $b \to u$ transition. A precise measurement of this process is one of the main aims of the future $B$-factories.

On the theoretical side this decay process has received large attention in literature (see for example the review in [B]) since it offers an example of heavy-to-light quark transition computable by the presently available theoretical methods.

The present note is devoted to the study of the $B \to \pi l \nu$ decay mode in the framework of the Constituent-Quark-Meson (CQM) model [B]. In this model the transition amplitudes are evaluated by computing diagrams in which heavy and light mesons are attached to quark loops. Moreover, the light chiral symmetry restrictions and the heavy quark spin-flavour symmetry dictated by the Heavy-Quark-Effective-Theory (HQET) are both implemented. The advantage of such a description is the reduced number of free parameters with respect to an effective Lagrangian at the meson level with no dynamical assumptions [B].

A short glossary, useful to go through the results reported here, is in order. We call $H$ the field representing the low-lying heavy meson doublet $(0^{-}, 1^{-})$ [B] and $Z_H$ the heavy field renormalization constant, induced by loop effects and $\Delta_H$ the difference between the $H$ meson doublet mass and the mass of the constituent heavy quark. $\Delta_H$ is an adjustable parameter of the model and we restrict to $\Delta_H = 0.4 \pm 0.1$ GeV since only this range of values allows for a good phenomenology of semileptonic weak decays (for a discussion see [B]). For the definition of the model, it is important to fix the regularization procedure allowing to calculate explicitly the quark loop integrals. We use the Schwinger proper time regularization method, assuming, as ultraviolet (UV) and infrared (IR) cut-off, $\Lambda \simeq 1.25$ GeV and $\mu \simeq 0.3$ GeV respectively. Another parameter is the constituent light quark mass $m$ that we have fixed in [B] to the value: $m = 0.3$ GeV for $u$ and $d$ flavours.

II. $B \to \pi$ FORM FACTORS

We consider the weak current matrix element for the semileptonic $B \to \pi$ transition which is given by $(q = p - q_\pi)$:

$$\langle \pi(q_\pi)|V^\mu(q)|B(p)\rangle = \left[(p + q_\pi)^\mu + \frac{m_2^2 - m_B^2}{q^2}q^\mu\right] F_1(q^2)$$

$$- \left[\frac{m_2^2 - m_B^2}{q^2}q^\mu\right] F_0(q^2).$$

with $F_1(0) = F_0(0)$. The calculation of the semileptonic process proceeds through the evaluation of the diagrams in Fig. 1, 2 and 3. Fig. 1 gives rise to a non derivative coupling. Fig. 2a and Fig. 2b are polar diagrams where the pion is introduced through a derivative interaction term: in Fig. 2a the intermediate particle is the vector meson particle belonging to the $H$ heavy meson multiplet; in Fig. 2b the intermediate particle is the scalar $(J^P = 0^+)$ meson particle belonging to the positive parity $S$ heavy meson multiplet (this multiplet is built similarly to $H$ and contains also an axial vector meson $J^P = 1^{+}$ state). The diagram in Fig. 2b represents only a correction to the chiral symmetry limit. To obtain the contribution of Fig. 1, an expansion of the chiral rotated light quark field, $\chi$, up to the first order in $\pi$ is needed [B]. In the case of Fig. 2 and Fig. 3 the same expansion is truncated at the zero-th order. The $\chi$ field, as defined in [B], is given by $\chi = \xi q$ being $q$ the usual spinor field describing the light degrees of freedom and $\xi = e^{i\pi f_\pi q_\pi}$, with $f_\pi = 130$ MeV.
The diagram in Fig. 1 produces a result proportional to the leptonic $B$-decay constant; its predictions are expected to be valid at small pion momenta, near the zero recoil point: $q_0^2 \approx (m_B - m_\pi)^2$. One obtains, from this non-derivative (ND) coupling, the contributions:

$$F_0^{\text{ND}} = \frac{f_B}{f_\pi} \quad (2)$$
$$F_1^{\text{ND}} = \frac{f_B}{2f_\pi}, \quad (3)$$

where $f_B$ is the $B$ leptonic decay constant. The CQM-model evaluation of $f_B$ is given in [3]. Neglecting a smooth logarithmic dependence, the heavy meson mass dependence of $f_B$, as predicted by the HQET, is as follows:

$$f_B = \frac{\hat{F}}{\sqrt{m_B}} \quad (4)$$

where $\hat{F}$ parametrises the leading term in the decay constant $f_B$ (see for example [1]). Next we consider the polar diagrams in Fig. 2. First of all let us consider the diagram in Fig. 2(a) which gives a contribution proportional to $g\hat{F}$, where $g$ is the $HH\pi$-strong coupling constant. One obtains the following contribution to $F_1$ [3, 4]:

$$F_1^{\text{Pol}}(q^2) = \frac{\hat{F}g}{f_\pi \sqrt{m_B}} \frac{1}{1 - q^2/m_B^2}. \quad (5)$$

where $g$ is the $HH\pi$-strong coupling constant evaluated in [3] (see also [3] for an evaluation in the framework of the QCD sum-rule approach and [3] in the framework of the effective meson Lagrangian approach). The diagram in Fig. 2(b) contributes to the other form factor:

$$F_0^{\text{Pol}}(q^2) = \frac{1}{m_B - m_\pi} \left( \frac{hm_\pi \sqrt{m_B \hat{F}}}{f_\pi} \right) \frac{1}{1 - q^2/m_B^2}. \quad (6)$$

where $h$ is the $HS\pi$-strong coupling constant evaluated in [3], $B^{**}$ is the $0^+$ state in the $S$ multiplet $(0^+, 1^+)$ and $\hat{F}^+$ is the $B^{**}$ leptonic decay constant analogous to $\hat{F}$. All the coupling constants appearing in these equations can be computed in the CQM. The polar results [3] and [4] should be reliable near the poles, i.e. again for $q^2$ large, around $q_0^2$, the zero recoil point. We shall discuss below a procedure to extrapolate these results to lower $q^2$ values. For future reference we quote here the values of the expressions [3] and [3] at $q^2 = 0$:

$$F_1^{\text{Pol}}(0) = 0.52 \pm 0.01 \quad (7)$$
$$F_0^{\text{Pol}}(0) = 0.012 \pm 0.001. \quad (8)$$

They are obtained with the values $\hat{F} = 0.34 \pm 0.02$, $\hat{F}^+ = 0.24 \pm 0.03$, $g = 0.46 \pm 0.04$, $h = -0.76 \pm 0.13$ [3].

The results obtained so far are not new; they have been obtained by several groups and our contribution consists here only in the calculation, within the CQM-model, of the various parameters appearing in the previous equations. The model however allows to consider a new contribution, depicted in Fig. 3: it differs from the ND (non-derivative) term since it is derivative and from the polar term because it does not contain couplings to resonances. The current directly couples to the quark in this case rather than to the heavy meson as in the polar contribution. Both the polar and the new "direct" contributions can be reliably calculated only at large $q^2$, note however that differently from (7) and (8) for the polar terms, the relation $F_1(0) = F_0(0)$ will be automatically satisfied by the new contributions to be described in the following. We compute them by a straightforward application of the basic rules of the CQM. As the current will transform a heavy meson into a light one in this case, we need the interaction of the pion with light quarks. We recall here the corresponding Lagrangian. The term relevant for the calculation will be the one containing an odd number of pions. The following term defines the Feynman rule we follow to insert the pion in our CQM diagram:

$$\mathcal{L} = \bar{\chi}(iD^\mu \gamma_\mu + \mathcal{A}^\mu \gamma_\mu \gamma_5)\chi - m_\chi \bar{\chi} \chi + \frac{f_\pi^2}{8} \partial_\mu \Sigma^\dagger \partial^\mu \Sigma. \quad (9)$$

Apart from the mass term, $\mathcal{L}$, is chiral invariant. Here $\chi$ is the chiral rotated light quark field quoted above, $\Sigma = \xi^2$ and $\pi$ is the $3 \times 3$ matrix representing the flavour $SU(3)$ octet of pseudoscalar mesons. Moreover, $D_\mu = \partial_\mu - i\mathcal{V}_\mu$ and:

$$\mathcal{V}^\mu = \frac{1}{2}(\xi^\dagger \partial^\mu \xi + \xi \partial^\mu \xi^\dagger), \quad (10)$$
$$\mathcal{A}^\mu = \frac{1}{2}(\xi^\dagger \partial^\mu \xi - \xi \partial^\mu \xi^\dagger). \quad (11)$$

where [10] generates couplings of an even number of mesons to the $\bar{\chi}\chi$ pair, while [11] gives an odd number of $\pi$ fields.

An explicit calculation of the mentioned diagram gives:

$$F_1^{\text{Dir}}(q^2) = \frac{2}{f_\pi} \sqrt{\frac{Z_H}{m_H}} \left[ q_\pi(C - m_A) + m_H B \right] \quad (12)$$
$$F_0^{\text{Dir}}(q^2) = \frac{2}{f_\pi} \sqrt{\frac{Z_H}{m_H}} \left[ \left( 1 - \frac{m_\pi^2 - m_B^2}{m_H^2} \right) q_\pi(C - m_A) \right. \right.$$

$$\left. \left. + m_H B \left( 1 + \frac{q^2}{m_H^2 - m_B^2} \right) \right] \right). \quad (13)$$

where:

$$A = \frac{1}{2q_\pi} (I_3(\Delta_H - q_\pi) - I_3(\Delta_H)) \quad (14)$$
$$B = m_A - m^2 Z(\Delta_H) \quad (15)$$
$$C = \frac{1}{2q_\pi} ((\Delta_H I_3(\Delta_H) - (\Delta_H - q_\pi)I_3(\Delta_H - q_\pi)) \right). \quad (16)$$

2
and

\[ Z(\Delta) = \frac{N_c}{16\pi^{3/2}} \int_0^{1/\chi^2} \frac{ds}{s^{1/2}} e^{-sm^2} \times \int_0^1 dx e^{x\Delta^2(x)} [1 + \text{erf}(\Delta(x)\sqrt{\pi})] \]

\[ I_3(\Delta) = \frac{N_c}{16\pi^{3/2}} \int_0^{1/\chi^2} \frac{ds}{s^{1/2}} e^{-s(m^2-\Delta^2)} \times (1 + \text{erf}(\Delta(\sqrt{\pi})) \]  

(17)

(18)

where \( q^2_0 = (q_x, 0, 0, q_x) \) is the pion 4-momentum \((m_\pi \to 0)\) and \( \Delta(x) = \Delta - xq_\pi \). We observe that the soft pion limit of the previous expression brings \( Z(\Delta) \to I_4(\Delta) \) defined in [3]. Notice that in Eqs. (12, 13) the \( \Delta \) dependence arises because of \( q_\pi = (m_B^2 - q^2)/2m_B \) and can be computed numerically. We find:

\[ F_1^{\text{Dir}}(q^2 = 0) = F_0^{\text{Dir}}(q^2 = 0) = 0.13 \pm 0.05 \]  

(19)

The error in the numerical evaluations is due to the variation of \( \Delta_H \) in the range of values \( 0.3 - 0.5 \). The contribution of the direct diagram in Fig. 3 is an appreciable 10% to 30% correction, depending on the region in \( q^2 \).

Since the three contributions to the form factors \( F_0 \) and \( F_1 \) are independent, we can sum them up, with the result:

\[ \hat{F}_j(q^2) = \frac{f_B}{(j + 1)f_0} + F_0^{\text{Dir}}(q^2) + \frac{F_{j0}(0)}{1 - q^2/m_j^2} \]  

(20)

where \( m_1 = m_{B^*}, m_0 = m_{B^*} \) and we have marked the form factors with a hat to stress that this formula does not hold in the whole \( q^2 \) interval. As a matter of fact, as discussed above, the \( q^2 \) range in which [20] is expected to approximate reliably the form factors is around the zero recoil point: \( q^2 \approx q_0^2 \approx m_B^2 \). This follows from the fact that the model allows for a systematic derivative expansion, whose first terms are represented by \( \hat{F}_j \); terms of higher order in the pion derivatives, which can be important at small \( q^2 \), are suppressed for large \( q^2 \). This observation gives us a hint to extrapolate to smaller values of \( q^2 \). Writing:

\[ F_j(q^2) = \hat{F}_j(q^2)G_j(q^2) \]  

(21)

where \( j \in \{0, 1\} \); this parameterisation has to satisfy

\[ G_j(q^2_0) = 1 \]  

(22)

as \( q^2 \approx q_0^2 \) is the region where \( \hat{F}_j \) are a good approximation of the form factors. Another condition that has to be satisfied is the constraint:

\[ \hat{F}_1(0)G_1(0) = \hat{F}_0(0)G_0(0), \]  

(23)

which follows from \( F_1(0) = F_0(0) \). It is reasonable to assume that the corrections to \( G_j(q^2) \equiv 1 \) arise from terms with extra pion derivatives. Therefore we put

\[ G_j(q^2) = 1 - \frac{E_\pi}{\alpha_j\Lambda_\chi} = 1 - \frac{(q_x \cdot p)}{\alpha_jm_B\Lambda_\chi}, \]  

(24)

where \( E_\pi \) is the pion energy in the \( B \) rest frame, \( \Lambda_\chi = 1 \) GeV and \( \alpha_j \) are free parameters. Since (24) is equivalent to (under the assumption that \( q_2^0 \ll m_B^0 \)):

\[ G_j(q^2) = 1 + \frac{q^2 - m_B^2}{2m_B\Lambda_\chi \alpha_j} \]  

(25)

condition [24] is automatically satisfied. Formula [23] implies that \( \alpha_0 \) and \( \alpha_1 \) are related:

\[ \frac{m_B}{2\Lambda_\chi \alpha_1} = 1 - \left(1 - \frac{m_B}{2\Lambda_\chi \alpha_0}\right) \frac{\hat{F}_0(0)}{\hat{F}_1(0)} \]  

(26)

We could fix one of the two parameters from experimental data, were they available. For the time being, in absence of such information, we have to use some theoretical input. There exist many theoretical calculations of the \( B \to \pi \) couplings; for example quark models [10, 12] predict \( \hat{F}_0(0) = 0.20 \) to 0.50 with the exception of [13] which gives a very small value \( \hat{F}_0(0) = 0.09 \). Chiral perturbation theory together with heavy quark effective theory gives \( \hat{F}_0(0) = 0.38 [14] \). QCD sum-rules give \( \hat{F}_0(0) = 0.25 \) to 0.40 [14, 16]. Finally lattice results are \( \hat{F}_0(0) = 0.27 \) to 0.35 [17, 19]. We take as an input the result of the QCD sum rules calculation of [14] that gives \( \hat{F}_0(0) = 0.30 \pm 0.04 \), in this way we obtain \( \alpha_0 = 3.6 \). It is interesting to note that the rather large value of \( \alpha_0 \) obtained by this procedure indicates that the effective parameter of the derivative expansion is not of the order of 1 GeV \( (\simeq \Lambda_\chi) \), but larger, which means that, in spite of the fact that this approximation should hold only at zero recoil point, it gives reasonable estimates also at lower \( q^2 \). This conclusion is corroborated by our estimate of the first correction to the leading terms of the form factors, i.e. \( F_1^{\text{Dir}}(q^2) \), which is appreciable, but not very large (10% to 30% of the total).

Letting the parameter \( \alpha_0 \) vary by 20% allows to see how the parameterisation affects the result. In the Table the two form factors \( F_1 \) and \( F_0 \), including the CQM correction, are given for few \( q^2 \) values near the maximum value \( q_{\max}^2 \) of 26.4 GeV. The error refer a variation of the values of \( \alpha_0 \) in the range (2.9–4.3).

We have also reported results from other theoretical approaches. Let us note, as a concluding remark, that our calculation includes, differently from other approaches based on the derivative expansion, some deviations from the leading behaviour expected in the soft pion limit. These extra terms, while sizeable, are not such to change qualitatively the simple pole behaviour predicted by the chiral effective theory.

| $F_0^{B\pi}$ | 0.46$^{+0.10}_{-0.10}$ | 0.49$^{+0.10}_{-0.10}$ | 0.56$^{+0.12}_{-0.10}$ | –          |

TABLE I. Form factors $F_1$ and $F_0$ at high $q^2$ values, near ($q^2_{max} \approx 26.4$ GeV$^2$) for $B \to \pi$ semi-leptonic decays in CQM model and comparison with other calculations. The error quoted for our result comes only from a 20% variation in the parameter controlling the evolution from large $q^2$ values (where the calculation is more reliable) to smaller ones.
