OmpA, a Common Virulence Factor, Is Under RNA Thermometer Control in Yersinia pseudotuberculosis

Daniel Scheller*, Christian Twittenhoff†, Franziska Becker, Marcel Holler and Franz Narberhaus*

Department of Microbial Biology, Ruhr University Bochum, Bochum, Germany

The outer membrane protein OmpA is a virulence factor in many mammalian pathogens. In previous global RNA structure probing studies, we found evidence for a temperature-modulated RNA structure in the 5'-untranslated region (5'-UTR) of the Yersinia pseudotuberculosis ompA transcript suggesting that opening of the structure at host-body temperature might relieve translational repression. Here, we support this hypothesis by quantitative reverse transcription PCR, translational reporter gene fusions, enzymatic RNA structure probing, and toeprinting assays. While ompA transcript levels decreased at 37°C compared to 25°C, translation of the transcript increased with increasing temperature. Biochemical experiments show that this is due to melting of the RNA structure, which permits ribosome binding to the 5'-UTR. A point mutation that locks the RNA structure in a closed conformation prevents translation by impairing ribosome access. Our findings add another common virulence factor to the growing list of pathogen-associated genes that are under RNA thermometer control.

Keywords: gene expression, thermosensor, RNA structure, pathogen, virulence, outer membrane protein, porin

INTRODUCTION

OmpA is a highly abundant and conserved outer membrane protein in Gram-negative bacteria (Smith et al., 2007). It has a barrel-like structure that confers porin activity. Apart from its function in the influx and efflux of various compounds, OmpA is a multifaceted protein with various other functions, hence its designation as a molecular Swiss army knife. For instance, it plays an important role in envelope stability. In Acinetobacter baumannii, it was shown that two highly conserved residues anchor OmpA to the peptidoglycan layer (Park et al., 2012). In addition, OmpA forms complexes with the outer membrane protein Pal, which also associates with the peptidoglycan layer via a conserved α-helical interaction motif (Clavel et al., 1998).

OmpA and OmpA-like proteins have been recognized as virulence factors and are considered as potential vaccine candidates (Confer and Ayalew, 2013). The mode of action by which OmpA contributes to virulence ranges from adherence to epithelial cells and invasion (Smith et al., 2007; Gaddy et al., 2009) to biofilm formation (Weiser and Gotschlich, 1991; Azghani et al., 2002). In Escherichia coli, OmpA contributes to the resistance against serum killing by binding to the C4b-binding protein, which inhibits excessive activation of the complement system (Weiser and Gotschlich, 1991; Prasadara et al., 2002). A. baumannii OmpA confers serum resistance through the acquisition of factor H to the cell surface (Kim et al., 2009).
In addition, secreted *A. baumannii* OmpA is able to facilitate apoptosis by inducing mitochondrial damage and the release of proapoptotic molecules, leading to epithelial cell death (Choi et al., 2005). In a mouse model, *A. baumannii* OmpA is important to induce death as demonstrated by a killing defect of an *ompA* deletion strain (Sánchez-Encinales et al., 2017). In *E. coli* K1, OmpA is required to cause neonatal meningitis by enabling invasion of brain microvascular endothelial cells and crossing the blood-brain barrier (Prasadaraao et al., 1996). OmpA in *Yersinia pestis* and *Yersinia pseudotuberculosis* is important for intracellular survival within macrophages as shown by reduced survival of strains lacking *ompA* (Bartra et al., 2012).

The amount of OmpA and other porins in the outer membrane is tightly regulated in response to numerous external conditions. Like many other genes coding for outer membrane proteins, *E. coli* *ompA* is subject to posttranscriptional regulation by small RNAs (sRNAs; Guillier et al., 2006). The paradigm of this type of control is the regulation of the *ompF* mRNA by the MicF sRNA (Mizuno et al., 1984). The 5'-untranslated region (5'-UTR) of *ompA* base-pairs with the sRNA MicA, which destabilizes the *ompA* transcript and requires the help of the RNA chaperone Hfq (Rasmussen et al., 2005; Udekwu et al., 2005). A second Hfq-dependent sRNA involved in *ompA* regulation in *E. coli* is RseX, which also regulates the expression of another outer membrane protein gene called *ompC* (Douchin et al., 2006).

A fundamentally different mode of riboregulation was recently reported for the *Shigella dysenteriae* *ompA* gene, which is regulated by a fourU-type RNA thermometer (RNAT; Murphy et al., 2020). *Shigella dysenteriae* is a serious foodborne pathogen causing the diarrheal disease shigellosis, and the OmpA protein is involved in intracellular spreading of the pathogen (Ambrosi et al., 2012). The last 20 residues of the 133-nucleotides long 5'-UTR of the *ompA* transcript fold into a simple hairpin structure, in which four uridines pair with GGAG, a part of the Shine-Dalgarno (SD) sequence. This structure is sufficiently strong to inhibit ribosome access at environmental temperatures but labile enough to denature at a host-body temperature in order to facilitate efficient translation resulting in an elevated level of the virulence factor (Mitchell et al., 2020).

Regulating the production of virulence factors like OmpA in response to temperature is a sensible strategy since a shift to 37°C is among the most consistent changes upon arrival in the warm-blooded host. Therefore, many pathogens have established various mechanisms to measure the ambient temperature at the DNA, RNA, or protein level (Steimann and Dersch, 2013; Mandin and Johansson, 2020). A widely used strategy in numerous pathogenic bacteria is the translational control of virulence-associated genes by RNATs (Loh et al., 2018). The sequence and structure of these regulatory elements are surprisingly diverse. Even orthologous genes in related organisms are controlled by unrelated RNATs, and this is also the case for the *ompA* gene. While the *Shigella ompA* transcript is regulated by a fourU thermometer (Murphy et al., 2020), the RNAT upstream of *ompA* in *Y. pseudotuberculosis* presented here is structurally disparate but functionally equivalent.

Like *Shigella*, *Y. pseudotuberculosis* is a notorious foodborne pathogen causing gut-associated diseases. A considerable number of *Yersinia* virulence genes are temperature regulated, often by riboregulatory processes (Knickel et al., 2018). We identified a very promising RNAT upstream of *ompA* by a global RNA structuromics approach, in which *Y. pseudotuberculosis* RNA structures were probed at three different temperatures (Righetti et al., 2016). Here, we set out to study the structure-function relationship of this temperature-labile element and show that it is a functional RNAT allowing induction of OmpA levels at increasing temperature.

## MATERIALS AND METHODS

### Bacterial Strains and Plasmids

Bacterial strains used in this study are listed in Table 1. Cells were grown in lysogeny broth (LB; 1% NaCl, 1% tryptone, and 0.5% yeast extract) at indicated temperatures. Cultures were supplemented with 150 µg/ml ampicillin when necessary. For the induction of the *P*~BAD~ promoter, the medium was supplemented with L-arabinose to a final concentration of 0.01% (*E. coli*) or 0.1% (*Y. pseudotuberculosis*), respectively.

### Plasmid Construction

All utilized oligonucleotides and plasmids are summarized in Tables 2 and 3, respectively. Point mutations were generated by site-directed mutagenesis according to the instruction manual of the QuickChange® mutagenesis kit (Agilent Technologies).

The *ompA* RNAT-*bgaB* fusion plasmid (pBO4435) was constructed by first amplifying the YPK_2630 (*ompA*) 5'-UTR including 30 bp of the *ompA* coding region (108 bp) with primer pairs *ompA* UTR fw/*ompA* UTR rev, digested with NheI and EcoRI and ligated into pBAD2. Insertion of the Shine-Dalgarno (SD) sequence. This structure is sufficiently strong to inhibit ribosome access at environmental temperatures but labile enough to denature at a host-body temperature in order to facilitate efficient translation resulting in an elevated level of the virulence factor (Murphy et al., 2020).

Regulating the production of virulence factors like OmpA in response to temperature is a sensible strategy since a shift to 37°C is among the most consistent changes upon arrival in the warm-blooded host. Therefore, many pathogens have established various mechanisms to measure the ambient temperature at the DNA, RNA, or protein level (Steimann and Dersch, 2013; Mandin and Johansson, 2020). A widely used strategy in numerous pathogenic bacteria is the translational control of virulence-associated genes by RNATs (Loh et al., 2018). The sequence and structure of these regulatory elements are surprisingly diverse. Even orthologous genes in related organisms are controlled by unrelated RNATs, and this is also the case for the *ompA* gene. While the *Shigella ompA* transcript is regulated by a fourU thermometer (Murphy et al., 2020), the RNAT upstream of *ompA* in *Y. pseudotuberculosis* presented here is structurally disparate but functionally equivalent.

Like *Shigella*, *Y. pseudotuberculosis* is a notorious foodborne pathogen causing gut-associated diseases. A considerable number of *Yersinia* virulence genes are temperature regulated, often by riboregulatory processes (Knickel et al., 2018). We identified a very promising RNAT upstream of *ompA* by a global RNA structuromics approach, in which *Y. pseudotuberculosis* RNA structures were probed at three different temperatures (Righetti et al., 2016). Here, we set out to study the structure-function relationship of this temperature-labile element and show that it is a functional RNAT allowing induction of OmpA levels at increasing temperature.

### Plasmid Construction

All utilized oligonucleotides and plasmids are summarized in Tables 2 and 3, respectively. Point mutations were generated by site-directed mutagenesis according to the instruction manual of the QuickChange® mutagenesis kit (Agilent Technologies).

The *ompA* RNAT-*bgaB* fusion plasmid (pBO4435) was constructed by first amplifying the YPK_2630 (*ompA*) 5'-UTR including 30 bp of the *ompA* coding region (108 bp) with primer pairs *ompA* UTR fw/*ompA* UTR rev, digested with NheI and EcoRI and ligated into pBAD2. The repressed *ompA* RNAT-*bgaB* (U38UC) fusion was constructed by site-directed mutagenesis with primer pair *ompA* rep fw/*ompA* rep rev using pBO4435 as a template.

The runoff plasmid for *in vitro* transcription of the *ompA* RNAT (pBO4920) was constructed by blunt-end ligation of a PCR-amplified DNA fragment (primer pair *ompA* ro fw/*ompA* ro rev), comprising the T7 RNA polymerase promoter, and the *ompA* RNAT including 30 bp of the *ompA* coding region, into the EcoRV restriction site of pUC18. Insertion of the repressive mutation (U38UC) into pBO4920 was achieved by site-directed mutagenesis (primer pair *ompA* rep fw/*ompA* rep rev).

Reporter Gene Activity Assay

Escherichia coli DH5α or Y. pseudotuberculosis YPIII cells carrying the ompA RNAT-bgaB fusion plasmids were grown overnight in LB supplemented with ampicillin at 25°C. Before being inoculated with an overnight culture to an optical density at 600 nm (OD_{600}) of 0.1, LB media supplemented with ampicillin were pre-warmed to 25°C. After growth to an OD_{600} of 0.5, transcription was induced with 0.01% (E. coli) or 0.1% for (Y. pseudotuberculosis) L-arabinose, respectively. The culture was split and shifted to pre-warmed 100 ml flasks. After incubation for 30 min, 400 µl samples was subsequently taken for β-galactosidase assay, 2 ml samples for Western blotting, and 4 ml samples for RNA isolation. The β-galactosidase assay was carried out as described previously (Gaubig et al., 2011; Righetti et al., 2016).

Western Blot Analysis

Cell pellets were resuspended in 1 × SDS sample buffer (2% SDS, 0.1% bromophenol blue, 1% 2-mercaptoethanol, 25% glycerol, 50 mM Tris/HCl, and pH 6.8) according to their
optical density (100 μl per OD_{600} of 1). After boiling for 10 min at 95°C, samples were centrifugated (10 min, 13,000 rpm) and the supernatant was separated by SDS gel electrophoresis in 5% stacking and 12% separating gels. Size-separated proteins were transferred by tank blotting onto a nitrocellulose membrane (Hybond-C Extra, GE Healthcare). An anti-His-HRP conjugate antibody (Bio-Rad) was used in a 1:4,000 dilution. Luminescence signals were detected by incubating membranes with Immobilon Forte Western HRP substrate (Millipore) and the FluorChem SP (Alpha Innotech).

RNA Extraction and Quantitative Reverse Transcription PCR

Total RNA was extracted using the peqGOLD TriFast reagent according to the manufacturer’s protocol. RNA samples were treated with Turbo™ DNase (TURBO DNA-free™ Kit, Invitrogen) to remove DNA contamination. cDNA synthesis was performed using the iScript™ cDNA synthesis Kit (Bio-Rad) according to the manufacturer’s protocol with 1 μg RNA per reaction. 2 μl of 1:10 diluted cDNA was mixed with 250 nM of each primer, 5 μl of 2× iTag Universal SYBR Green Supermix, and 2.5 μl sterile water (Carl Roth). Amplification and detection were performed in a CFX Connect™ Real-Time System (Bio-Rad). Standard curves were used to calculate primer efficiency and determine the linear range of amplification. Relative transcript amounts were calculated using the primer efficiency corrected method (Pfaffl, 2001). The non-thermoregulated reference genes gyrB and nuoB were used for normalization.

In vitro Transcription

RNA for RNA structure probing and primer extension inhibition experiments were synthesized in vitro by runoff transcription with T7 RNA polymerase (Thermo Scientific) from EcoRV-linearized plasmids (listed in Table 3) as previously described (Righetti et al., 2016).

Enzymatic RNA Structure Probing

RNA structure probing of the 5’-UTR and 30 nt of ompA was performed as described previously (Twittenhoff et al., 2020b). Briefly, in vitro transcribed and 5’-[32P]-labeled RNA (3,000 cpm) was mixed with buffer and tRNAs, preincubiated for 5 min at the respective temperature, and treated with T1 (0.0017U; Invitrogen) or T2 (0.056U; MoBiTec) RNases for 5 min. For digestion with RNase T1 and RNase T2, a 5 × TN buffer (100 mM Tris acetate, pH 7, and 500 mM NaCl) was used. An alkaline hydrolysis ladder was prepared as described in Brantl and Wagner (1994), meaning 60,000 cpm of labeled RNA was mixed with tRNAs and ladder buffer (1M Na2CO3 and 1M NaHCO3; pH 9) incubated for 2 min at 90°C. The T1 ladder was generated by using 30,000 cpm-labeled RNA. The samples were heated with 2 μl sequencing buffer (provided with RNase T1) at 90°C. Afterward, the RNA was incubated with the T1 RNase for 5 min at 37°C. All reactions were stopped by the addition of formamide loading dye and denaturation at 95°C.

Primer Extension Inhibition Analysis (Toeprinting)

Toeprinting analysis was performed with 30S ribosomal subunits, in vitro transcribed RNA, and tRNA_{32} (Sigma-Aldrich) according to a protocol as described before (Hartz et al., 1988). The 5’-[32P]-labeled oligonucleotide ompA_ro_rv, complementary to the 3’ end of the ompA mRNA, was used as a primer for cDNA synthesis. The radiolabeled primer (0.16 pmol) was annealed to the ompA mRNA (0.08 pmol) and incubated with 30S ribosomal subunits (24 pmol) or Watanabe buffer [60 mM HEPES/KOH, 10.5 mM Mg(CH3COO)2, 690 mM NH4COO, 12 mM 2-mercaptopethanol, 10 mM spermidine, and 0.25 mM spermine] in the presence of tRNA_{32} (8 pmol) at 25, 37, or 42°C for 10 min. After the addition of 2 μl MMLV-Mix [VD+Mg2+ buffer, BSA, dNTPs, and 800 U MMLV reverse transcriptase (Invitrogen)], cDNA synthesis was performed for 10 min at 37°C. The reaction was stopped by the addition of formamide loading dye, and the samples were separated on an 8% denaturing polyacrylamide gel. The Thermo Sequenase Cycle Sequencing Kit (Applied Biosystems) was used for sequencing reactions with plasmid pBO4920 as a template and radiolabeled primer ompA_ro_rv.

RESULTS

The ompA 5’-UTR Contains a Thermoresponsive RNA Structure, Which Facilitates Temperature-Dependent Regulation

A previously conducted global in vitro RNA structure probing analysis (Righetti et al., 2016) provided strong evidence for the existence of temperature-sensitive RNA structures in the 5’-UTRs of numerous mRNAs. One of the top candidates (rank #3 of chromosomally encoded mRNAs) discovered by this parallel analysis of RNA structures approach was the 5’-UTR of ompA. The RNA structure observed at 25°C was destabilized at higher temperatures (Figure 1A). This was especially prominent in the region around the SD sequence and in the early coding region. Here, the PARS profile dropped from positive to negative values indicative of a transition from a double-stranded (ds) to single-stranded (ss) conformation. This behavior is typical of zipper-like RNATs that facilitate ribosome binding at elevated temperatures (Kortmann and Narberhaus, 2012). The PARS analysis revealed an almost completely folded ompA 5’-UTR that is engaged in several stem-loop structures (Figure 1B). Strikingly, the SD sequence (53-GGAG-56) is imperfectly paired and contains a bulged adenine. It is very likely that this mismatched nucleotide in concert with four unpaired nucleotides (58-GUAA-61) between the SD sequence and the AUG start codon is key to the temperature sensitivity of this 5’-UTR.

To examine the regulation of ompA in detail, we first checked, whether transcription of the gene is temperature-controlled by performing qRT-PCR on total RNA samples from Y. pseudotuberculosis YPIII after growth at 25 and 37°C (Figure 1C). Consistent with already existing RNA-seq results (Nuss et al., 2015),
we observed a fold change around 0.6 (37 vs. 25°C) showing a reduction in ompA mRNA at a higher temperature.

The RNA structurome data, in contrast, suggested an upregulation of OmpA protein at 37°C due to the thermoresponsive nature of the ompA 5'-UTR. To test this hypothesis, we translationally fused the ompA 5'-UTR to the bgaB gene coding for a heat-stable His-tagged β-galactosidase downstream of the arabinose-inducible P_{BAD} promotor and measured the β-galactosidase activity and protein amounts at 25°C and after a shift to 37 or 42°C. The well-studied lcrF RNAT of Y. pseudotuberculosis served as a positive control (Figure 1D).

A clear increase in β-galactosidase activity and protein amount after the temperature shift supported the existence of a functional RNAT upstream of ompA able to confer translational repression at 25°C and induction at 37 or 42°C.

A Stabilizing Point Mutation Prevents RNAT Regulation

One way of verifying the contribution of a temperature-sensitive RNA structure in translational control is the construction of a stabilized version. Based on the PARS-derived secondary structure,
we introduced a cytosine between U38 and A39 (called U38UC or “rep” for repressed variant) in the anti-SD sequence leading to a perfectly paired SD sequence without any mismatches (Figure 2A). The increased thermodynamic stability should prevent the RNA structure from melting at higher temperatures and thereby abolish RNAT functionality. Indeed, reporter gene assays revealed the absence of β-galactosidase protein and activity at 25 and 37°C in E. coli as well as in Y. pseudotuberculosis (Figure 2B). Apparently, the introduction of just one additional base pair was sufficient to abolish the temperature regulation. To solidify our claim that the 5’-UTR regulates translation (and not transcription or mRNA degradation), we analyzed the bgaB mRNA levels in all three tested Y. pseudotuberculosis strains by qRT-PCR and found that the transcript levels were the same at 25 and 37°C (Figure 2C).

The ompA RNAT Opens at Higher Temperatures Around the SD Region

Next, we examined the structure and temperature-induced conformational changes in the RNAT by enzymatic RNA structure probing using in vitro transcribed and 5’ end-labeled ompA RNA at 25, 37, and 42°C treated with RNases T1 (preferentially cleaves at unpaired guanines) and T2 (preferentially cleaves at unpaired adenines but also other ss residues; Figure 3A). The cleavage pattern supported the overall structure of the ompA 5’-UTR by prominent cleavage at 25°C in apical loops (e.g., C80 and G81). In accordance with the dynamic PARS-derived secondary structure (Figures 1A, 3B), residues around the SD sequence were sensitized against RNase cleavage at higher temperatures due to melting of the secondary structure. For example, nucleotides G53 and G55

**Figure 2** | Mutation of the anti-SD sequence locks the RNAT in a closed conformation. (A) PARS-derived secondary structure of the ompA RNAT stem and the predicted stabilized structure at 25°C. The potential SD sequence is highlighted in yellow, the mutation site of the anti-SD sequence in red and the AUG in blue. (B) Translational control was measured by bgaB fusions. A schematic representation of the reporter gene fusion is displayed. The ompA RNAT was translationally fused to bgaB under control of the P_{bad} promoter. Additionally, a point mutation (U38UC) was introduced to stabilize the RNAT (rep). As a control, the lcrF RNAT fusion was used. The fusion plasmids were introduced into E. coli and Y. pseudotuberculosis YPIII cells and grown to an OD_{600} of 0.5 at 25°C. Subsequently, transcription was induced by the addition of 0.01% for E. coli or 0.1% for Y. pseudotuberculosis L-arabinose and the cultures were split and transferred into pre-warmed flask at 25 and 37°C, respectively. After 30 min of incubation, samples were taken for β-galactosidase assays, Western blot analysis, and qRT-PCR. Experiments were carried out in biological triplicates. Mean and corresponding standard deviations are shown. Western blot membranes were stained with Ponceau S as a loading control. One representative Western blot is shown. Analysis was carried out in biological triplicates. (C) Comparison of bgaB transcript amount between 37 and 25°C by qRT-PCR of exponentially grown YPIII cells harboring the ompA RNAT-bgaB fusion plasmids at 25 and 37°C, respectively. For qRT-PCR, the obtained data were normalized to gyrB and nuoB. qRT-PCR was prepared in biological triplicates and technical triplicates.
were almost untouched by T1 at 25°C but efficiently cleaved at 37 and 42°C. Residual cleavage of the bulged A54 by T2 at 25°C massively increased at 37 and 42°C making it the most prominent cleavage product at high temperatures. Fully consistent with the reporter gene assays (Figure 2), the SD sequence of the rep variant was almost completely inaccessible to RNase cleavage demonstrating that melting of the RNAT is prevented by the point mutation, which locks the structure in a closed conformation.

**The Ribosome Gains Access to the ompA Transcript at 37°C**

The observed melting of the *ompA* 5'-UTR at higher temperatures (Figures 1A, 3) together with the reporter gene studies (Figures 1D, 2) strongly suggested increased translation initiation at higher temperatures. We employed primer extension inhibition assays (toeprinting) to demonstrate ribosome binding. *In vitro* transcribed *ompA* RNA was reversely transcribed from a radiolabeled oligonucleotide in the presence or absence of 30S ribosomal subunits at 25 and 37°C. Ribosomes bound to the mRNA are stabilized in a ternary complex with tRNA<sub>fMet</sub> and act as a roadblock for reverse transcription. This leads to premature termination of reverse transcription and thus shorter fragments (toeprints). As expected, in the presence of ribosomes, the toeprint signals in the appropriate distance from the AUG start codon were weak at 25°C but strong at 37°C (Figure 4). No toeprint signal, i.e., no ribosome binding, was found when the stabilized rep version was assayed. Instead, termination products independent of the presence of ribosomes appeared within the codon sequence, a phenomenon frequently observed downstream (considering the...
direction of the reverse transcriptase) of stable structures in stabilized RNATs (Böhme et al., 2012; Twittenhoff et al., 2020b).

**DISCUSSION**

Sensing of and rapidly responding to the sudden external changes associated with host infection is crucial for enteric pathogens like *Y. pseudotuberculosis*. One parameter that predictably and reversibly changes during the transitions from the environment to a warm-blooded host and back into the environment is temperature. A fast and efficient way to reversibly modulate gene expression in response to temperature shifts is zipper-like RNATs because the mRNA is already available for translation (Grosso-Becera et al., 2015; Wei and Murphy, 2016; Loh et al., 2018). *This is certainly the reason why RNATs are extremely widespread posttranscriptional control elements in numerous bacterial pathogens (Hoe and Goguen, 1993; Johansson et al., 2002; Böhme et al., 2012; Kouse et al., 2013; Loh et al., 2013; Weber et al., 2014; Wei et al., 2017; Twittenhoff et al., 2020a,b; Brewer et al., 2021).*

Here, we describe the structural and functional features of an RNAT in the *Y. pseudotuberculosis* ompA transcript that was one of the prime candidates in our previous PARS study (Righetti et al., 2016). We were particularly interested in this candidate because a recent report demonstrated

![Figure 4](image-url)
RNAT-controlled translation of ompA in S. dysenteriae (Murphy et al., 2020). Despite regulating the same gene, it is important to note that the Yersinia and Shigella RNATs are very different with respect to length, sequence, and structure. First, the S. dysenteriae ompA 5′-UTR is 133 nucleotides long, and the last 35 residues are sufficient to confer translational control. In contrast, the RNAT from Y. pseudotuberculosis is 92 nucleotides long and more densely folded. Second, the S. dysenteriae RNAT belongs to the fourU family showing the characteristic complementarity of the SD sequence to four consecutive uracil residues (Waldminghaus et al., 2007). The Y. pseudotuberculosis RNAT is not a member of this family. The inherent temperature lability is due to a bulged adenine residue in the center of the SD sequence, which pairs imperfectly with an anti-SD sequence comprised of CCUA. Introducing one additional residue that pairs with the exposed adenine completely eliminated the expression and heat induction even when sufficient ompA mRNA was present. This demonstrates the relevance of precisely balanced structural features in a functional RNAT to respond within the virulence-relevant temperature regime. Overall, the ompA thermometer is another interesting example of convergent evolution of RNATs as has previously been proposed for the regulation of CnfY-type toxins (Twittenhoff et al., 2020b).

Many enterobacterial outer membrane protein genes are under tight posttranscriptional regulation (Guillier et al., 2006; Vogel and Pappenfort, 2006). A highly conserved sRNA also believed to control ompA in Yersinia species is MicA (Udekwu et al., 2005). It binds across the SD sequence and prevents ribosome binding, which facilitates RNaseE-mediated cleavage. The temperature-induced structural transition of the ompA 5′-UTR from a closed to an open conformation potentially adds another layer of posttranscriptional control. Under circumstances when MicA is abundant, the sRNA might interfere with translation initiation. The exact interplay between the ompA thermosensor, MicA (and maybe other sRNAs), the RNA chaperone Hfq, and RNases is not yet understood. The situation, however, is somewhat reminiscent of the Listeria pylA thermometer that – in its open form – is able to interact with the two sRNAs, SreA and SreB, which decreases the level of PrfA and thereby links virulence gene expression to nutrient availability (Loh et al., 2009).

Having OmpA under temperature regulation supports its role as a virulence factor. There is growing evidence that the outer membrane protein is involved in many pathogenesis-related processes in diverse Gram-negative bacteria (Krishnan and Prasadara, 2012). It is involved in adherence to epithelial cells (Smith et al., 2007; Gaddy et al., 2009), mouse mortality (Sánchez-Encinuales et al., 2017), and biofilm formation (Weiser and Gotschlich, 1991; Azghani et al., 2002). OmpA of pathogenic Yersinia species is a highly immunogenic protein and may be an excellent vaccine candidate, due to its cross-immunogenicity and intense immune response among Yersinia species (Chen et al., 2015). Furthermore, Y. pestis and Y. pseudotuberculosis ompA mutants are defective in surviving in macrophages, and the Y. pestis mutant is outcompeted by the wild-type strain in a mouse-infection model (Bartra et al., 2012).

Given the importance of OmpA for efficient pathogenesis, it may be a promising target for treatment of infections caused by Gram-negative bacteria. A recently identified OmpA inhibitor, cyclic hexapeptide AOA-2, inhibits adherence to eukaryotic cells and biofilm formation (Vila-Farrés et al., 2017). The compound attenuates virulence by reducing the dissemination between organs and decreases mouse mortality after A. baumannii, E. coli, and Pseudomonas aeruginosa infections. In combination with other antimicrobial agents, OmpA inhibitors might be helpful for combating multidrug-resistant bacteria and thereby reducing mortality caused by infections with Gram-negative pathogens.

A recent study on OmpA in Acinetobacter sp. linked ompA expression to oxidative stress (Shahryari et al., 2021). The authors suggested a protective effect by the poor permeability of the slows OmpA porin compared to other outer membrane proteins, such as OmpC, which is known to produce larger pores, at least in Salmonella (van der Heijden et al., 2016). A connection between OmpA and oxidative stress is interesting since pathogens are typically exposed to a multitude of reactive oxygen species (ROS) upon infection of a host. An intriguing finding of our RNA structurome analyses is the presence of potential RNATs upstream of various oxidative stress response genes (Righetti et al., 2016; Twittenhoff et al., 2020a). This is unlikely to be a coincidence and suggests parallel ways of host-body temperature-induced protective measures against ROS attack. Following up on RNAT-mediated control of genes combating ROS in pathogenic bacteria might be a worthwhile subject of future studies.

DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

AUTHOR CONTRIBUTIONS
