WEAK TYPE (1,1) BOUND CRITERION FOR SINGULAR INTEGRAL WITH ROUGH KERNEL AND ITS APPLICATIONS

YONG DING AND XUDONG LAI

Abstract. In this paper, a weak type (1,1) bound criterion is established for singular integral operator with rough kernel. As some applications of this criterion, we show some important operators with rough kernel in harmonic analysis, such as Calderón commutator, higher order Calderón commutator, general Calderón commutator, Calderón commutator of Bajsanski-Coifman type and general singular integral of Muckenhoupt type, are all of weak type (1,1).

1. INTRODUCTION

Singular integral theory is a fundamental and important topic in harmonic analysis. It is intimately connected with the study of complex analysis and partial differential equations. Real variable methods of singular integral for higher dimension were original by A. P. Calderón and A. Zygmund [6] in the 1950’s. Later, large numbers of works are developed in this area. Despite the intensive research over the last six decades, there are still many problems in the theory of singular integral which remain open and deserve to be explored further. For example, there is no general $L^1$ theory of rough singular integral, singular integral along curves and Radon transforms (see [32]).

It is well known that the $L^1$ boundedness is not true for many integral operators in harmonic analysis, such as Hilbert transform, Riesz transforms, Hardy-Littlewood maximal operator, and so on. As a substitution, we consider the weak type (1,1) bound and use interpolation and dual argument, we can get all $L^p$ bound for $1 < p < +\infty$. So it is an important problem to establish weak type (1,1) boundedness in the $L^1$ theory of singular integral operator and maximal operator. Usually, the weak type (1,1) bound can be established by using the classical Calderón-Zygmund decomposition if its kernel has enough smoothness. However, if the kernel is rough, then the standard Calderón-Zygmund theory cannot be applied directly. In fact it is a quite difficult problem to prove the weak type (1,1) boundedness of the integral operator with rough kernel. We refer to see the nice works by M. Christ [10], M. Christ and J. Rubio de
Francia [12], M. Christ and C. Sogge [13], S. Hofmann [22], A. Seeger [29] [30], P. Sjögren and F. Soria [31] and Tao [33] about this topic.

However, the papers mentioned above are considered for some special operators. In this paper, we are going to study the general \( L^1 \) theory of rough singular integral operator. More precisely, we try to give a criterion that could deal with weak type \((1,1)\) boundedness of a class of singular integrals with non-smooth kernel.

Before state our main result, let us firstly give our motivations from some basic examples. The first example is singular integral with convolution homogeneous kernel. Suppose \( \Omega \) is a function defined on \( \mathbb{R}^d \setminus \{0\} \) satisfying

\[
\Omega(rx') = \Omega(x'), \text{ for any } r > 0 \text{ and } x' \in S^{d-1},
\]

(1.1)

\[
\int_{S^{d-1}} \Omega(\theta) d\theta = 0
\]

and

(1.2)

\[
\Omega \in L^1(S^{d-1}),
\]

where and in the sequel, \( d\theta \) denotes the surface measure of \( S^{d-1} \). Then it is easy to see that the following singular integral is well defined for \( f \in C_c^\infty(\mathbb{R}^d) \),

(1.4)

\[
Tf(x) = \text{p.v.} \int_{\mathbb{R}^d} \frac{\Omega(x-y)}{|x-y|^d} f(y) dy.
\]

In 1956, Calderón and Zygmund [7] gave the \( L^p \) boundedness of \( T \).

**Theorem A** ([7]). Suppose that \( \Omega \) satisfies the conditions (1.1) and (1.3), then the singular integral \( T \) defined in (1.4) extends to a bounded operator on \( L^p(\mathbb{R}^d) \) (\( d \geq 2 \)) for \( 1 < p < \infty \) if \( \Omega \) satisfies one of the following conditions:

(i) \( \Omega \) is odd;

(ii) \( \Omega \) is even and \( \Omega \in L \log^+ L(S^{d-1}) \) satisfies (1.2).

For the case \( p = 1 \), it is a very difficult problem to show that \( T \) is of weak type \((1,1)\). In 1988, M. Christ and Rubio de Francia [12] and in 1989, S. Hofmann [22] independently gave weak type \((1,1)\) boundedness of \( T \) for \( d = 2 \). Later, in 1996, A. Seeger [29] established the weak type \((1,1)\) boundedness of \( T \) for all dimension \( d \geq 2 \). Now let us sum up their nice results as follows.

**Theorem B.** Suppose that \( \Omega \) satisfies the conditions (1.1), (1.2) and (1.3).

(i) (see [12]). If \( \Omega \in L \log^+ L(S^1) \), \( T \) is of weak type \((1,1)\) for \( d = 2 \). In an unpublished paper, M. Christ and Rubio de Francia pointed out that they succeeded proving similar results hold also for \( d \leq 5 \);

(ii) (see [22]). If \( \Omega \in L^q(S^1)(1 < q \leq \infty) \), \( T \) is of weak type \((1,1)\) for \( d = 2 \);

(iii) (see [29]). If \( \Omega \in L \log^+ L(S^{d-1}) \), \( T \) is of weak type \((1,1)\) for \( d \geq 2 \).
The second example is Calderón commutator introduced by A. P. Calderón in his famous paper [2], which is defined by

\begin{equation}
T_{Ω,A}f(x) = \text{p.v.} \int_{\mathbb{R}^d} \frac{Ω(x-y)\cdot A(x) - A(y)}{|x-y|} \cdot f(y)dy,
\end{equation}

where \(A ∈ \text{Lip}(\mathbb{R}^d)\), the class of Lipschitz functions.

**Theorem C** (2 or see 3). Let \(d ≥ 2\). Suppose that \(Ω\) satisfies the conditions (1.1) and (1.3), then the commutator \(T_{Ω,A}\) maps \(L^p(\mathbb{R}^d)\) to itself for \(1 < p < ∞\) if \(Ω\) satisfies one of the following conditions:

(i) \(Ω\) is even;

(ii) \(Ω ∈ L\log^+ L(\mathbb{S}^{d-1})\) is odd and satisfies

\begin{equation}
\int_{\mathbb{S}^{d-1}} Ω(θ)θ^αdθ = 0, \text{ for all } α ∈ \mathbb{Z}^d_+ \text{ with } |α| = 1.
\end{equation}

Here and in the sequel, \(α = (α_1, \cdots , α_d) ∈ \mathbb{Z}^d_+\) is a multi-indices, \(|α| = \sum_{j=1}^d α_j\) and \(x^α = \prod_{i=1}^d x_i^{α_i}\) when \(x ∈ \mathbb{R}^d\).

For a long time, an open problem is that whether Calderón commutator \(T_{Ω,A}\) is of weak type \((1,1)\) if \(Ω\) satisfies (1.1), (1.6) and \(Ω ∈ L\log^+ L(\mathbb{S}^{d-1})\). In Section 5 we will give a confirm answer to this problem as an application of our main result.

By careful observation of singular integral with homogeneous kernel in (1.4) and Calderón commutator in (1.5), we conclude that singular integrals in (1.4) and (1.5) can be formally rewritten in the following way,

\begin{equation}
T_{Ω}(f)(x) = \text{p.v.} \int_{\mathbb{R}^d} Ω(x-y)K(x,y)f(y)dy
\end{equation}

where \(Ω\) satisfies (1.1), (1.3) and \(K\) satisfies

\begin{equation}
|K(x,y)| ≤ \frac{C}{|x-y|^d},
\end{equation}

and the regularity conditions: for a fixed \(δ ∈ (0,1]\),

\begin{equation}
|K(x_1,y) - K(x_2,y)| ≤ C\frac{|x_1 - x_2|^δ}{|x_1 - y|^{d+δ}}, \quad |x_1 - y| > 2|x_1 - x_2|,
\end{equation}

\begin{equation}
|K(x,y_1) - K(x,y_2)| ≤ C\frac{|y_1 - y_2|^δ}{|x - y_1|^{d+δ}}, \quad |x - y_1| > 2|y_1 - y_2|.
\end{equation}

In this paper, we are interested in when \(T_Ω\) is of weak type \((1,1)\). Our main result is the following.

**Theorem 1.1.** Suppose \(K\) satisfies (1.8) and (1.9). Let \(Ω\) satisfy (1.1) and \(Ω ∈ L\log^+ L(\mathbb{S}^{d-1})\). In addition, suppose \(Ω\) and \(K\) satisfy some appropriate cancellation conditions such that \(T_Ωf(x)\) in (1.7) is well defined for \(f ∈ C_0^∞(\mathbb{R}^d)\) and extends to a bounded operator on \(L^2(\mathbb{R}^d)\) with bound \(C\|Ω\|_{L\log^+ L}\). Then for any \(λ > 0\), we have

\[\lambda m(\{x ∈ \mathbb{R}^d : |T_Ωf(x)| > λ\}) \lesssim C_Ω\|f\|_1,\]
where $C_\Omega$ is a finite constant which depends on $\Omega$ (see the definition in (2.1)).

It should be pointed out that it is difficult to assume uniform cancellation conditions of $\Omega$ in our main result, since it is dependent of $K(x,y)$, such as the conditions (1.2) and (1.6). Essentially, in the theory of singular integral, the cancellation conditions of $\Omega$ play a key role in proving the $L^2$ boundedness of a singular integral with homogeneous kernel. However, in the present paper, the cancellation conditions actually do not need to be used in our proof of weak type (1,1) boundedness of the singular integral once it is of strong type (2,2).

Note that the conditions in Theorem 1.1 are easily verified; therefore Theorem 1.1 gives a weak type (1,1) bound criterion, which has its own interest in the theory of singular integral. In fact, one will see that applying Theorem 1.1 some important and interesting integral operators in harmonic analysis, such as the famous Calderón commutator, higher order Calderón commutator, general Calderón commutator, Calderón commutator of Bajsanski-Coifman type and general singular integral of Muckenhoupt type are all of weak type (1,1), see Section 5 for more details.

Since the kernel $\Omega(x-y)K(x,y)$ of $T_\Omega$ is non-smooth for $\Omega \in L\log^+ L(S^{d-1})$, the standard Calderón-Zygmund theory can not be applied to proving the weak (1,1) boundedness of $T_\Omega$. When the dimension $d = 2$, M. Christ and Rubio de Francia [12] or S. Hofmann [22], used the $TT^*$ method to get the weak type (1,1) bound for rough singular integral operator defined in (1.4). The $TT^*$ method was original by C. Fefferman [17] (see [20], [14], [29], [30] and [15] for more applications in singular integrals). However, for the higher dimensions this method may not be useful. In this paper, our strategy to prove Theorem 1.1 is based on partly the nice ideas in [29]. More precisely, we use the microlocal decomposition of the kernel and some $TT^*$ argument in $L^2$ estimate in one part (see the proof of Lemma 2.3 in Section 3.3), which is similar to [29]. For the other part, we inset a multiplier operator of weak type (1,1) with a controllable bound so that the problem can be reduced to $L^1$ estimates of some oscillatory integrals (see the proof of Lemma 2.4 in Section 4). Since $T_\Omega$ is a non-convolution operator, the proof in this part is more complicated and we can not apply the properties of multiplier to oscillatory integrals. Thus we have to estimate the kernel of oscillatory integrals directly by using the method of stationary phase.

This paper is organized as follows. In Section 2 we complete the proof of Theorem 1.1 based on some lemmas, their proofs will be given in Section 3 and Section 4. In Section 5 we give some important applications of Theorem 1.1. Some open problems are listed in Section 6. Throughout this paper, the letter $C$ stands for a positive constant which is independent of the essential variables and not necessarily the same one in each occurrence. Sometimes we use $C_N$ to emphasize the constant depends on $N$. $A \lesssim B$ means $A \leq CB$ for some constant $C$. $A \approx B$ means that $A \lesssim B$ and $B \lesssim A$. For a set $E \subset \mathbb{R}^d$, we denote by $|E|$ or $m(E)$ the Lebesgue measure of $E$. We denote by $\mathcal{F}f$ or $\hat{f}$ the Fourier transform of $f$ which is defined by

$$\mathcal{F}f(\xi) = \int_{\mathbb{R}^d} e^{-i(x,\xi)} f(x) dx.$$
Z_+ denote the set of all nonnegative integers and Z_+^d = Z_+ \times \cdots \times Z_+. Moreover, \( \| \Omega \|_q := (\int_{S^{d-1}} |\Omega(\theta)|^q d\theta)^\frac{1}{q} \) and \( \| \Omega \|_{L^{\log^+ L}} := \int_{S^{d-1}} |\Omega(\theta)| \log(2 + |\Omega(\theta)|) d\theta \).

2. Proof of Theorem 1.1

In this section we give the proof of Theorem 1.1 based on some lemmas, their proofs will be given in Section 3 and Section 4.

We only focus on dimension \( d \geq 2 \). Let \( \Omega \in L \log^+ L(S^{d-1}) \) with \( \| \Omega \|_{L^{\log^+ L}} < +\infty \). Set the constant

\[ C_\Omega = \| \Omega \|_{L^{\log^+ L}} + \int_{S^{d-1}} |\Omega(\theta)|(1 + \log^+((\Omega(\theta))/\|\Omega\|_1)) d\theta, \]

where \( \log^+ a = 0 \) if \( 0 < a < 1 \) and \( \log^+ a = \log a \) if \( a \geq 1 \). Since \( \| \Omega \|_{L^{\log^+ L}} < +\infty \), one can easily check that \( C_\Omega \) is a finite constant. For \( f \in L^1(\mathbb{R}^d) \) and \( \lambda > 0 \), using the Calderón-Zygmund decomposition at level \( \frac{\lambda}{C_\Omega} \), we have the following conclusions (cf. see [32] for example):

1. \( f = g + b \);
2. \( \| g \|_2^2 \lesssim \lambda \| f \|_1 / C_\Omega \);
3. \( b = \sum_{Q \in \mathcal{Q}} b_Q \), suppb \( \subseteq Q \), where \( \mathcal{Q} \) is a countable set of disjoint dyadic cubes;
4. Let \( E = \bigcup_{Q \in \mathcal{Q}} Q \), then \( m(E) \lesssim \lambda^{-1} C_\Omega \| f \|_1 \);
5. \( \int b_Q = 0 \) for each \( Q \in \mathcal{Q} \) and \( \| b_Q \|_1 \lesssim \frac{\lambda}{C_\Omega} |Q| \), so \( \| b \|_1 \lesssim \| f \|_1 \) by (cz-iii) and (cz-iv).

By the property (cz-i), we have

\[ m(\{ x : |T_\Omega f(x)| > \lambda \}) \leq m(\{ x : |T_\Omega g(x)| > \lambda/2 \}) + m(\{ x : |T_\Omega b(x)| > \lambda/2 \}). \]

Hence, by Chebyshev’s inequality, the fact \( T_\Omega \) is bounded on \( L^2(\mathbb{R}^d) \) with bound \( C \| \Omega \|_{L^{\log^+ L}} \) and property (cz-ii), we get

\[ m(\{ x \in \mathbb{R}^d : |T_\Omega g(x)| > \lambda/2 \}) \leq 4 \| T_\Omega g \|_2^2 / \lambda^2 \lesssim \lambda^{-2} (\| \Omega \|_{L^{\log^+ L}} \| g \|_2)^2 \lesssim \lambda^{-1} C_\Omega \| f \|_1. \]

For \( Q \in \mathcal{Q} \), denote by \( l(Q) \) the side length of cube \( Q \). For \( t > 0 \), let \( tQ \) be the cube with the same center of \( Q \) and \( l(tQ) = tl(Q) \). Set \( E^* = \bigcup_{Q \in \mathcal{Q}} 2^{200} Q \). Then

\[ m(\{ x \in \mathbb{R}^d : |T_\Omega b(x)| > \lambda/2 \}) \leq m(E^*) + m(\{ x \in (E^*)^c : |T_\Omega b(x)| > \lambda/2 \}). \]

By the property (cz-iv), the set \( E^* \) satisfies

\[ m(E^*) \lesssim m(E) \lesssim \lambda^{-1} C_\Omega \| f \|_1. \]

Thus, to complete the proof of Theorem 1.1 it remains to show

\[ m(\{ x \in (E^*)^c : |T_\Omega b(x)| > \lambda/2 \}) \lesssim \lambda^{-1} C_\Omega \| f \|_1. \]

Denote \( \mathcal{Q}_k = \{ Q \in \mathcal{Q} : l(Q) = 2^k \} \) and let \( B_k = \sum_{Q \in \mathcal{Q}_k} b_Q \). Then \( b \) can be rewritten as \( b = \sum_{j \in \mathbb{Z}} B_j \). Taking a smooth radial nonnegative function \( \phi \) on \( \mathbb{R}^d \) such that \( \text{supp } \phi \subset \{ x : \frac{1}{2} \leq \)}
Lemma 2.1. With the notations above, we have

\[ |x| \leq 2 \] and \( \sum_j \phi_j(x) = 1 \) for all \( x \in \mathbb{R}^d \backslash \{0\} \), where \( \phi_j(x) = \phi(2^{-j}x) \). Define the operator \( T_j \) as

\[ T_j h(x) = \int_{\mathbb{R}^d} \Omega(x - y)\phi_j(x - y)K(x, y)h(y)dy. \] (2.3)

Then \( T_\Omega = \sum_j T_j \). For simplicity, we set \( K_j(x, y) = \phi_j(x - y)K(x, y) \). We write

\[ T_\Omega b(x) = \sum_{n \in \mathbb{Z}} \sum_{j \in \mathbb{Z}} T_j B_{j-n}. \]

Note that \( T_j B_{j-n}(x) = 0 \) if \( x \in (E^*)^c \) and \( n < 100 \). Therefore

\[
m \left( \{ x \in (E^*)^c : |T_\Omega b(x)| > \frac{\lambda}{2} \} \right) = m \left( \{ x \in (E^*)^c : \left| \sum_{n \geq 100} \sum_{j \in \mathbb{Z}} T_j B_{j-n}(x) \right| > \frac{\lambda}{2} \} \right).
\]

Hence, to finish the proof of Theorem 1.1, it suffices to verify the following estimate:

\[ m \left( \left\{ x \in (E^*)^c : \left| \sum_{n \geq 100} \sum_{j \in \mathbb{Z}} T_j B_{j-n}(x) \right| > \frac{\lambda}{2} \right\} \right) \lesssim \lambda^{-1} C_{\Omega} \| f \|_1. \] (2.4)

2.1. Some key estimates.

Some important estimates play key roles in the proof of (2.4). We present them by some lemmas, which will be proved in Section 3 and Section 4. The first estimate shows that the operator \( T_j \) can be approximated by an operator \( T_j^n \) in measure, which is defined below.

Let \( l_\delta(n) = [2\delta^{-1} \log_2 n] + 2 \). Here \([a]\) is the integer part of \( a \). Let \( \eta \) be a nonnegative, radial \( C_c^\infty \) function which is supported in \( \{|x| \leq 1\} \) and \( \int_{\mathbb{R}^d} \eta(x) dx = 1 \). Set \( \eta_i(x) = 2^{-id} \eta(2^{-i}x) \). Define

\[ K^n_j(x, y) = \int_{\mathbb{R}^d} \eta_{j-l_\delta(n)}(x - z)K_j(z, y)dz. \]

Notice that \( K_j(z, y) \) is supported in \( \{2^{j-1} \leq |z - y| \leq 2^{j+1}\} \) and \( \eta_{j-l_\delta(n)}(x) \) is supported in \( \{|x| \leq 2^{j-l_\delta(n)}\} \), so \( K^n_j(x, y) \) is supported in \( \{2^{j-2} \leq |x - y| \leq 2^{j+2}\} \). Therefore

\[ |K^n_j(x, y)| \lesssim 2^{-jd} \chi_{\{2^{j-2} \leq |x - y| \leq 2^{j+2}\}}. \] (2.5)

Define the operator \( T_j^n \) by

\[ T_j^n h(x) = \int_{\mathbb{R}^d} \Omega(x - y)K^n_j(x, y) \cdot h(y)dy. \]

Lemma 2.1. With the notations above, we have

\[ m \left( \left\{ x \in (E^*)^c : \sum_{n \geq 100} \left| \sum_j \left( T_j B_{j-n}(x) - T_j^n B_{j-n}(x) \right) \right| > \frac{\lambda}{4} \right\} \right) \lesssim \frac{1}{\lambda} \| \Omega \|_1 \| f \|_1. \]
By Lemma 2.1, the proof of \((2.3)\) now is reduced to verify the following estimate:

\[
(2.6) \quad m \left( \left\{ x \in (E^*)^c : \left| \sum_{n \geq 100} \sum_{j \in \mathbb{Z}} T^n_j B_{j-n}(x) \right| > \frac{\lambda}{2} \right\} \right) \lesssim \lambda^{-1} C_\Omega \|f\|_1.
\]

Our second lemma shows that, \((2.6)\) holds if \(\Omega\) is restricted in some subset of \(\mathbb{S}^{d-1}\). More precisely, for fixed \(n \geq 100\), denote \(D^i = \{ \theta \in \mathbb{S}^{d-1} : |\Omega(\theta)| \geq 2^n \|\Omega\|_1 \}\), where \(\iota > 0\) will be chosen later. The operator \(T^n_{j,k}\) is defined by

\[
T^n_{j,k}(x) = \int_{\mathbb{R}^d} \Omega(x-y) \left( \frac{x-y}{|x-y|} \right) K^n_j(x,y) \cdot h(y) dy.
\]

We have the following result.

**Lemma 2.2.** Under the conditions of Theorem 1.1, for \(f \in L^1(\mathbb{R}^d)\), we have

\[
m \left( \left\{ x \in (E^*)^c : \left| \sum_{n \geq 100} \sum_{j \in \mathbb{Z}} T^n_j B_{j-n}(x) \right| > \frac{\lambda}{\iota} \right\} \right) \lesssim C_\Omega \frac{\|f\|_1}{\iota}.
\]

Thus, by Lemma 2.2, to finish the proof of Theorem 1.1 it suffices to verify \((2.6)\) under the condition that the kernel function \(\Omega\) satisfies \(\|\Omega\|_\infty \leq 2^n \|\Omega\|_1\) in each \(T^n_j\).

In the following, we need to make a microlocal decomposition of the kernel. To do this, we give a partition of unity on the unit surface \(\mathbb{S}^{d-1}\). Choose \(n \geq 100\). Let \(\Theta_n = \{ e^n_v \}_v\) be a collection of unit vectors on \(\mathbb{S}^{d-1}\) which satisfies the following two conditions:

(a) \(|e^n_v - e^n_{v'}| \geq 2^{-n\gamma-4}\), if \(v \neq v'\);

(b) If \(\theta \in \mathbb{S}^{d-1}\), there exists an \(e^n_v\) such that \(|e^n_v - \theta| \leq 2^{-n\gamma-4}\).

The constant \(0 < \gamma < 1\) in (a) and (b) will be chosen later. To choose such an \(\Theta_n\), we may simply take a maximal collection \(\{ e^n_v \}_v\) for which (a) holds. Notice that there are \(C2^{2n\gamma(d-1)}\) elements in the collection \(\{ e^n_v \}_v\). For every \(\theta \in \mathbb{S}^{d-1}\), there only exists finite \(e^n_v\) such that \(|e^n_v - \theta| \leq 2^{-n\gamma-4}\).

Now we can construct an associated partition of unity on the unit surface \(\mathbb{S}^{d-1}\). Let \(\zeta\) be a smooth, nonnegative, radial function with \(\zeta(u) = 1\) for \(|u| \leq \frac{1}{2}\) and \(\zeta(u) = 0\) for \(|u| > 1\). Set

\[
\hat{\Gamma}_v^n(\xi) = \zeta \left( 2^{n\gamma} \frac{\xi}{|\xi|} - e^n_v \right)
\]

and define

\[
\Gamma_v^n(\xi) = \hat{\Gamma}_v^n(\xi) \left( \sum_{e^n_v \in \Theta_n} \hat{\Gamma}_v^n(\xi) \right)^{-1}.
\]

Then it is easy to see that \(\Gamma_v^n\) is homogeneous of degree 0 with

\[
\sum_v \Gamma_v^n(\xi) = 1, \text{ for all } \xi \neq 0 \text{ and all } n.
\]

Now we define operator \(T^n_{j,v}\) by

\[
(2.7) \quad T^n_{j,v}(x) = \int_{\mathbb{R}^d} \Omega(x-y) \Gamma_v^n(x-y) \cdot K^n_j(x,y) \cdot h(y) dy.
\]

Therefore, we have

\[
T^n_j = \sum_v T^n_{j,v}.
\]
In the sequel, we need to separate the phase into different directions. Hence we define a multiplier operator by

\[ \hat{G}_{n,v}(\xi) = \Phi(2^{n\gamma}\langle e_n^v, \xi/|\xi| \rangle) \hat{h}(\xi), \]

where \( h \) is a Schwartz function and \( \Phi \) is a smooth, nonnegative, radial function such that \( 0 \leq \Phi(x) \leq 1 \) and \( \Phi(x) = 0 \) on \( |x| \leq 2 \), \( \Phi(x) = 1 \) on \( |x| > 4 \). Now we can split \( T_{n,v}^n \) into two parts:

\[ T_{n,v}^n = G_{n,v}T_{n,v}^n + (I - G_{n,v})T_{n,v}^n. \]

The following lemma gives the \( L^2 \) estimate involving \( G_{n,v}T_{n,v}^n \), which will be proved in next section.

**Lemma 2.3.** Let \( n \geq 100 \). Suppose \( \|\Omega\|_\infty \leq 2^m\|\Omega\|_1 \) in \( T_n \), then we have the following estimate

\[ \left\| \sum_j \sum_v G_{n,v}T_{n,v}^n B_{j-n} \right\|_2^2 \lesssim 2^{-n\gamma+2n\nu} \lambda \|\Omega\|_1 \|f\|_1. \]

The terms involving \( (I - G_{n,v})T_{n,v}^n \) are more complicated. For convenience, we set \( L_{n,v} = (I - G_{n,v})T_{n,v}^n \). In Section 4, we shall prove the following lemma.

**Lemma 2.4.** Suppose \( \|\Omega\|_\infty \leq 2^m\|\Omega\|_1 \) in \( T_n \). With the notations above, we have

\[ m\left( \left\{ x \in (E^*)^c : \left( \sum_{n \geq 100} \sum_j \sum_v L_{n,v}^n B_{j-n}(x) \right) > \frac{\lambda}{8} \right\} \right) \lesssim \lambda^{-1} \|\Omega\|_1 \|f\|_1. \]

### 2.2. Proof of (2.6).

We now complete the proof of (2.6) under the condition \( \|\Omega\|_\infty \leq 2^m\|\Omega\|_1 \) in each \( T_n \). By Chebyshev’s inequality,

\[ m\left( \left\{ x \in (E^*)^c : \left( \sum_{n \geq 100} \sum_j L_{n,v}^n B_{j-n}(x) \right) > \frac{\lambda}{4} \right\} \right) \]

\[ \lesssim \lambda^{-2} \left\| \sum_{n \geq 100} \sum_j \sum_v G_{n,v}T_{n,v}^n B_{j-n} \right\|_2^2 \]

\[ + m\left( \left\{ x \in (E^*)^c : \left( \sum_{n \geq 100} \sum_j \sum_v L_{n,v}^n B_{j-n}(x) \right) > \frac{\lambda}{8} \right\} \right) \]

\[ =: I + II. \]

Using Lemma 2.4 we can get the desired estimate of \( II \). Next we consider the term \( I \). Choose \( 0 < \nu < \frac{\gamma}{2} \). Minkowski’s inequality and Lemma 2.3 implies

\[ I \lesssim \lambda^{-2} \left( \sum_{n \geq 100} \left\| \sum_j \sum_v G_{n,v}T_{n,v}^n B_{j-n} \right\|_2 \right)^2 \]

\[ \lesssim \lambda^{-2} \left( \sum_{n \geq 100} (2^{-n\gamma+2n\nu} \|\Omega\|_1 \|f\|_1)^{\frac{1}{2}} \right)^2 \lesssim \lambda^{-1} \|\Omega\|_1 \|f\|_1. \]

We hence complete the proof of Theorem 1.1 once Lemmas 2.1-2.4 hold.
3. PROOFS OF LEMMAS 2.1-2.3

3.1. Proof of Lemma 2.1

We first focus on the proof of Lemma 2.1. By the definitions of $T_j$ and $T_j^n$, we have

$$
\|T_j f - T_j^n f\|_1 = \int_{\mathbb{R}^d} \left| \int_{\mathbb{R}^d} \Omega(x-y)(K_j(x,y) - K_j^n(x,y))f(y)dy \right| dx
$$

By the definition of $K_j(x,y)$, we have

$$
|K_j(x,y) - K_j(x,z,y)| \leq |\phi_j(x-y)(K(x,y) - K(x-z,y))| + |\phi_j(x-y) - \phi_j(x-z-y)||K(x-z,y)|.
$$

Consider the first term firstly. Note that $|z| \leq 2^{j-l}\lambda(n)$ and $2^{j-1} \leq |x-y| \leq 2^{j+1}$, then we have $2|z| < |x-y|$. By the regularity condition (1.9), the first term above is bounded by

$$
\frac{|z|^d}{|x-y|^{d+\delta}} |\chi_{\{2^{j-1} \leq |x-y| \leq 2^{j+1}\}}| \lesssim n^{-2} 2^{-jd} \chi_{\{2^{j-1} \leq |x-y| \leq 2^{j+1}\}}.
$$

We turn to the second term. By the fact $|z| \leq 2^{j-l}\lambda(n)$ and the support of $\phi_j$, we have $|x-y| \approx |x-z-y|$ and $2^{j-2} \leq |x-y| \leq 2^{j+2}$. By (1.8), the second term is controlled by

$$
\frac{2^{-j}|z|}{|x-z-y|^{d+\delta}} |\chi_{\{2^{j-2} \leq |x-y| \leq 2^{j+2}\}}| \lesssim n^{-2} 2^{-jd} \chi_{\{2^{j-2} \leq |x-y| \leq 2^{j+2}\}}.
$$

Combining the above two estimates and applying Minkowski’s inequality, we get

$$
\|T_j f - T_j^n f\|_1 \lesssim n^{-2} \int_{\mathbb{R}^d} \int_{|x-y| \leq 2^{j+1}} 2^{-jd} |\Omega(x-y)| \int_{\mathbb{R}^d} \eta_{j-l}(n) |z| dz |f(y)| dy dx
$$

$$
\lesssim n^{-2} 2^{-jd} \int_{\mathbb{R}^d} \int_{|x-y| \leq 2^{j+2}} |\Omega(x-y)| dx |f(y)| dy
$$

$$
\lesssim n^{-2} \|\Omega\|_1 \|f\|_1.
$$

By Chebyshev’s inequality, Minkowski’s inequality and the estimates above, we get the bound

$$
m\left( \left\{ x \in (E^*)^c : \sum_{n \geq 100} \sum_j T_j B_{j-n}(x) - T_j^n B_{j-n}(x) > \frac{\lambda}{4} \right\} \right)
$$

$$
\lesssim \lambda^{-1} \|\Omega\|_1 \sum_{n \geq 100} \sum_j \|T_j B_{j-n} - T_j^n B_{j-n}\|_1
$$

$$
\lesssim \lambda^{-1} \|\Omega\|_1 \sum_{n \geq 100} n^{-2} \sum_j \|B_{j-n}\|_1 \lesssim \lambda^{-1} \|\Omega\|_1 \|f\|_1,
$$

which is the required estimate. $\square$

3.2. Proof of Lemma 2.2

Denote the kernel of the operator $T_{j,t}^n$ by

$$
K_{j,t}^n(x,y) := \Omega \chi_D \left( \frac{x-y}{|x-y|} \right) K_j^n(x,y).
$$
By (2.3), we have
\[
\left| \int_{\mathbb{R}^d} K_{j,t}^n(x,y)dy \right| \lesssim \int_{D^t} \int_{2j-2}^{2j+2} |\Omega(\theta)|r^{d-1}2^{-jd}drd\theta \lesssim \int_{D^t} |\Omega(\theta)|d\theta.
\]
Therefore by Chebyshev’s inequality, the above inequality, the property (cz-v), we get
\[
m\left( \left\{ x \in (E^*)^c : \left| \sum_{n \geq 100} \sum_{j \in \mathbb{Z}} T_{j,n}^n B_{j-n}(x) \right| > \frac{\lambda}{8} \right\} \right) 
\lesssim \lambda^{-1} \left\| \sum_{n \geq 100} \sum_{j \in \mathbb{Z}} T_{j,n}^n B_{j-n} \right\|_1 
\lesssim \lambda^{-1} \sum_{n \geq 100} \sum_{j} \|B_{j-n}\|_1 \int_{D^t} |\Omega(\theta)|d\theta 
\lesssim \lambda^{-1} \|b\|_1 \int_{\mathbb{S}^{d-1}} \text{card}\{ n \in \mathbb{N} : n \geq 100, 2^n \leq |\Omega(\theta)|/\|\Omega\|_1 \} |\Omega(\theta)|d\theta 
\lesssim \lambda^{-1} \|f\|_1 \int_{\mathbb{S}^{d-1}} |\Omega(\theta)|(1 + \log^+ (|\Omega|/\|\Omega\|_1))d\theta 
\lesssim \lambda^{-1} C\Omega \|f\|_1.
\]
3.3. Proof of Lemma 2.3

We will use some ideas from [29] in the proof of Lemma 2.3. As usually, we adopt the TT* method in the $L^2$ estimate. Moreover, we need to use some orthogonality argument based on the following observation of the support of $\mathcal{F}(G_{n,t}T_{j}^{n,v})$: For a fixed $n \geq 100$, we have
\[
\sup_{\xi \neq 0} \sum_v |\Phi(2^{n\gamma} \langle e_v^n, \xi/|\xi| \rangle)| \lesssim 2^{n\gamma(d-2)}.
\]
In fact, by homogeneous of $\Phi(2^{n\gamma} \langle e_v^n, \xi/|\xi| \rangle)$, it suffices to take the supremum over the surface $\mathbb{S}^{d-1}$. For $|\xi| = 1$ and $\xi \in \text{supp} \; \Phi(2^{n\gamma} \langle e_v^n, \xi/|\xi| \rangle)$, denote by $\xi^\perp$ the hyperplane perpendicular to $\xi$. Thus
\[
\text{dist}(e_v^n, \xi^\perp) \lesssim 2^{-n\gamma}.
\]
Since the mutual distance of $e_v^n$s is bounded by $2^{-n\gamma-4}$, there are at most $2^{n\gamma(d-2)}$ vectors satisfy (3.2). We hence get (3.1).

By applying Plancherel’s theorem and Cauchy-Schwarz inequality, we have
\[
\left\| \sum_v \sum_j G_{n,v} T_{j, n}^v B_{j-n} \right\|_2^2 = \left\| \sum_v \Phi(2^{n\gamma} \langle e_v^n, \xi/|\xi| \rangle) \mathcal{F}\left( \sum_j T_{j, n}^v B_{j-n} \right)(\xi) \right\|_2^2 
\lesssim 2^{n\gamma(d-2)} \left\| \sum_v \left| \mathcal{F}\left( \sum_j T_{j, n}^v B_{j-n} \right) \right| \right\|_1 
\lesssim 2^{n\gamma(d-2)} \sum_v \left\| \sum_j T_{j, n}^v B_{j-n} \right\|_2^2.
\]
Once it is shown that for a fixed $e_v^n$,
\[
\left\| \sum_j T_{j, n}^v B_{j-n} \right\|_2^2 \lesssim 2^{-2n\gamma(d-1)+2n\lambda} \|\Omega\|_1 \|f\|_1,
\]
(3.4)
then by card(Θn) ≲ 2nγ(d−1), and apply (3.3) and (3.4) we get
\[
\left\| \sum_{j=1}^{\infty} T^v_j B_{j-n} \right\|_2 \leq 2^{-n\gamma(d-1)-\gamma+2n\epsilon} \text{card}(\Theta_n) \lambda \Omega_1 \|f\|_1 \lesssim 2^{-n\gamma+2n\epsilon} \Omega_1 \|f\|_1,
\]
which is just the desired bound of Lemma 2.3. Thus, to finish the proof of Lemma 2.3, it is enough to prove (3.3). By applying \|\Omega\|_\infty \leq 2^m \|\Omega\|_1, (2.5) and the support of \Gamma^n, we have
\[
|T^v_j B_{j-n}(x)| \lesssim 2^n \|\Omega\|_1 \int_{\mathbb{R}^d} \Gamma^n(x-y) |K^v_j(x,y)||B_{j-n}(y)|dy \lesssim 2^n \|\Omega\|_1 B^v_j \cdot |B_{j-n}(x)|,
\]
where \(H^v_j(x) := 2^{-jd} \chi_{E^v_j}(x)\) and \(\chi_{E^v_j}(x)\) is a characteristic function of the set
\[
E^v_j := \{x \in \mathbb{R}^d : \langle x, e^n_v \rangle \leq 2j^2+2, |x - \langle x, e^n_v \rangle| \leq 2^{j+2-n\gamma}\}.
\]
For a fixed \(e^n_v\), we write
\[
\left\| \sum_j T^v_j B_{j-n} \right\|_2^2 \leq 2^{2n} \|\Omega\|_1^2 \sum_j \int_{\mathbb{R}^d} H^v_j \ast H^v_j \ast |B_{j-n}(x) \cdot B_{j-n}(x)| dx
\]
\[
2^{2n+1} \|\Omega\|_1^2 \sum_i \sum_{j=-\infty}^{j-1} \int_{\mathbb{R}^d} H^v_j \ast H^v_i \ast |B_{i-n}(x) \cdot B_{j-n}(x)| dx.
\]
Observe that \(\|H^v_i\|_1 \lesssim 2^{-id} m(E^v_i) \lesssim 2^{-n\gamma(d-1)}\), therefore for any \(i \leq j\),
\[
H^v_j \ast H^v_i \ast (x) \lesssim 2^{-n\gamma(d-1)} 2^{-jd} \chi_{E^v_j},
\]
where \(\tilde{E}^v_j = E^v_j + E^v_j\). Hence for a fixed \(j, n, e^n_v\) and \(x\), we have
\[
H^v_j \ast H^v_i \ast |B_{i-n}(x)| + 2 \sum_{i=-\infty}^{j-1} H^v_j \ast H^v_i \ast |B_{i-n}(x)|
\]
\[
\lesssim 2^{-n\gamma(d-1)} 2^{-jd} \sum_{i \leq j} \int_{\mathbb{R}^d} |b_Q(y)|dy \lesssim 2^{-n\gamma(d-1)} 2^{-jd} \sum_{Q \in \Omega_v} \sum_{Q \cap \tilde{E}^v_j \neq \emptyset} \lambda \frac{1}{C} |Q| 
\]
\[
\lesssim 2^{-n\gamma(d-1)} 2^{-jd} \sum_{i \leq j} \sum_{Q \in \Omega_v} \sum_{Q \cap \tilde{E}^v_j \neq \emptyset} \frac{\lambda}{\Omega_v} |Q| 
\]
\[
\lesssim 2^{-n\gamma(d-1)} 2^{-jd} \lambda 2^{-n\gamma(d-1)} \frac{\lambda}{\Omega_v} = 2^{-2n\gamma(d-1)} \frac{\lambda}{\Omega_v},
\]
where in third inequality above, we use \(\int |b_Q(y)|dy \lesssim \lambda |Q|/C\Omega\) (see (cz-v) in Section 2) and in the fourth inequality we use fact that the cubes in \(Q\) are disjoint (see (cz-iii) in Section 2). By (3.5), (3.6) and \(\sum_j \|B_{j-n}\|_1 \lesssim \|f\|_1\), we obtain
\[
\left\| \sum_j T^v_j B_{j-n} \right\|_2^2 \lesssim 2^{-2n\gamma(d-1)+2n \epsilon} \Omega_1 \sum_j \|B_{j-n}\|_1 \lesssim 2^{-2n\gamma(d-1)+2n \epsilon} \Omega_1 \|f\|_1.
\]
Hence, we complete the proof of Lemma 2.3.

4. Proof of Lemma 2.4

To prove Lemma 2.4, we have to face with some oscillatory integrals which come from $L_{j,v}^{n,v}$. We first introduce Mihlin multiplier theorem, which can be found in [19].

**Lemma 4.1.** Let $m$ be a complex-value bounded function on $\mathbb{R}^n \setminus \{0\}$ that satisfies

$$|\partial_\alpha^\xi m(\xi)| \leq A|\xi|^{-|\alpha|}$$

for all multi indices $|\alpha| \leq \lfloor d/2 \rfloor + 1$, then the operator $T_m$ defined by

$$\hat{T}_m f(\xi) = m(\xi) \hat{f}(\xi)$$

is a weak type $(1,1)$ bounded operator with bound $C_d(A + \|m\|_\infty)$.

Before stating the proof of Lemma 2.4, let us give some notations. We first introduce the Littlewood-Paley decomposition. Let $\psi$ be a radial $C^\infty$ function such that $\psi(\xi) = 1$ for $|\xi| \leq 1$, $\psi(\xi) = 0$ for $|\xi| \geq 2$ and $0 \leq \psi(\xi) \leq 1$ for all $\xi \in \mathbb{R}^d$. Define $\beta_k(\xi) = \psi(2^k \xi) - \psi(2^{k+1} \xi)$, then $\beta_k$ is supported in $\{\xi : 2^{-k-1} \leq |\xi| \leq 2^{-k+1}\}$. Define the convolution operators $V_k$ and $\Lambda_k$ with Fourier multipliers $\psi(2^k \cdot)$ and $\beta_k$, respectively. That is,

$$\hat{V}_k f(\xi) = \psi(2^k \xi) \hat{f}(\xi), \quad \hat{\Lambda}_k f(\xi) = \beta_k(\xi) \hat{f}(\xi).$$

Then by the construction of $\beta_k$ and $\psi$, we have

$$I = \sum_{k \in \mathbb{Z}} \Lambda_k = V_m + \sum_{k < m} \Lambda_k \quad \text{for every } m \in \mathbb{Z}. $$

Set $A_{j,m}^{n,v} = V_m T_j^{n,v}$ and $D_{j,k}^{n,v} = (I - G_{n,v}) \Lambda_k T_j^{n,v}$. Write

$$L_j^{n,v} = (I - G_{n,v})V_m T_j^{n,v} + \sum_{k < m} (I - G_{n,v}) \Lambda_k T_j^{n,v}$$

$$=: (I - G_{n,v})A_{j,m}^{n,v} + \sum_{k < m} D_{j,k}^{n,v},$$

where $m = j - [n \varepsilon_0]$, $\varepsilon_0 > 0$ will be chosen later. To prove Lemma 2.4, we split the measure in Lemma 2.4 into two parts,

$$m\left(\left\{ x \in (E^*)^c : \left| \sum_{n \geq 100} v \sum_j (I - G_{n,v}) T_j^{n,v} B_{j-n}(x) \right| > \lambda \right\}\right)$$

$$\leq m\left(\left\{ x \in (E^*)^c : \left| \sum_{n \geq 100} v \sum_j (I - G_{n,v}) \left(\sum_j A_{j,m}^{n,v} B_{j-n}(x)\right) \right| > \lambda \right\}\right)$$

$$+ m\left(\left\{ x \in (E^*)^c : \left| \sum_{n \geq 100} v \sum_j \sum_{k < m} D_{j,k}^{n,v} B_{j-n}(x) \right| > \lambda \right\}\right)$$

$$=: I + II.$$
4.1. First step: basic estimates of \( I \) and \( II \).

Consider the term \( I \). Notice that \( \mathcal{F}[(I - G_{n,v})f](\xi) = (1 - \Phi(2^{n \gamma} \langle e_v^n, \xi/|\xi| \rangle)) \cdot f(\xi) \). It is easy to see that \( (1 - \Phi(2^{n \gamma} \langle e_v^n, \xi/|\xi| \rangle)) \) is bounded and

\[
|\partial^\alpha (1 - \Phi(2^{n \gamma} \langle e_v^n, \xi/|\xi| \rangle))| \lesssim 2^{n \gamma (|\alpha|/2) + 1}|\xi|^{-|\alpha|}
\]

for all multi indices \(|\alpha| \leq (n \gamma)/2) + 1\). Then by Lemma 4.1, \( I - G_{n,v} \) is of weak type \((1,1)\) bounded with \(2^{n \gamma (|\alpha|/2) + 1}\). By using the pigeonhole principle, one may get

\[
\{x : \sum_i f_i(x) > \sum_i \lambda_i\} \subseteq \bigcup_i \{x : f_i(x) > \lambda_i\}.
\]

Let \( \mu > 0 \) be chosen later. Then there exists \( C_{\mu,d} \) such that

\[
\sum_{n \geq 100} \sum_{\varepsilon_v^n \in \Theta_n} C_{\mu,d} 2^{-n \mu - n \gamma(d-1)} = \frac{1}{2}.
\]

Therefore

\[
m \left( \{x \in (E^*)^c : \left| \sum_{n \geq 100} \sum_v (I - G_{n,v}) \left( \sum_j A_{j,m}^{n,v} B_{j,n} \right)(x) \right| > \frac{\lambda}{2} \} \right)
\]

\[
= m \left( \{x \in (E^*)^c : \left| \sum_{n \geq 100} \sum_v (I - G_{n,v}) \left( \sum_j A_{j,m}^{n,v} B_{j,n} \right)(x) \right| > \sum_{n \geq 100} \sum_v C_{\mu,d} 2^{-n \mu - n \gamma(d-1)} \lambda \} \right)
\]

\[
\leq \sum_{n \geq 100} \sum_v m \left( \{x \in (E^*)^c : \left| (I - G_{n,v}) \left( \sum_j A_{j,m}^{n,v} B_{j,n} \right)(x) \right| > C_{\mu,d} 2^{-n \mu - n \gamma(d-1)} \lambda \} \right)
\]

\[
\leq \sum_{n \geq 100} \sum_v \sum_j \sum_{l(Q) = 2^{j-n}} \frac{1}{C_{\mu,d} \lambda} 2^{n \mu + n \gamma(d-1) + n \gamma(|\alpha|/2) + 1} \|A_{j,m}^{n,v} B_{j,n} \|_1
\]

where the second inequality follows from (4.2) and in the third inequality we use \( I - G_{n,v} \) is weak type \((1,1)\) bounded and Minkowski’s inequality.

Next we turn to the term \( II \). We use \( L^1 \) estimate directly

\[
II \leq \frac{2}{\lambda} \sum_{n \geq 100} \sum_v \sum_j \sum_{k < m} \sum_{l(Q) = 2^{j-n}} \|D_{j,k}^{n,v} b_Q \|_1 \leq \frac{2}{\lambda} \sum_{n \geq 100} \sum_v \sum_j \sum_{k < m} \sum_{l(Q) = 2^{j-n}} \|D_{j,k}^{n,v} b_Q \|_1.
\]

Now the problem is reduced to estimate \( \|A_{j,m}^{n,v} b_Q \|_1 \) and \( \|D_{j,k}^{n,v} b_Q \|_1 \). Recall in (2.7), the kernel of operator \( T_{j}^{n,v} \) is

\[
K_{j,n}^{n,v}(x) := \Omega(x - y) \Gamma^n_v (x - y) K_{j}^n(x, y).
\]

Below we see \( K_{j,n}^{n,v}(x) \) as a function of \( x \) for a fixed \( y \in Q \). Thus, by Fubini’s theorem,

\[
A_{j,m}^{n,v} b_Q(x) = \int_Q V_m K_{j,n}^{n,v}(x) \cdot b_Q(y) dy =: \int_Q A_m(x, y) b_Q(y) dy
\]

and

\[
D_{j,k}^{n,v} b_Q(x) = \int_Q (I - G_{n,v}) \Lambda_k K_{j,n}^{n,v}(x) \cdot b_Q(y) dy =: \int_Q D_k(x, y) b_Q(y) dy.
\]
4.2. Estimate of $D_k$.

**Lemma 4.2.** For a fixed $y \in Q$, there exists $N > 0$, such that for any $N_1 \in \mathbb{Z}_+$

\begin{equation}
\|D_k(\cdot, y)\|_1 \leq C n^{2d-1} N_1 2^{-n\gamma(d-1)+n\eta(2(-j+k))} N_1 + n\eta(N_1 + 2^N) \|\Omega\|_1,
\end{equation}

where $C$ is a constant independent of $y$, but may depend on $N_1$, $N$ and $d$.

**Proof.** Denote $h_{k,n,v}(\xi) = (1 - \Phi(2^{n\gamma} e_v(\xi/|\xi|))) \beta_k(\xi)$. Write $D_k(x, y)$ as

\begin{equation}
(I - G_{n,v}) \Lambda_k K_{j,y}^{n,v}(x) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} e^{i\xi \cdot x} h_{k,n,v}(\xi) \int_{\mathbb{R}^d} e^{-i\xi \cdot \omega} \Omega(\omega - y) \Gamma_v^n(\omega - y) K_j^n(\omega, y) d\omega d\xi.
\end{equation}

In order to separate the rough kernel, we make a variable change $\omega - y = r\theta$. By Fubini’s theorem, the integral above can be written as

\begin{equation}
\frac{1}{(2\pi)^d} \int_{\mathbb{S}^{d-1}} \Omega(\theta) \Gamma_v^n(\theta) \left\{ \int_{\mathbb{R}^d} \int_0^\infty e^{i(x-y-r\theta,\xi)} h_{k,n,v}(\xi) K_j^n(\omega + r\theta, y) r^{d-1} dr d\xi \right\} d\theta.
\end{equation}

By the support of $K_j^n(x, y)$ in (2.5), we have $2^{j-2} \leq r \leq 2^{j+2}$. Integrate by parts $N_1$ times with $r$. Hence the integral involving $r$ can be rewritten as

\begin{equation}
\int_0^\infty e^{i(x-y-r\theta,\xi)} (i\langle \theta, \xi \rangle)^{-N_1} \|\xi\|^{-1} d\xi.
\end{equation}

Since $\theta \in \text{supp } \Gamma^n_v$, then $|\theta - e^n_v| \leq 2^{-n\gamma}$. By the support of $\Phi$, we see $|\langle e^n_v, \xi/|\xi| \rangle| \geq 2^{1-nr}$. Thus

\begin{equation}
|\langle \theta, \xi/|\xi| \rangle| \geq |\langle e^n_v, \xi/|\xi| \rangle| - |\langle e^n_v - \theta, \xi/|\xi| \rangle| \geq 2^{-n\gamma}.
\end{equation}

After integrating by parts with $r$, integrate by parts with $\xi$, the integral in (4.6) can be rewritten as

\begin{equation}
\frac{1}{(2\pi)^d} \int_{\mathbb{S}^{d-1}} \Omega(\theta) \Gamma_v^n(\theta) \left\{ \int_{\mathbb{R}^d} \int_0^\infty e^{i(x-y-r\theta,\xi)} \partial_r^{N_1} \left( K_j^n(y + r\theta, y) r^{d-1} \right) \times \right.
\end{equation}

\begin{equation}
\frac{(I - 2^{-2k} \Delta^N\xi)_N}{(1 + 2^{-2k}|x - y - r\theta|^2)_N} (h_{k,n,v}(\xi) (i\langle \theta, \xi \rangle)^{-N_1}) dr d\xi d\theta.
\end{equation}

In the following, we give an explicit estimate of the term in (4.8). By the definition of $K_j^n(x, y)$, we have

\begin{equation}
|\partial_x^a K_j^n(x, y)| = 2^{-|-(j-l_a(n))|} \left| \int (\partial_x^a \eta)_{j-l_a(n)}(x - z) K_j(z, y) dz \right|
\end{equation}

\begin{equation}
\leq 2^{-|-(j-l_a(n))|} \|K_j(\cdot, y)\|_1 \|\partial_x^a \eta\|_1
\end{equation}

\begin{equation}
\leq 2^{-|-(j-l_a(n))|} \theta_j d,
\end{equation}

where the third inequality follows from (2.5). By using product rule,

\begin{equation}
\left| \partial_r^{N_1} \left( K_j(y + r\theta, y) r^{d-1} \right) \right| = \left| \sum_{i=0}^{N_1} C_i^{N_1} \partial_r^i \left( K_j^n(y + r\theta, y) \right) \partial_r^{N_1-i} (r^{d-1}) \right|
\end{equation}

\begin{equation}
= \left| \sum_{i=N_1-d+1}^{N_1} C_i^{N_1} \partial_r^i \left( K_j^n(y + r\theta, y) \right) \partial_r^{N_1-i} (r^{d-1}) \right|.
\end{equation}
Applying (4.9) and $2^{j-2} \leq r \leq 2^{j+2}$, the above (4.10) is bounded by

$$
\sum_{i=N_1-d+1}^{N_1} C_{N_1}^i 2^{-(j-l_0(n))i-jd2(j+2)(d-1-N_1+i)} \leq C_{N_1} n^{2\delta - 1} N_1 2^{-(1+N_1)}.
$$

(4.11)

Below we will show that

$$
|\langle \partial_n \theta, \xi \rangle^{-N_1} h_{k,n,v}(\xi)| \leq \langle \theta, \xi \rangle^{-N_1} \lesssim 2^{(n\gamma+k)N_1}.
$$

We prove (4.12) when $N = 0$ firstly. By (4.7), we have

$$
|\left( -i \langle \theta, \xi \rangle \right)^{N_1} h_{k,n,v}(\xi)| \lesssim |\langle \theta, \xi \rangle |^{-N_1} \lesssim 2^{(n\gamma+k)N_1}.
$$

By using product rule,

$$
|\partial_\xi h_{k,n,v}(\xi)| = \left| -\partial_\xi [\Phi(2^{n\gamma} (e_{\nu_0}, \Omega/|\xi|))] \cdot \beta_k(\xi) + \partial_\xi \theta_k(\xi) \cdot (1 - \Phi(2^{n\gamma} (e_{\nu_0}, \Omega/|\xi|))) \right| \lesssim 2^{n\gamma+k}.
$$

Therefore by induction, we have $|\partial_\xi^2 h_{k,n,v}(\xi)| \lesssim 2^{(n\gamma+k)|\alpha|}$ for any multi-indices $\alpha \in \mathbb{Z}_+^n$. By using product rule again and (4.7), we have

$$
|\partial_\xi^2 \langle \theta, \xi \rangle^{-N_1} h_{k,n,v}(\xi) | = |\langle \theta, \xi \rangle^{-N_1-2} \cdot \frac{1}{N_1(N_1+1)} \partial_\xi \theta_k h_{k,n,v} + 2 \langle \theta, \xi \rangle^{-N_1-1} \cdot \partial_i \partial_\xi \theta_k h_{k,n,v}(\xi) + \langle \theta, \xi \rangle^{-N_1} \partial_\xi^2 h_{k,n,v}(\xi)|
$$

$$
\leq C_{N_1} 2^{(n\gamma+k)(N_1+2)}.
$$

Hence we conclude that

$$
2^{-2k} |\Delta_j \langle \theta, \xi \rangle^{-N_1} h_{k,n,v}(\xi)| \leq C_{N_1} 2^{(n\gamma+k)N_1+2\gamma}.
$$

(4.12)

Proceeding by induction, we get (4.12).

Now we choose $N = [d/2] + 1$. Since we need to get the $L^1$ estimate of (4.6), by the support of $h_{k,n,v}$,

$$
\int_{\text{supp}(h_{k,n,v})} \int \left( 1 + 2^{-2k|x-y-r\theta|^2} \right)^{-N} dx d\xi \leq C.
$$

Integrating with $r$, we get a bound $2^j$. Note that we suppose that $\|\Omega\|_\infty \leq 2^{m} \|\Omega\|_1$. Then integrating with $\theta$, we get a bound $2^{-\gamma(d-1)+m} \|\Omega\|_1$. Combining (4.11), (4.12) and above estimates, $\|D_k(\cdot, y)\|_1$ is bounded by

$$
C_{N_1} n^{2\delta - 1} N_1 2^{-j(1+N_1)+(n\gamma+k)N_1+2n\gamma N+j-n\gamma(d-1)+n\gamma} \|\Omega\|_1
$$

$$
= C_{N_1} n^{2\delta - 1} N_1 2^{-\gamma(d-1)+m} 2^{-j+k} N_1 + n\gamma(N_1+2N) \|\Omega\|_1.
$$

Hence we complete the proof of Lemma 4.2 with $N = [d/2] + 1$. □
4.3. Estimate of $A_m$.

Using the cancellation condition of $b_Q$ (see (cz-v) in Section 2), we have

$$A_{j,m}^{n,v} b_Q(x) = \int_Q (A_m(x,y) - A_m(x,y_0)) b_Q(y) dy,$$

where $y_0$ is the center of $Q$. By changing to polar coordinates and applying Fubini’s theorem, we can write $A_m(x,y)$ as

$$\frac{1}{(2\pi)^d} \int_{S^{d-1}} \Omega(\theta) \Gamma_v^n(\theta) \left\{ \int_0^\infty \int_{\mathbb{R}^d} e^{i(x-y-r\theta,\xi)} \psi(2^n \xi) K_j^n(y+r\theta,y) r^{d-1} dr d\xi \right\} d\theta.$$

Integrating by part $N = [d/2] + 1$ times with $\xi$ in the above integral, we have

$$\frac{1}{(2\pi)^d} \int_{S^{d-1}} \Omega(\theta) \Gamma_v^n(\theta) \left\{ \int_0^\infty \int_{\mathbb{R}^d} e^{i(x-y-r\theta,\xi)} K_j^n(y+r\theta,y) r^{d-1} \right. \times \left. \frac{(I - 2^{-2m} \Delta^2)^N \psi(2^m \xi)}{(1 + 2^{-2m}|x - y - r\theta|^2)^N} d\xi dr \right\} d\theta.$$

Denote

$$A_m(x,y) = A_m(x,y_0) =: F_{m,1}(x,y) + F_{m,2}(x,y) + F_{m,3}(x,y),$$

where

$$F_{m,1}(x,y) = \frac{1}{(2\pi)^d} \int_{S^{d-1}} \Omega(\theta) \Gamma_v^n(\theta) \left\{ \int_0^\infty \int_{\mathbb{R}^d} e^{i(x-y,\xi)} - e^{i(y,\xi)} e^{i(x-y,\xi)} \right. \times \left. K_j^n(y+r\theta,y) r^{d-1} \frac{(I - 2^{-2m} \Delta^2)^N \psi(2^m \xi)}{(1 + 2^{-2m}|x - y - r\theta|^2)^N} d\xi dr \right\} d\theta,$$

$$F_{m,2}(x,y) = \frac{1}{(2\pi)^d} \int_{S^{d-1}} \Omega(\theta) \Gamma_v^n(\theta) \left\{ \int_0^\infty \int_{\mathbb{R}^d} e^{i(x-y-r\theta,\xi)} \left(K_j^n(y+r\theta,y) - K_j^n(y_0 + r\theta,y_0) \right) \right. \times \left. r^{d-1} \frac{(I - 2^{-2m} \Delta^2)^N \psi(2^m \xi)}{(1 + 2^{-2m}|x - y - r\theta|^2)^N} d\xi dr \right\} d\theta,$$

and

$$F_{m,3}(x,y) = \frac{1}{(2\pi)^d} \int_{S^{d-1}} \Omega(\theta) \Gamma_v^n(\theta) \int_0^\infty \int_{\mathbb{R}^d} e^{i(x-y-\theta,\xi)} (I - 2^{-2m} \Delta^2)^N \psi(2^m \xi) r^{d-1} \times \left. K_j^n(y_0 + r\theta,y_0) \frac{1}{(1 + 2^{-2m}|x - y - r\theta|^2)^N} - \frac{1}{(1 + 2^{-2m}|x - y_0 - r\theta|^2)^N} \right) d\xi dr d\theta.$$

Hence

$$(4.13) \quad \|A_{j,m}^{n,v} b_Q\|_1 \leq \sup_{y \in Q} (\|F_{m,1}(\cdot,y)\|_1 + \|F_{m,2}(\cdot,y)\|_1 + \|F_{m,3}(\cdot,y)\|_1) \|b_Q\|_1.$$

We have the following estimates of $F_{m,1}(x,y)$, $F_{m,2}(x,y)$, $F_{m,3}(x,y)$.

**Lemma 4.3.** For a fixed $y \in Q$, we have

$$\|F_{m,1}(\cdot,y)\|_1 \leq C 2^{-n\gamma(d-1)+n\epsilon+j-n-m} \|\Omega\|_1,$$

where $C$ is independent of $y$. 
Proof. We use the same method in proving Lemma 4.2 but don’t apply integrating by parts. Note that \( y \in Q \) and \( y_0 \) is the center of \( Q \), then \( |y - y_0| \lesssim 2^{j-n} \). Thus
\[
|e^{i(y,y,\xi)} - e^{i(y,y,\xi)}| \lesssim 2^{j-n-m}.
\]
Since \( 2^{j-2} \leq r \leq 2^{j+2} \) and \([2.5]\), we have \( |K^m(y + r\theta, y)r^{d-1}| \lesssim 2^{-j} \). It is easy to see that
\[
|(I - 2^{-2m}\Delta \xi)^N\psi(2^m \xi)| \leq C.
\]
Since we need to get the \( L^1 \) estimate of \( F_{m,1}(\cdot,y) \), by the support of \( \psi(2^m \xi) \), we have
\[
\int_{|\xi| \leq 2^{1-m}} \int \left( 1 + 2^{-2m}|x - y - r\theta|^2 \right)^{-N} d\xi \leq C.
\]
Integrating with \( r \), we get a bound \( 2^j \). Note that we suppose that \( \|\Omega\|_\infty \leq 2^n \|\Omega\|_1 \), so integrating with \( \theta \), we get a bound \( 2^{-n\gamma(d-1)+n} \|\Omega\|_1 \). Combining these bounds, we can get the required estimate for \( F_{m,1}(\cdot,y) \).

**Lemma 4.4.** For a fixed \( y \in Q \), we have
\[
\|F_{m,3}(\cdot,y)\|_1 \leq C2^{-n\gamma(d-1)+n+j-n-m} \|\Omega\|_1,
\]
where \( C \) is independent of \( y \).

Proof. For the term \( F_{m,3}(\cdot,y) \), we can deal with it in the same way as \( F_{m,1}(\cdot,y) \) once we have the following observation
\[
\left| \Psi(y) - \Psi(y_0) \right| = \left| \int_0^1 \left( y - y_0, \nabla\Psi(ty + (1-t)y_0) \right) dt \right|
\lesssim |y - y_0| 2^{-m} \int_0^1 \frac{N2^{-m}|x - (ty + (1-t)y_0) - r\theta|}{(1 + 2^{-2m}|x - (ty + (1-t)y_0) - r\theta|^2)^{N+1}} dt
\]
where \( \Psi(y) = (1 + 2^{-2m}|x - y - r\theta|^2)^{-N} \). Since \( y \in Q \) and \( y_0 \) is the center of \( Q \), we have \( |y - y_0| \lesssim 2^{j-n} \). By \( 2^{j-2} \leq r \leq 2^{j+2} \) and \([2.5]\), we have \( |K^m(y + r\theta, y)r^{d-1}| \lesssim 2^{-j} \). It is easy to see
\[
|(I - 2^{-2m}\Delta \xi)^N\psi(2^m \xi)| \leq C.
\]
Since we need to get the \( L^1 \) estimate of \( F_{m,3}(\cdot,y) \), by the support of \( \psi(2^m \xi) \), we have
\[
\int_{|\xi| \leq 2^{1-m}} \int \frac{N2^{-m}|x - (ty + (1-t)y_0) - r\theta|}{(1 + 2^{-2m}|x - (ty + (1-t)y_0) - r\theta|^2)^{N+1}} d\xi \leq C.
\]
Integrating with \( r \), we get a bound \( 2^j \). Integrating with \( t \), we get finite bound 1. Note that we suppose that \( \|\Omega\|_\infty \leq 2^n \|\Omega\|_1 \), therefore integrating with \( \theta \), we get a bound \( 2^{-n\gamma(d-1)+n} \|\Omega\|_1 \). Combining these bounds, we can get the required estimate for \( F_{m,3}(\cdot,y) \).

**Lemma 4.5.** For a fixed \( y \in Q \), we have
\[
\|F_{m,2}(\cdot,y)\|_1 \leq C\left(n^{2\delta-1}2^{-n} + 2^{-n\delta}\right)2^{-n\gamma(d-1)+n} \|\Omega\|_1,
\]
where \( C \) is independent of \( y \).
Proof. First, notice that $2^{j-2} \leq r \leq 2^{j+2}$. Write $K^n_j(y + r\theta, y) - K^n_j(y_0 + r\theta, y_0)$ as

$$
\left( K^n_j(y + r\theta, y) - K^n_j(y_0 + r\theta, y_0) \right) + \left( K^n_j(y_0 + r\theta, y) - K^n_j(y_0 + r\theta, y_0) \right).
$$

Since $y \in Q$ and $y_0$ is the center of $Q$, we have $|y - y_0| \leq 2^{j-n}$. Therefore by the mean value formula, Minkowski’s inequality and (2.5), we get

$$
\left| K^n_j(y + r\theta, y) - K^n_j(y_0 + r\theta, y) \right|
= \left| \int_{\mathbb{R}^d} \left( \eta_{j-l_3(n)}(y + r\theta - z) - \eta_{j-l_3(n)}(y_0 + \theta - z) \right) K_j(z, y) dz \right|
= \left| \int_{\mathbb{R}^d} \left( \int_0^1 (y - y_0, \nabla(\eta_{j-l_3(n)})(ty + (1-t)y_0 + r\theta - z)) dt \right) K_j(z, y) dz \right|
\leq |y - y_0| 2^{-j+l_3(n)} \sum_{i=1}^n \| \partial_{x_i} \eta \|_1 \| K_j(\cdot, y) \|_\infty
\lesssim n^{2s-1} 2^{-n-jd}.
$$

We write

$$
\left| K^n_j(y_0 + r\theta, y) - K^n_j(y_0 + r\theta, y_0) \right|
= \left| \int_{\mathbb{R}^d} \eta_{j-l_3(n)}(y_0 + r\theta - z) \left( K_j(z, y) - K_j(z, y_0) \right) dz \right|
\leq \left| \int_{\mathbb{R}^d} \eta_{j-l_3(n)}(y_0 + r\theta - z) \left( \phi_j(z - y) - \phi_j(z - y_0) \right) K(z, y) dz \right|
+ \left| \int_{\mathbb{R}^d} \eta_{j-l_3(n)}(y_0 + r\theta - z) \left( K(z, y) - K(z, y_0) \right) \phi_j(z - y_0) dz \right|
=: P_1 + P_2.
$$

Consider $P_1$ firstly. Using the fact $|y - y_0| \lesssim 2^{j-n}$ and the support of $\phi$, we have $2^{j-2} \leq |z - y| \leq 2^{j+2}$. Applying the mean value formula, we get

$$
P_1 \leq |y - y_0| 2^{-j} \| K(\cdot, y) \|_\infty \| \eta \|_1 \lesssim 2^{-n-jd}.
$$

For the term $P_2$, by $|y - y_0| < 2^{j-n}$ and $2^{j-1} \leq |z - y_0| \leq 2^{j+1}$, we have $2|y - y_0| \leq |z - y_0|$. By the regularity condition (1.9), we have

$$
P_2 \leq C \int \eta_{j-l_3(n)}(y_0 + r\theta - z) \frac{|y - y_0|^{\delta}}{|z - y_0|^{d+\delta}} dz \lesssim 2^{-n\delta-jd}.
$$

Combining the estimates of $P_1$ and $P_2$, we conclude that (4.15) is controlled by $2^{-n\delta-jd}$.

Now we come back to estimate the $L^1(\mathbb{R}^d)$ norm of $F_{m,2}(\cdot, y)$. It is easy to check

$$
|(I - 2^{-2m} \Delta \xi)^N \psi(2^m \xi)| \leq C.
$$

Since we need to get the $L^1$ estimate of $F_{m,2}(\cdot, y)$, by the support of $\psi(2^m \xi)$, we have

$$
\int_{|\xi| \leq 2^{1-m}} \int \left( 1 + 2^{-2m} |x - y - r\theta|^2 \right)^{-N} dx d\xi \leq C.
$$
Integrating with \( r \), we get
\[
\int_{2^{j-2}}^{2^{j+2}} r^{d-1} dr \approx 2^{jd}.
\]
Integrating with \( \theta \), we get a bound \( 2^{-n\gamma(d-1)+n\epsilon} \| \Omega \|_1 \). Combining with the estimates in (4.14) and (4.15), the \( L^1 \) norm of \( F_{m,2}(\cdot, y) \) is bounded by
\[
\left( n^{2\delta-1} 2^{-n} + 2^{-n\delta} \right) 2^{-n\gamma(d-1)+n\epsilon} \| \Omega \|_1,
\]
which is the required bound. \( \square \)

4.4. Proof of Lemma 2.4

Let us come back to the proof of Lemma 2.4, it is sufficient to consider \( I \) and \( II \) in (4.1). By (4.3), (4.4) and (4.13), we have

\[
I + II \leq \frac{2}{\lambda} \sum_{n \geq 100} \sum_{j} \sum_{v} \sum_{l(Q)=2^{j-n}} \left[ C_{\mu,d}^{-1} \int_{Q^2} b_{Q} \right] \left[ \sum_{k < m} \| b_{Q} \|_1 + \| b_{Q} \|_1 \right]
\]

\[
\leq \frac{2}{\lambda} \sum_{n \geq 100} \sum_{j} \sum_{v} \sum_{l(Q)=2^{j-n}} \sup_{y \in Q} \left[ C_{\mu,d}^{-1} \int_{Q^2} b_{Q} \right] \left[ \sum_{k < m} \| b_{Q} \|_1 + \| b_{Q} \|_1 \right]
\]

Notice \( m = j - \lfloor n \epsilon \rfloor \) and \( \text{card}(\Theta_n) \leq 2^{n\gamma(d-1)} \). Now applying Lemma 4.2 with \( N = \lfloor \frac{d}{2} \rfloor + 1 \), then Lemma 4.3, Lemma 4.4, Lemma 4.5 and the fact \( [n \epsilon_0] \leq n \epsilon_0 < [n \epsilon_0] + 1 \) imply

\[
I + II \leq \lambda^{-1} \sum_{n \geq 100} \sum_{j} \sum_{l(Q)=2^{j-n}} \| b_{Q} \|_1 \| \Omega \|_1 \left[ C_{\mu,d}^{-1} \left( 2^{s_1 n} + n^{2\delta-1} 2^{s_2 n} + 2^{s_3 n} + n^{2\delta-1} N_1 2^{s_4 n} \right) \right],
\]

where
\[
s_1 = \mu + \gamma(d-1) + \gamma \left( \frac{d}{2} \right) + 1 + \epsilon_0 + \epsilon,
\]
\[
s_2 = \mu + \gamma(d-1) + \gamma \left( \frac{d}{2} \right) + 1 + \epsilon,
\]
\[
s_3 = \mu + \gamma(d-1) + \gamma \left( \frac{d}{2} \right) + 1 - \delta + \epsilon,
\]
\[
s_4 = -\epsilon_0 N_1 + \gamma N_1 + 2 \left( \frac{d}{2} \right) \gamma + \epsilon.
\]

Now we choose \( 0 < \epsilon \ll \gamma \ll \epsilon_0 \ll 1, 0 < \mu \ll \delta, 0 < \gamma \ll \delta, 0 < \epsilon \ll \delta \) and \( N_1 \) large enough such that

\[
\max\{s_1, s_2, s_3, s_4\} < 0.
\]

Therefore

\[
I + II \leq \frac{\| \Omega \|_1}{\lambda} \| b \|_1 \sum_{n \geq 100} \left[ C_{\mu,d}^{-1} \left( 2^{s_1 n} + n^{2\delta-1} 2^{s_2 n} + 2^{s_3 n} + n^{2\delta-1} N_1 2^{s_4 n} \right) \right] \approx \frac{\| \Omega \|_1}{\lambda} \| f \|_1.
\]

Hence we finish the proof of Lemma 2.4, thus we prove Theorem 1.1. \( \square \)
5. Applications of the criterion

In this section, we will give some important and interesting applications of Theorem 1.1. Notice the following well known embedding relations between some function spaces on $S^{d-1}$:

$$L^\infty(S^{d-1}) \subseteq L^r(S^{d-1}) \ (1 < r < \infty) \subseteq L^{\log^+ L}(S^{d-1}) \subseteq L^1(S^{d-1}),$$

and $\|\Omega\|_{L^{\log^+ L}} \lesssim \|\Omega\|_r$ when $\Omega \in L^r(S^{d-1}) \ (1 < r \leq \infty)$. Thus, we may get the following corollary of Theorem 1.1:

**Corollary 5.1.** Suppose $K$ satisfies (1.8) and (1.9). Let $\Omega$ satisfy (1.1) and $\Omega \in L^r(S^{d-1})$ for $1 < r \leq \infty$. In addition, suppose $\Omega$ and $K$ satisfy some appropriate cancellation conditions such that $T_\Omega f(x)$ in (1.7) is well defined for $f \in C_c^\infty(\mathbb{R}^d)$ and maps $L^2(\mathbb{R}^d)$ to itself with bound $\|\Omega\|_r$. Then for any $\lambda > 0$, we have

$$\lambda m(\{x \in \mathbb{R}^d : |T_\Omega f(x)| > \lambda\}) \lesssim C_{\Omega, r} \|f\|_1$$

where $C_{\Omega, r} = \|\Omega\|_r + \int_{S^{d-1}} |\Omega(\theta)| \left(1 + \log^+(|\Omega(\theta)|/\|\Omega\|_1)\right)d\theta$.

Obviously, the weak type (1,1) bounds of rough singular integral $T$ given in Theorem B are immediate consequences of applying Theorem 1.1. In fact, it is easy to see that $K(x, y) = \frac{1}{|x - y|^d}$ in the kernel of the singular integral $T$ defined in (1.4) satisfies (1.8) and (1.9) with $\delta = 1$.

In the following we give some applications of Theorem 1.1 and Corollary 5.1 involving Calderón commutator and its generalizations, which arise naturally in the studies of the Cauchy integral on Lipschitz curve and differential equations with non-smooth coefficients, see [4], [18], [27] and [28] for the background and applications of Calderón commutator.

5.1. Calderón commutator.

Recall Caldeón commutator defined in (1.5),

$$T_{\Omega, A} f(x) = \text{p.v.} \int_{\mathbb{R}^d} \frac{\Omega(x - y)}{|x - y|^d} \cdot \frac{A(x) - A(y)}{|x - y|} \cdot f(y) dy,$$

As a first application of Theorem 1.1 we get the weak type (1,1) boundedness of Calderón commutator $T_{\Omega, A}$.

**Theorem 5.2.** Suppose $\Omega \in L^{\log^+ L}(S^{d-1})$ satisfying (1.1) and (1.6) and $A \in \text{Lip}(\mathbb{R}^d)$. Then for any $\lambda > 0$, we have

$$m(\{x \in \mathbb{R}^d : |T_{\Omega, A} f(x)| > \lambda\}) \lesssim \lambda^{-1} C_{\Omega} \|\nabla A\|_\infty \|f\|_1.$$

**Proof.** Under the conditions in Theorem 5.2, by Theorem C, we know that $T_\Omega$ is bounded on $L^2(\mathbb{R}^d)$ with bound $\|\nabla A\|_\infty \|\Omega\|_{L^{\log^+ L}}$. Hence, to prove the Theorem 5.2 by Theorem 1.1 it is enough to show that the kernel

$$K(x, y) = \frac{1}{|x - y|^d} \frac{A(x) - A(y)}{|x - y|}$$
satisfies (1.8) and (1.9). Since \( A \in \text{Lip}(\mathbb{R}^d) \), it is trivial to see that (1.8) holds. Suppose \(|x_1 - y| > 2|x_1 - x_2|\), then we have \(|x_1 - y| \approx |x_2 - y|\). Applying the mean value formula, we have

\[
|K(x_1, y) - K(x_2, y)| \leq \left| \frac{1}{|x_1 - y|^{d+1}} - \frac{1}{|x_2 - y|^{d+1}} \right| |A(x_1) - A(y)| + \frac{|A(x_1) - A(x_2)|}{|x_2 - y|^{d+1}}
\]

\[
\lesssim \|\nabla A\|_{\infty} \frac{|x_1 - x_2|}{|x_1 - y|^{d+1}}.
\]

Thus the first inequality in (1.9) is valid. The proof of the second inequality in (1.9) is similar. Hence we complete the proof.

\[\square\]

5.2. Higher order Calderón commutator.

In 1990, S. Hofmann \cite{23} gave the \( L^p (1 < p < \infty) \) boundedness of the higher order Calderón commutator defined by

\[
T^k_{\Omega,A}f(x) = \text{p.v.} \int_{\mathbb{R}^d} \frac{\Omega(x-y)}{|x-y|^d} \cdot \left( \frac{A(x) - A(y)}{|x-y|} \right)^k \cdot f(y) dy,
\]

where \( \Omega \) satisfies (1.1), \( A \in \text{Lip}(\mathbb{R}^d) \) and \( k \geq 1 \).

**Theorem D** (\cite{23}). Suppose that \( \Omega \in L^\infty(S^{d-1}) \) and satisfies the moment conditions

\[
\int_{S^{d-1}} \Omega(\theta) \theta^\alpha d\theta = 0, \quad \text{for all } \alpha \in \mathbb{Z}^d_+ \text{ with } |\alpha| = k.
\]

Then the higher order Calderón commutator \( T^k_{\Omega,A} \) defined in (5.1) is a bounded operator on \( L^p(\mathbb{R}^d) \) for \( 1 < p < \infty \) with bound \( \|\Omega\|_{\infty} \|\nabla A\|_{\infty}^k \).

Applying Corollary 5.1 we show that the higher order Calderón commutator \( T^k_{\Omega,A} \) is of weak type (1,1).

**Theorem 5.3.** Suppose that \( k \geq 1, \Omega \in L^\infty(S^{d-1}) \) satisfying (1.1) and (5.2) and \( A \in \text{Lip}(\mathbb{R}^d) \). Then for any \( \lambda > 0 \), we have

\[
m(\{x \in \mathbb{R}^d : |T^k_{\Omega,A}f(x)| > \lambda\}) \lesssim \lambda^{-1} \|\Omega\|_{\infty} \|\nabla A\|_{\infty}^k \|f\|_1.
\]

**Proof.** The proof is similar to the proof of Theorem 5.2. By Corollary 5.1 and Theorem D, it only needs to check that the kernel

\[
K(x,y) = \frac{1}{|x-y|^d} \left( \frac{A(x) - A(y)}{|x-y|} \right)^k
\]

satisfies (1.8) and (1.9). On one hand, the verification of (1.8) is trivial since \( A \in \text{Lip}(\mathbb{R}^d) \). On the other hand, if \(|x_1 - y| > 2|x_1 - x_2|\), we have \(|x_1 - y| \approx |x_2 - y|\). Applying the mean value
formula, we get
\[ |K(x_1, y) - K(x_2, y)| \]
\[ \leq \left| \frac{1}{|x_1 - y|^d} - \frac{1}{|x_2 - y|^d} \right| \left| \frac{A(x_1) - A(y)}{|x_1 - y|} \right|^k \]
\[ + \frac{1}{|x_2 - y|^d} \left| \frac{A(x_1) - A(y)}{|x_1 - y|} \right|^k - \left( \frac{A(x_2) - A(y)}{|x_2 - y|} \right)^k \]
\[ \lesssim \|\nabla A\|_{\infty}^k \left| \frac{x_1 - x_2}{x_1 - y}|^{d+1}. \right. \]

Thus the first inequality in (1.9) is valid. The proof of the second inequality in (1.9) is similar. Hence we complete the proof. \[ \square \]

5.3. General Calderón commutator.

In [3], Calderón introduce the following more general commutator

(5.3)
\[ T_{\Omega,F,A}f(x) = \text{p.v.} \int_{\mathbb{R}^d} \frac{\Omega(x - y)}{|x - y|^d} F\left( \frac{A(x) - A(y)}{|x - y|} \right) f(y) dy. \]

It is well known that the study of this commutator is closely connected to the Cauchy integral on Lipschitz curves and the elliptic boundary value problem on non-smooth domain (see [4], [3], [5] and [16]). In [5], by using the method of rotation, A. P. Calderón et al. pointed that

**Theorem E** ([5]). Suppose \( \Omega, F \) and \( A \) satisfy the following conditions, then the commutator \( T_{\Omega,F,A} \) defined in (5.3) is bounded on \( L^p(\mathbb{R}^d) \) for \( 1 < p < \infty \):

(i) \( \Omega(-\theta) = -\Omega(\theta) \) for \( \theta \in \mathbb{S}^{d-1} \) and \( \Omega \in L^1(\mathbb{S}^{d-1}) \);

(ii) \( A \in \text{Lip}(\mathbb{R}^d) \);

(iii) \( F(t) = F(-t) \) for \( t \in \mathbb{R} \) and \( F(t) \) is real analytic in \( \{|t| \leq \|\nabla A\|_{\infty}\} \).

Using Theorem 1.1, we may get a weak type \((1,1)\) boundedness of \( T_{\Omega,F,A} \).

**Theorem 5.4.** Suppose \( \Omega, A \) and \( F \) satisfy the conditions (i)~(iii) in Theorem E. If \( \Omega \in L \log^+ L(\mathbb{S}^{d-1}) \), then the general Calderón commutator \( T_{\Omega,F,A} \) is of weak type \((1,1)\). That is, for any \( \lambda > 0 \) and \( f \in L^1 \),

\[ m(\{x \in \mathbb{R}^d : |T_{\Omega,F,A}f(x)| > \lambda\}) \lesssim \lambda^{-1} C_\Omega \|f\|_1. \]

**Proof.** By Theorem 1.1 and Theorem E, it is enough to show that the kernel

\[ K(x,y) = \frac{1}{|x - y|^d} F\left( \frac{A(x) - A(y)}{|x - y|} \right) \]

satisfies (1.8) and (1.9). It is easy to check that

\[ |K(x,y)| \leq \frac{1}{|x - y|^d} \|F\|_{L^\infty(B(0,\|\nabla A\|_{\infty}))}. \]
Suppose $|x_1 - y| > 2|x_1 - x_2|$, then $|x_1 - y| \approx |x_2 - y|$. Using the mean value formula and the fact $F$ is analytic in $\{|t| \leq \|\nabla A\|_{\infty}\}$, we have

$$|K(x_1, y) - K(x_2, y)| \leq \frac{1}{|x_1 - y|^d} + \frac{1}{|x_2 - y|^d} \left| F\left(\frac{A(x_1) - A(y)}{|x_1 - y|}\right) \right|$$

$$+ \frac{1}{|x_2 - y|^d} \left| F\left(\frac{A(x_2) - A(y)}{|x_2 - y|}\right) - F\left(\frac{A(x_1) - A(y)}{|x_1 - y|}\right) \right|$$

$$\lesssim \frac{|x_1 - x_2|}{|x_1 - y|^{d+1}} \left( \|F\|_{L^\infty(B(0,\|\nabla A\|_{\infty}))} + \|\nabla A\|_{\infty} \|\nabla F\|_{L^\infty(B(0,\|\nabla A\|_{\infty}))} \right).$$

Thus the first inequality in (1.9) is valid. Similarly we can establish the second inequality in (1.9). Therefore we complete the proof. □

5.4. Calderón commutator of Bajsanski-Coifman type.

In 1967, Bajsanski and Coifman [1] introduced another kind of general Calderón commutator as follows. For a multi-indices $\alpha \in \mathbb{Z}_+^d$, set $A_{\alpha}(x) = \partial_x^\alpha A(x)$ and

$$P_l(A, x, y) = A(x) - \sum_{|\alpha| < l} \frac{A_{\alpha}(y)}{\alpha!}(x - y)^\alpha,$$

where $l \in \mathbb{N}$. Define the singular operator $T_{\Omega,A,l}$ as

$$T_{\Omega,A,l}f(x) = p.v. \int_{\mathbb{R}^d} \frac{\Omega(x - y)}{|x - y|^d} \cdot \frac{P_l(A, x, y)}{|x - y|^l} \cdot f(y)dy,$$

where $\Omega$ satisfies (1.1) and (1.3). Clearly, when $l = 1$, the operator $T_{\Omega,A,1}$ is just Calderón commutator $T_{\Omega,A}$ defined in (5.3).

**Theorem F** ([1]). The commutator $T_{\Omega,A,l}$ defined in (5.4) is bounded on $L^p(\mathbb{R}^d)$ for $1 < p < \infty$ if $l \in \mathbb{N}$ and $\Omega, A$ satisfy the following conditions:

(i) $\Omega \in L \log^+ L(S^{d-1})$ and satisfies (1.1) and

$$\int_{S^{d-1}} \Omega(\theta)\theta^{\alpha}d\theta = 0, \quad \text{for all } \alpha \in \mathbb{Z}_+^d \text{ with } |\alpha| = l;$$

(ii) $A_{\alpha} \in L^\infty(\mathbb{R}^d)$ for $|\alpha| = l.$

E. M. Stein pointed out that the operator $T_{\Omega,A,l}$ is of weak type $(1, 1)$ if $\Omega \in Lip(S^{d-1}).$

**Theorem G** (E. M. Stein, see [1] p. 16)). Suppose $l \in \mathbb{N}$ and $\Omega, A$ satisfy the same conditions as Theorem F, but replacing $\Omega \in L \log^+ L(S^{d-1})$ by $\Omega \in Lip(S^{d-1})$, then $T_{\Omega,A,l}$ is of weak type $(1, 1)$.

Applying Theorem 1.1 we may improve Theorem G essentially.

**Theorem 5.5.** Let $l \geq 1$. Suppose $\Omega \in L \log^+ L(S^{d-1})$ satisfying (1.1) and (5.5). Let $A_{\alpha} \in L^\infty(\mathbb{R}^d)$ for every $|\alpha| = l$. Then for any $\lambda > 0$, we have

$$m(\{x \in \mathbb{R}^d : |T_{\Omega,A,l}f(x)| > \lambda\}) \lesssim \lambda^{-1}C_{\Omega} \sum_{|\alpha| = l} \|A_{\alpha}\|_{\infty} \|f\|_1.$$
Remark 5.6. When \( l = 1 \), \( T_{\Omega,A,1} \) equals to \( T_{\Omega,A} \) defined in (1.5). Thus, Theorem 5.2 is just the special case of Theorem 5.5 when \( l = 1 \).

Proof. By Theorem 1.1 and Theorem F, to prove Theorem 5.5, it suffices to show that the kernel

\[
K(x,y) = \frac{1}{|x-y|^d} \frac{P_l(A,x,y)}{|x-y|^l}
\]

satisfies (1.8) and (1.9). By the fact \( A_\alpha \in L^\infty(\mathbb{R}^d) \) for every \( |\alpha| = l \) and the following Taylor expansion

\[
P_l(A,x,y) = \sum_{|\alpha|=l} \frac{(x-y)^\alpha}{\alpha!} \int_0^1 (1-s)^{l-1} A_\alpha(y+s(x-y)) ds,
\]

we conclude that

\[
|K(x,y)| \lesssim \sum_{|\alpha|=l} \|A_\alpha\|_\infty \frac{1}{|x-y|^d}.
\]

Choose \( |x_1-y| > 2|x_1-x_2| \). Then we have \( |x_1-y| \approx |x_2-y| \). By using the Taylor expansion, we can write

\[
P_l(A,x,y) = p.v. \int_{\mathbb{R}^d} \frac{\Omega(x,y)}{|x-y|^{d+\gamma}} d \mu,
\]

where \( \gamma = \sqrt{-1} \).

The proof of the second inequality in (1.9) is similar. Hence (1.9) holds for \( K(x,y) \). Thus we finish the proof. \( \square \)

5.5. General singular integral of Muckenhoupt type.

In 1960, B. Muckenhoupt [26] considered a modification of singular integral and generalized Calderón and Zygmund’s work [6] and [7] on the fractional integration in the following. Suppose that \( \Omega \) satisfies (1.2) \( \sim \) (1.3). Then the following singular integral operator is well defined for \( f \in C^\infty_c(\mathbb{R}^d) \) and \( r \in \mathbb{R} \setminus \{0\} \),

\[
T_{\Omega,ir} f(x) = p.v. \int_{\mathbb{R}^d} \frac{\Omega(x,y)}{|x-y|^{d+\gamma}} f(y) dy,
\]

where \( i = \sqrt{-1} \).

Theorem H ([26, Theorem 8]). With the above definition of the general singular integral operator \( T_{\Omega,ir} \) and \( T_{\Omega,ir} \) is bounded on \( L^p(\mathbb{R}^d) \) with bound \( C_l \|\Omega\|_1 \) for \( 1 < p < \infty \). Here we should point out \( \Omega \) satisfies additional cancelation condition (1.2) so that \( T_{\Omega,ir} f \) is well defined for \( f \in C^\infty_c(\mathbb{R}^d) \).

As a final application of Theorem 1.1 we can establish the weak type (1,1) boundedness of \( T_{\Omega,ir} \).
Theorem 5.7. Suppose $\Omega$ satisfies (1.1), (1.2) and $\Omega \in L \log^+ L(S^{d-1})$. Then for any $\lambda > 0$,
$$m(\{x \in \mathbb{R}^d : |T_{\Omega,ir}f(x)| > \lambda\}) \lesssim \lambda^{-1}C_{\Omega}\|f\|_1.$$ 

Proof. By Theorem 1.3 and Theorem II, it suffices to verify the kernel
$$K(x, y) = \frac{1}{|x - y|^{d+ir}}$$
satisfying (1.8) and (1.9). It is easily to see that $|K(x, y)| = \frac{1}{|x - y|^{d+ir}}$. Suppose $|x_1 - y| > 2|x_1 - x_2|$, then $|x_1 - y| \approx |x_2 - y|$. By using the mean value formula, we have
$$|K(x_1, y) - K(x_2, y)|$$
$$\leq \left|\frac{1}{|x_1 - y|^{d+ir}} - \frac{1}{|x_2 - y|^{d+ir}}\right| + \frac{1}{|x_2 - y|^{d+ir}}\left|e^{-ir \ln |x_1 - y|} - e^{-ir \ln |x_2 - y|}\right|$$
$$\lesssim \frac{|x_1 - x_2|}{|x_1 - y|^{d+1}}.$$ 

So the first inequality in (1.9) is valid. Similarly we can establish the second inequality in (1.9). Hence we complete the proof. 

6. Some further problems

In the previous section, we give lots of applications of Theorem 1.3. However, there are still many operators that do not fall into the scope of our main result’s applications. Below we list some open problems related to weak type (1,1) bound (For more we refer the reader to see [30, 21]).

6.1. Oscillatory singular integral operator with rough kernel. Let $P(x, y)$ be a real-valued polynomial on $\mathbb{R}^d \times \mathbb{R}^d$. S. Lu and Y. Zhang [25] showed that the operator defined by
$$Tf(x) = \text{p.v.} \int_{\mathbb{R}^d} e^{iP(x,y)}\Omega(x-y)\frac{\Omega(x-y)}{|x-y|^d}f(y)dy$$
is bounded on $L^p(\mathbb{R}^d)(1 < p < +\infty)$ if $\Omega$ satisfies (1.1), (1.2) and $\Omega \in L^r(S^{d-1})(1 < r \leq +\infty)$. S. Challino and M. Christ [9] proved that this operator is of weak type (1,1) if $\Omega \in Lip(S^{d-1})$. It is interesting to show $T$ is weak (1,1) bounded if $\Omega$ is rough.

6.2. Commutator of Christ-Journé type. Let $a \in L^\infty(\mathbb{R}^d)$, let $K$ be the Calderón-Zygmund convolution kernel. M. Christ and J. L. Journé [11] proved the operator defined by
$$T_{a,k}f(x) = \text{p.v.} \int_{\mathbb{R}^d} K(x-y)(m_{x,y}a)^k f(y)dy$$
maps $L^p(\mathbb{R}^d)$ to itself for $1 < p < +\infty$, where $m_{x,y}a = \int_0^1 a(sx + (1-s)y)ds$. A. Seeger [30] showed that $T_{a,1}$ is of weak type (1,1). It is open whether $T_{a,k}$ is weak (1,1) bounded for $k \geq 2$. If replacing the Calderón-Zygmund convolution kernel $K(x)$ by $\Omega(x)/|x|^d$ with $\Omega$ is homogeneous of degree zero, S. Hofmann [24] proved this kind of operator maps $L^p(w)$ to itself for $w$ an $A_p$ weight and $1 < p < \infty$ if $\Omega \in L^\infty(S^{d-1})$. One can also ask a question whether it is weak type (1,1) bounded if $\Omega \in L^\infty(S^{d-1})$. 

WEAK TYPE (1,1) BOUND CRITERION 25
6.3. Maximal singular integral operator with rough kernel. Suppose $K$ satisfies (1.8) and (1.9). Let $\Omega$ satisfy (1.1) and $\Omega \in L^{\log^+} L(S^{d-1})$. Suppose $\Omega$ and $K$ satisfy some appropriate cancellation conditions such that the following operator

$$T_* f(x) = \sup_{\varepsilon > 0} \left| \int_{|x-y| > \varepsilon} \Omega(x-y) K(x,y) f(y) dy \right|.$$ 

is well defined for $f \in C^\infty_0(\mathbb{R}^d)$ and extends to a bounded operator on $L^2(\mathbb{R}^d)$ with bound $C \|\Omega\|_{L^{\log^+} L}$. Then a natural question is whether $T_*$ is of weak type (1,1). When $K(x,y) = 1/|x-y|^d$, Calderón and Zygmund [7] showed that $T_*$ is $L^p(\mathbb{R}^d)$ bounded for $1 < p < +\infty$ if $\Omega \in L^{\log^+} L(S^{d-1})$. But it is unknown whether $T_*$ is of weak type (1,1) even when $\Omega \in L^\infty(S^{d-1})$. And when $K(x,y) = A(x) - A(y) / |x-y|^{d+1}$, $A$ is a Lipschitz function, A. P. Calderón [2] proved that $T_*$ is $L^p(\mathbb{R}^d)$ bounded for $1 < p < +\infty$ if $\Omega \in L^{\log^+} L(S^{d-1})$. Also the weak type (1,1) bound is unknown in this case.

**Acknowledgements.** Xudong Lai would like to thank Andreas Seeger for some helpful discussions related to this work. The authors thank the referee for his/her important comments and very valuable suggestions which improve this manuscript greatly.
