Supporting Information

ABSTRACT: We report herein an easy, mild, and robust Pd-catalyzed enantioselective hydroalkynylation reaction of achiral cyclopropenes. Commercially available Pd(acac)₂ and (R)-DM-BINAP proved to be the best combination to reach high diastereo- and enantioselectivities.

KEYWORDS: enantioselective, hydroalkynylation, cyclopropenes, cyclopropanes, palladium

The diastereo- and enantioselective addition of organometallic species across unactivated 1,2-disubstituted double bonds (carbometalation) still stands nowadays as one of the most challenging transformations in organic synthesis.¹ Because of the release of ring strain, the addition on cyclopropenes represents a particular but successful case providing a new entry to a large variety of polysubstituted enantioenriched cyclopropanes.² In this context, and since the pioneering work of Lautens,³ Fox,⁴ and Nakamura,⁵ the direct functionalization of achiral, unsaturated, three-membered carbocycles have attracted much attention.⁶ We and others have reported the catalytic enantioselective copper-, rhodium-, and lanthanide-catalyzed addition of sp³-hybridized alkyl groups⁸−¹⁰ as well as the addition of heteroelements¹⁰a,¹¹ with excellent diastereo- and enantioselectivities (Scheme 1a).

Scheme 1. Direct Functionalization of Achiral Unsatuated Cyclopropanes

However, an important but still missing transformation in this arsenal of direct functionalization of achiral unsaturated three-membered carbocycles was the introduction of alkynyl groups,¹² until the very recent report of Hou describing the highly diastereo- and enantioselective half-sandwich gadolinium-catalyzed enantioselective hydroalkynylation of cyclopropenes (Scheme 1b).¹³ Because diastereo- and enantiomerically pure alkynyl cyclopropanes are motifs present in several natural products¹⁴ and are considered as important building blocks in the construction of more complex skeletons,¹⁵ we wanted to develop an alternative more efficient and easier approach to reach these scaffolds with high selectivities. The availability of palladium complexes combined with their user-friendliness.

Cyclopropene 1a and commercially available phenylacetylene were used as model substrates to explore the diastereo- and enantioselective Pd-catalyzed hydroalkynylation reaction. Various parameters such as the nature of the: (i) catalyst, (ii) chiral ligand, and (iii) solvent were screened, as shown in Table 1. (See the Supporting Information for full details.) Our preliminary experiment was performed with Pd(OAc)₂ as the catalyst and (S)-DTBM-SEGPHOS as the ligand, for 16 h. Under this experimental condition, we were pleased to observe that alkynylated cyclopropane 2a was formed with a moderate enantiomeric ratio (Table 1, entry 1, er 64:36).

On the basis of this initial finding, different chiral ligands were evaluated (Table 1, entries 2–6), and the commercially available (R)-DM-BINAP was found to be the best ligand (Table 1, entry 6, er 86:14). Using (R)-DM-BINAP as the most effective ligand, different solvents were tested (Table 1, entries 7–11), and DCM, THF, and Et₂O provided similar selectivities. Further additional screening of palladium salts and
solvents (Table 1, entries 12−20) revealed that the ideal combination was Pd(acac)₂ with (R)-DM-BINAP in Et₂O (Table 1, entry 16). The desired alkynylcyclopropane 2a was obtained with excellent enantio- and diastereoselectivity (er 98:02, dr 20:1). Having established the best experimental conditions for a mild Pd-catalyzed diastereo- and enantioselective hydroalkynylation reaction of achiral cyclopropenes 1a, we then explored the nature of the substituents of the three-membered rings on the selectivity of the reaction.

Scheme 2. Pd-Catalyzed Enantioselective Hydroalkynylation Reaction of Cyclopropenes with Different Terminal Alkynes

"Determined by chiral HPLC. ¹No detection of the desired product 2a; cyclopropene 1a was recovered. ²Reactions were run on a 0.05 mmol scale using 2 equiv of the alkyne, Pd salt (5 mol %), and L* (7.5 mol %) in the corresponding solvent (0.1 M), and the reaction mixture was stirred at room temperature for 16 h. In all cases, conversion was >70%.

Scheme 3. Pd-Catalyzed Enantioselective Hydroalkynylation Reaction of Cyclopropenes with Different Terminal Alkynes

Encouraged by this result, the simplest dimethyl cyclopropene was prepared and submitted to our catalytic Pd-catalyzed enantioselective alkynylation reaction. We were pleased to find that the desired alkynylated cyclopropane 2g could be isolated in moderate yield with a promising...
enantiomeric ratio of 88:12. In the last two cases, a substitution on C1 of the cyclopropenyl ring would lead to the creation of two quaternary stereocenters. Unfortunately, in this case, our catalytic procedure does not work anymore. Stimulated by these positive results, we then turned our attention to the nature of the nucleophilic alkynyl groups that could be introduced. A series of different substituted aromatic acetylenes were added to cyclopropane 1a, and in all cases, excellent selectivities were observed. Alkyl substituents could be in either a meta or para position of the aromatic ring without drastically altering the diastereo- and enantioselectivity (Scheme 3, compare 2h with 2i and 2j). Electron-donating groups provided the expected alkynylated cyclopropanes (2k and 2l) with identical enantiomeric ratios. It is worth mentioning that electron-deficient para-bromo-phenyl acrylene could also be tolerated in this transformation and afford the desired cyclopropane 2m in 79% yield with excellent diastereo- and enantioselective control (dr 20:1, er up to 96:04). Interestingly, ortho-, meta-, and para-fluoro-phenyl acrylene gave the desired fluoro-containing enantiomerically enriched alkynyl cyclopropanes (Scheme 3, 2n–p) also with excellent stereocontrol. To establish the absolute configuration of the alkynyl cyclopropanes, product 2r has been prepared, and the configuration was determined by X-ray diffraction analysis.\textsuperscript{17} All other absolute configurations of products have been assigned by analogy.\textsuperscript{18}

Various functional groups present on the alkynyl part can also be tolerated, such as ester, ferrocene, pyridine, and acetal (Scheme 3, 2s–v). An important extension of this approach is the catalytic enantioselective addition of 1,3-butadiyn-1-ylibenzene. In the two examined cases (Scheme 3, 2w and 2x), the diynyl cyclopropanes were obtained with excellent diastereo- and enantioselectivities. It should be noted that TMS-substituted alkynes led to nearly racemic products with (R)-DM-BINAP, whereas alkyl-substituted alkynes did not lead to the expected products.

Encouraged by the excellent selectivity of the last two examples in Scheme 3, we were then wondering if this approach could be extended to more challenging systems, and we were particularly interested in the catalytic enantioselective addition of conjugated enynes. Thus a series of enynes were synthesized and tested under our standard conditions (Scheme 4). To our delight, cyclopropanes 3a–k were isolated in moderate yield but with excellent diastereo- and enantioselectivity (dr 20:1, er up to 99:01). For instance, the Pd-catalyzed enantioselective addition of (E)-4-phenyl-3-buten-1-yne to 1a provided the product 3a in 57% yield with a 94:06 enantiomeric ratio. A variously substituted aromatic ring can be used without altering the diastereo- and enantioselectivities.

In conclusion, we have developed a friendly and easy to use Pd-catalyzed enantioselective hydroalkynylation reaction of achiral cyclopropanes by the addition of different terminal alkynes, diynes, and enynes with Pd(acac), and commercially available (R)-DM-BINAP as a chiral ligand with excellent diastereo- and enantioselectivity. This hydroalkynylation reaction provides a simple, mild, and atom-economical approach toward a large variety of enantiomerically enriched alkynylated cyclopropanes.
