Abstract: We describe on-shell methods for computing one- and two-loop anomalous dimensions in the context of effective field theories containing higher-dimension operators. We also summarize methods for computing one-loop amplitudes, which are used as inputs to the computation of two-loop anomalous dimensions, and we explain how the structure of rational terms and judicious renormalization scheme choices can lead to additional vanishing terms in the anomalous dimension matrix at two loops. We describe the two-loop implications for the Standard Model Effective Field Theory (SMEFT). As a by-product of this analysis we verify a variety of one-loop SMEFT anomalous dimensions computed by Alonso, Jenkins, Manohar and Trott.
1 Introduction

Effective Field Theory (EFT) approaches have risen to prominence in recent years as a systematic means for quantifying new physics beyond the Standard Model. The Standard Model Effective Field Theory (SMEFT) incorporates the effects of new physics via higher-dimension operators built from Standard Model fields [1, 2]. The operators are organized according to their dimension, which gives a measure of their importance at low-energy scales. The SMEFT allows exploration of the effects of new physics without requiring a complete understanding of the more fundamental high-energy theory. While systematic, the SMEFT involves a large number of operators and free coefficients [3], making it useful to develop improved techniques for computing quantities of physical interest and for understanding their structure. One such quantity is the anomalous dimension matrix of the higher-dimension operators. The appearance of anomalous dimensions implies that the Wilson coefficients of operators at scales accessible by collider experiments differ from those at the high-energy matching scale to the more fundamental unknown theory. These also control operator mixing, providing important information on how experimental constraints from one operator affect the coefficients of other operators. This makes evaluating the anomalous dimension matrix a crucial aspect of interpreting results within the SMEFT. Towards this goal, here we apply on-shell methods that greatly streamline the computation of anomalous dimensions at one and two loops and expose hidden structure.

A systematic and complete computation of the one-loop anomalous dimension matrix for dimension-six operators in the SMEFT is found in the landmark calculations of Refs. [4]. Besides their importance for interpreting experimental data, these calculations reveal a remarkable structure with the appearance of nontrivial zeros in the anomalous dimension matrix [5]. These one-loop zeros have been understood as stemming from selection rules that arise from supersymmetry embeddings [6], helicity [7], operator lengths [8], and angular momentum [9]. Perhaps even more surprisingly, nontrivial zeros in the anomalous dimension matrix of the SMEFT appear at any loop order and for operators of any dimension [8]. In addition, a surprising number of the associated one-loop scattering amplitudes vanish as well [9, 10], suggesting additional zeros may appear in the anomalous dimensions at two loops. Here we apply on-shell methods to identify a new set of vanishing terms in the two-loop anomalous dimension matrix of the SMEFT. As a by product of our two-loop study, we also confirm many one-loop anomalous dimensions computed in Refs. [4], via both the generalized unitarity method [11] and an elegant new unitarity-based method due to Caron-Huot and Wilhelm for directly extracting anomalous dimensions from cuts [12], which builds on insight developed in earlier work on $\mathcal{N} = 4$ super-Yang-Mills theory [13].

On-shell methods have proven to be quite useful in a variety of other settings, including collider physics (see e.g. Refs. [14]), ultraviolet properties of (super)gravity
(see e.g. Refs. [15–18]), theoretical explorations of supersymmetric gauge and gravity theories (see e.g. Refs. [19, 20]), cosmological observables (see e.g. Refs. [21, 22]), and gravitational-wave physics (see e.g. Refs. [23]). They have also been used as a convenient means for classifying interactions in EFTs such as the SMEFT [24]. In addition, general properties of the S-matrix, such as unitarity, causality and analyticity have been used to constrain Wilson coefficients of EFTs [25], including the SMEFT [26].

In the context of anomalous dimensions and renormalization-group analyses, unitarity cuts give us direct access to renormalization-scale dependence. After subtracting infrared singularities, the renormalization-scale dependence can be read off from remaining dimensional imbalances in the arguments of logarithms [16]. The direct link between anomalous dimensions at any loop order and unitarity cuts is made explicit in the formulation of Caron-Huot and Wilhelm [12]. In carrying out our two-loop analysis we make extensive use of their formulation. Very recently the same formalism and general set of ideas was applied in Refs. [27, 28] to compute certain SMEFT anomalous dimensions.

In general, two-loop unitarity cuts include both three-particle cuts between two tree-level objects, as well as two-particle cuts between tree-level and one-loop objects. Consequently, our exploration of two-loop anomalous dimensions will require computing one-loop matrix elements first. On-shell methods, in particular generalized unitary [11, 29, 30], are especially well suited for this task. Because we feed one-loop matrix elements into higher-loop calculations, we find it convenient to use $D$-dimensional techniques which account for rational terms. To carry out the integration, we decompose the integrands into gauge-invariant tensors along the lines of Refs. [31, 32]. In this form, the integrands can be straightforwardly reduced to a basis of scalar integrals using integration by parts technology (as implemented, e.g., in FIRE [33]). These one-loop amplitudes are among the building blocks that feed into the two-loop anomalous dimension calculation.

Using the unitarity-based formalism, we indeed find that many potential contributions to the two-loop anomalous dimension matrix vanish for a variety of reasons, including the appearance of only scaleless integrals [8], color selection rules, vanishing rational terms at one loop, as well as appropriate renormalization scheme choices at one loop. These vanishing contributions go beyond those identified in our previous paper [8]. Of the new vanishings, perhaps the most surprising is the finding that additional zeros can be induced at two loops by slightly adjusting the $\overline{\text{MS}}$ renormalization scheme at one loop. This is tied to the fact that two-loop anomalous dimensions and local rational contributions to one-loop amplitudes are scheme dependent, and can therefore be set to zero by appropriate finite shifts of operator coefficients, or, equivalently, by a finite renormalization of the operators, or the addition of finite local counterterms.

For simplicity, we use a non-chiral version of the Standard Model, with zero quark
masses and Yukawa couplings and without an Abelian sector, but point out overlap with the SMEFT. We note that although we only utilize Dirac fermions here, on-shell methods are well suited for dealing with chiral fermions as well (see e.g. Refs. [14, 29]). In any case, this model is a close enough cousin of the SMEFT that we can directly compare to a variety of one-loop SMEFT anomalous dimensions calculated in Refs. [4] and make some predictions about the structure of the two-loop anomalous dimension matrix. (See Section 5 and in particular Table 6.)

The paper is organized as follows. In Section 2, we explain our conventions, list the higher-dimensional operators in our simplified version of the SMEFT, and summarize the on-shell methods that we use to obtain anomalous dimensions. In Section 3 we explain the use of generalized unitarity in constructing full one-loop amplitudes, and we discuss the appearance of numerous zeros in the rational terms of the amplitudes. We also explain how finite counterterms can produce additional zeros in the rational terms of many of the one-loop amplitudes. Examples of additional vanishing contributions to the two-loop anomalous dimension matrix are presented in Section 4, including those that arise from finite counterterms at one-loop. In Section 5 we discuss the overlap between our simplified model and the full SMEFT in the basis of operators used in Refs. [4], and discuss the implications of our results for the latter theory. We give our conclusions in Section 6. Appendix A explains the projection method used for integration in detail and lists the gauge invariant basis tensors. The explicit $D$-dimensional forms of the full one-loop amplitudes, as well as their four-dimensional finite remainders, are relegated to the ancillary files [34] and Appendix B, respectively.

2 Setup and formalism

We now present our conventions and explain the on-shell formalisms that we use for obtaining the anomalous dimensions. One procedure for doing so is to extract them from ultraviolet divergences in amplitudes. This procedure follows the generalized unitarity method for assembling scattering amplitudes from their unitarity cuts [11, 11, 14, 29]. While we describe the procedure for obtaining the anomalous dimensions in the current section, we leave a more detailed discussion of the generalized unitarity method for Section 3, where it will be used to construct full amplitudes.

As a second method, we apply the recent formalism of Caron-Huot and Wilhelm [12], which directly expresses the anomalous dimensions in terms of unitarity cuts. This method is particularly effective for computing anomalous dimensions, and is our preferred method beyond one loop. We show how this method helps clarify the structure of the anomalous dimension matrix at two loops and exposes new nontrivial zeros.
2.1 Conventions and basic setup

To illustrate our methods we will consider a model with dimension-four Lagrangian given by

\[ L^{(4)} = -\frac{1}{4} F_{\mu\nu}^a F^{a\mu\nu} + D_\mu \varphi \, D^\mu \varphi - \lambda (\varphi \varphi)^2 + i \sum_{m=1}^{N_f} \bar{\psi}_m \gamma^\mu \psi_m, \quad (2.1) \]

where the gauge field strength, \( F_{\mu\nu}^a \), is in the adjoint representation of \( SU(N) \), while \( \psi_m \) and \( \varphi \) are fundamental representation Dirac fermions and scalars, respectively. The index \( m \) on the fermions denotes the flavor; for simplicity we take a single flavor of scalars. The covariant derivative is given by

\[ (D_\mu \psi_m)_i = \left( \delta_{ij} \partial_\mu + ig \frac{1}{\sqrt{2}} T^a_{ij} A^a_\mu \right) (\psi_m)_j, \quad (2.2) \]

where \( T^a_{ij} \) is the \( SU(N) \) generator. We normalize the generator in the standard amplitudes convention by \( \text{Tr}[T^a T^b] = \delta^{ab} \) which differs from the usual textbook one, and we define \( f^{abc} = -i \text{Tr}[(T^a, T^b)T^c] \) and \( d^{abc} = \text{Tr}\{T^a, T^b\}T^c\) for later use.\(^1\)

This model theory has the general structure of the Standard Model, but with all masses and Yukawa couplings set to zero, and with only one gauge group. Here we also use Dirac instead of chiral fermions; the basic methods apply just as well to cases which include chiral fermions in the context of Standard Model calculations, as in Ref. [29].

To mimic the SMEFT we modify this Lagrangian by adding dimension-six operators supressed by a high-energy scale \( \Lambda \):

\[ L = L^{(4)} + \frac{1}{\Lambda^2} \sum_k c_i^{(6)} O^{(6)}_i, \quad (2.3) \]

where the list of the operators that we consider here is given in Table 1\(^2\). Note that our simplified model contains representatives from all of the operator classes of the basis used in Refs. [4], other than the classes \( \psi^2 F \varphi \) and \( \psi^2 \varphi^3 \) \( (\psi^2 X H \) and \( \psi^2 H^3 \) in the notation of Refs. [4]), since operators in these classes must always have one uncharged fermion. We defer a comparison to the full SMEFT to Section 5.

At first order in \( c_i/\Lambda^2 \), renormalization induces mixing of the dimension-six operators, as parametrized by

\[ \dot{c}_i \equiv \frac{\partial c_i}{\partial \log \mu} = c_j \gamma_{ji}. \quad (2.4) \]

If the coefficient of operator \( O_j \) appears on the right-hand side of the RG equation for the coefficient of operator \( O_i \), as above, we say that \( O_j \) renormalizes \( O_i \), or that

\(^1\)Note that our structure constants, \( f^{abc} \), carry an extra factor of \( \sqrt{2} \) relative to standard textbook conventions [35].

\(^2\)We note that \( O_{\varphi^6} \) has no nonzero four-point amplitudes through two-loops, and therefore cannot renormalize any of the other operators [8]. We still include it here for completeness.
Table 1. List of dimension-six operators considered here. For simplicity, we take the fermions to be Dirac. The labels $mnpr$ are flavor indices and $abc$ color indices. Note the operator $O_{F^3}$ is normalized slightly differently than in Refs. [4], as are the color matrices $T^a$ in the operators $O_{(D^2\varphi^4)_1}$ and $O_{(D^2\varphi^4)_2}$. We will occasionally drop the ( )$_1$ and ( )$_2$ subscripts to refer to pairs of operators collectively.

$$\begin{array}{ll}
\text{Label} & \text{Operator} \\
O_{F^3} & \frac{1}{3} f^{abc} F_{\mu\nu} F_{\nu\rho} F_{\rho\mu} \\
O_{(\varphi^2 F^2)_1} & (\varphi^\dagger \varphi) F_{\mu\nu} F_{\mu\nu} \\
O_{(\varphi^2 F^2)_2} & (\varphi^\dagger T^a \varphi) F_{\mu\nu} F_{\mu\nu} \\
O_{(D^2\varphi^4)_1} & (\varphi^\dagger D^\mu \varphi^* (\varphi^\dagger D_{\mu} \varphi) \\
O_{(D^2\varphi^4)_2} & (\varphi^\dagger \varphi) \Box (\varphi^\dagger \varphi) \\
O_{\varphi^6} & (\varphi^\dagger \varphi)^3 \\
O_{(D\varphi^2 \psi^2)_1}^{pr} & i(\varphi^\dagger (D_{\mu} - \slashed{D}_{\mu}) \varphi) (\bar{\psi}^r T^a \gamma^\mu \psi^r) \\
O_{(D\varphi^2 \psi^2)_2}^{pr} & i(\varphi^\dagger (T^a D_{\mu} - \slashed{D}_{\mu} T^a) \varphi) (\bar{\psi}^r T^a \gamma^\mu \psi^r) \\
O_{(\psi^4)_1}^{mnpr} & (\bar{\psi}^m \gamma^\mu \psi^m) (\bar{\psi}^p \gamma^\mu \psi^p) \\
O_{(\psi^4)_2}^{mnpr} & (\bar{\psi}^m \gamma^\mu T^a \psi^m) (\bar{\psi}^p \gamma^\mu T^a \psi^p) \\
\end{array}$$

they mix under renormalization. Sometimes we write the corresponding anomalous dimension as $\gamma_{ij}$. In all tables which describe anomalous dimensions we will display $\gamma'_{ij} = \gamma^T_{ij}$ to facilitate comparison with Refs. [4]. The anomalous dimension matrix $\gamma_{ij}$ depends on the dimension-four couplings $g$ and $\lambda$, in the combinations

$$\tilde{g}^2 = \frac{g^2}{(4\pi)^2}, \quad \tilde{\lambda} = \frac{\lambda}{(4\pi)^2},$$

which we sometimes refer to collectively as $g^{(4)}$.

We extract anomalous dimensions from both amplitudes and form factors. We define a form factor with an operator insertion as

$$F_i(1^{h_1}, ..., n^{h_n}; q) = \langle k_1^{h_1}, ..., k_n^{h_n} | O_i(q) | 0 \rangle,$$

which are matrix elements between an on-shell state $\langle k_1, ..., k_n |$, with particles of momenta $\{ k_1 ... k_n \}$ and helicities $\{ h_1 ... h_n \}$, and an operator $O_i$ that injects additional off-shell momentum $q$. The states might also be dependent on the color and flavor of the particles, but we leave this dependence implicit for the moment. Form factors are especially useful when dealing with on-shell states with fewer than four particles,
where kinematics would otherwise require the amplitude (with real momenta) to be zero. From the perspective of form factors, we can think of an amplitude with an operator insertion as a form factor, but where the higher-dimension operator injects zero momentum, \( q = 0 \),

\[
A_i(1^{h_1}, \ldots, n^{h_n}) = \langle k_1^{h_1}, \ldots, k_n^{h_n} | O_i(0) | 0 \rangle.
\]  

(2.7)

When the inserted operator is the identity, we recover the usual scattering amplitude, which depends only on the dimension-four couplings. We denote such an amplitude as

\[
A(1^{h_1}, \ldots, n^{h_n}) = \langle k_1^{h_1}, \ldots, k_n^{h_n} | 0 \rangle = \langle k_1^{h_1}, \ldots, k_i^{h_i} | \mathcal{M} | -k_i^{-h_i+1}, \ldots, -k_n^{-h_n} \rangle.
\]  

(2.8)

Unless otherwise stated, we use an all outgoing convention where all the particles are crossed to the final state. When crossing fermions there are additional signs on the right-hand side of Eq. (2.8) that we leave implicit here. In general we can write the form factors (and amplitudes) as color-space vectors,

\[
F_i(1, \ldots, n) = \sum_j C^{[ij]} F_{[ij]}(1, \ldots, n),
\]  

(2.9)

where the \( C^{[ij]} \) are a set of independent color factors. In the context of amplitudes, these correspond to color-ordered \([36]\) or, more generally, primitive \([37]\) amplitudes. The color factors \( C^{[ij]} \) depend on which particles of the amplitude are in the adjoint or fundamental representation of \( SU(N) \). Here, we only need the decomposition into a basis of color factors without using special properties of the coefficients. For the various processes we consider, the tree and one-loop amplitudes are listed in Appendix B.

We use the conventional dimensional regularization and \( \overline{\text{MS}} \)-like schemes throughout, in which the amplitudes and form factors, \( F_i \) satisfy the renormalization-group equations

\[
\left[ (\mu \partial_\mu + \beta \partial) \delta_{ij} + (\gamma_{ij}^{\text{UV}} - \gamma_{ij}^{\text{IR}}) \right] F_j = 0,
\]

(2.10)

where \( \partial_\mu := \partial / \partial \mu \), \( \partial := \partial / \partial g^{(4)} \), \( \beta := \beta(g^{(4)}) \) is the \( \beta \)-function of the collection of marginal couplings, \( \gamma_{ij}^{\text{UV}} \) are the anomalous dimensions of the higher-dimension operators, and \( \gamma_{ij}^{\text{IR}} \) are the IR anomalous dimensions, arising from soft and/or collinear divergences\(^3\). For later convenience, we introduce the shorthand

\[
\Delta \gamma = \gamma_{ij}^{\text{UV}} - \gamma_{ij}^{\text{IR}}.
\]

(2.11)

The appearance of both kinds of anomalous dimensions stems from the fact that there is a single dimensional-regularization parameter, \( \epsilon = \epsilon_{\text{UV}} = \epsilon_{\text{IR}} \), and single scale, \( \mu = \mu_{\text{UV}} = \mu_{\text{IR}} \), for both the UV and IR divergences. As usual we take \( \epsilon = (4 - D)/2 \).

\(^3\)The relative sign between UV and IR anomalous dimensions is merely a convention.
The perturbative expansion of the different quantities we consider is denoted by

\[ F_i = F_i^{(0)} + F_i^{(1)} + F_i^{(2)} + \cdots, \]
\[ A_i = A_i^{(0)} + A_i^{(1)} + A_i^{(2)} + \cdots, \]
\[ \gamma_{ij} = \gamma_{ij}^{(1)} + \gamma_{ij}^{(2)} + \cdots, \]
\[ \beta = \beta^{(1)} + \beta^{(2)} + \cdots, \]

(2.12)

where each order in the expansion includes an additional power of the dimension-four couplings, \( g^{(4)} \), as defined in Eq. (2.5), compared to the previous order. Since the operators we consider here have at least four fields, except for the \( F^3 \) case, any of the generated four-point tree amplitudes are local, and directly correspond to the operator. The amplitudes generated by the \( F^3 \) operator also contain a vertex obtained from the dimension-four operators. Thus, the four-point tree amplitudes have no powers of \( g^{(4)} \), with the exception of the four-point amplitudes generated from the \( F^3 \) operator.

2.2 Anomalous dimensions from UV divergences

Anomalous dimensions are traditionally extracted from counterterms associated to UV divergences. For instance, in Refs. [4] the full one-loop anomalous dimension matrix of the SMEFT was calculated by extracting the \( 1/\epsilon \) divergences of the one-particle irreducible (1PI) diagrams that generate the one-loop effective action in the background field method. Alternatively, one might extract the anomalous dimensions from on-shell amplitudes. Here, we use the full one-loop amplitudes to calculate the one-loop anomalous dimension matrix of our model, and thereby verify a representative set of the anomalous dimensions calculated in Refs. [4].

An efficient way of determining UV divergences at one loop was presented for the \( \beta \)-function in Ref. [38]. Here we adopt this method to calculate one-loop anomalous dimensions. In general, the renormalization of \( \mathcal{O}_i \) by \( \mathcal{O}_j \) at one loop is determined by calculating the matrix element with external particles corresponding to \( \mathcal{O}_i \), but with an insertion of \( \mathcal{O}_j \). In general, one-loop matrix elements can be expressed in terms of a basis of scalar integrals

\[ A_i^{(1)} = \sum_s a_{4,s}^s I_{4,s} + \sum_s a_{3,s}^s I_{3,s} + \sum_s a_{2,s}^s I_{2,s}, \]

(2.13)

comprised of boxes \( I_{4,s} \), triangles, \( I_{3,s} \), and bubbles, \( I_{2,s} \), where the corresponding coefficients, \( a_{4,s}^s, b_i^s \) and \( c_i \) are gauge invariant and generically depend on color and the dimensional regularization parameter \( \epsilon \). The integrals can then be expanded in \( \epsilon \), producing both UV and IR poles in \( \epsilon \). Only the scalar bubble integrals contain UV divergences, so we write a formula for the anomalous dimensions in terms of the bubble coefficients \( a_{2,i}^s \), whose \( \epsilon \) dependence can be ignored for this purpose. However, some
care is required because of cancellations between UV and IR divergences. We delay a
detailed discussion of the infrared structure of the amplitudes to Section 3. For the
moment, we just recall that the $1/\epsilon$ pole in the bubble integrals in Eq. (2.13) does not
contain the full UV divergence of the amplitude. The reason for this is that there is
an additional $1/\epsilon$ pole which originates in bubble-on-external-leg diagrams, which are
scaleless and set to zero in dimensional regularization because of a cancellation of UV
and IR poles,

$$p \quad \left|_{p^2=0} \right. \propto \frac{1}{\epsilon_{\text{UV}}} - \frac{1}{\epsilon_{\text{IR}}} + \log \frac{\mu_{\text{UV}}^2}{\mu_{\text{IR}}^2}. \quad (2.14)$$

Hence the bubbles on external legs give an additional UV contribution,

$$-\frac{1}{2\epsilon} \gamma_{c,p}^{\text{IR}(1)} A_i^{(0)} := -\frac{1}{2\epsilon} \sum_p \gamma_{c,p}^{\text{IR}} A_i^{(0)}, \quad (2.15)$$

where $\gamma_{c,p}^{\text{IR}}$ is the so-called collinear anomalous dimension of particle $p$, and the sum is
over all external states of the tree amplitude. For the vectors, fermions and scalars in
our theory the collinear anomalous dimensions are given by [39]

$$\gamma_{c,v}^{\text{IR}(1)} = -\tilde{g}^2 b_0, \quad \gamma_{c,f}^{\text{IR}(1)} = -\tilde{g}^2 3C_F, \quad \gamma_{c,s}^{\text{IR}(1)} = -\tilde{g}^2 4C_F, \quad (2.16)$$

where $b_0 = (11N - 2N_f - N_s/2)/3$ is the coefficient in the one-loop $\beta$-function of $g$,
and $C_F = (N^2 - 1)/2N$ is the Casimir of the fundamental representation. While we
only consider one flavor of scalar in our model, we include the parameter $N_s$ in the
$\beta$-function and elsewhere to track contributions from scalar loops.

In addition, there are contributions to the $1/\epsilon$ UV pole proportional to the one-
loop $\beta$-function of the dimension-four couplings, related to the renormalization of such
couplings

$$\frac{1}{2\epsilon} (n - L_i) \tilde{\beta}^{(1)} A_i^{(0)}, \quad (2.17)$$

where $\tilde{\beta}^{(1)} = \beta^{(1)}/g^{(4)}$, $n$ is the number of external states and $L_i$ is the length of the
operator $O_i$, i.e., the number of fields it contains. We therefore conclude that the sum
over bubble coefficients is related to the UV anomalous dimensions by

$$\frac{1}{(4\pi)^2} \sum_s a_{s,i}^2 = -\frac{1}{2} \left[ \gamma_{ij}^{\text{UV}} - \gamma_{c,ij}^{\text{IR}} \delta_{ij} + (n - L_i) \tilde{\beta}^{(1)} \delta_{ij} \right] A_j^{(0)}. \quad (2.18)$$

Similar formulas have recently been used in Ref. [28]. There are multiple methods by
which one might calculate these coefficients. We do so by using generalized unitar-
ity. For the purposes of extracting the UV divergences, it suffices to evaluate four-
dimensional cuts [7, 38]. However, we are interested in obtaining the full amplitudes,
including rational terms, as a stepping stone towards calculating two-loop anomalous
dimensions, so we use $D$-dimensional unitarity cuts as described in Section 3.
The approach we outlined is very powerful at one loop, but at higher loops becomes more difficult to use, because it requires two-loop integration. In particular, at higher loops simple decompositions of integrals along the lines of Eq. (2.13) do not exist. One might still construct the amplitudes using unitarity methods, and then extract their UV divergences by carrying out the loop integration, but one would like a simpler technique that avoids much of the technical complexity. Furthermore, to calculate two-loop divergences, one must also keep track of evanescent one-loop subdivergences, which contaminate the result. By an evanescent subdivergence we mean a subdivergence whose corresponding counterterm vanishes in strictly four dimensions, but which cannot be ignored in dimensional regularization (see e.g. Ref. [40, 41]). While not physical, these evanescent subdivergences greatly complicate higher-loop calculations, and it is better to use a method that avoids them, whenever possible. Ref. [16] gives a nontrivial two-loop example for Einstein gravity showing how on-shell methods can efficiently bypass evanescent effects [15] to determine renormalization-scale dependence.

2.3 Anomalous dimensions directly from unitarity cuts

A much more direct way to obtain anomalous dimensions is to focus on the renormalization-scale dependence encoded in the logarithms, and not on the divergences. The logarithms are detectable in four-dimensional unitarity cuts. Any dimensional imbalance in the kinematic arguments of the logarithms must be balanced by renormalization-scale dependence, so one can directly determine the renormalization-scale dependence and any anomalous dimensions by collecting the contributions from unitarity cuts. For example, this strategy has been used to greatly simplify the extraction of the two-loop renormalization-scale dependence in Einstein gravity [16].

The formalism of Caron-Huot and Wilhelm [12] gives a rather neat way to carry out this strategy, allowing us to extract the anomalous dimension at \( L \)-loops directly from phase-space integrals of lower-loop on-shell form factors and amplitudes. Among other useful features, this makes potential zeros in the anomalous dimension matrix much more transparent than with conventional methods [8].

By considering the analyticity of the form factors with respect to complex shifts in momenta, along with unitarity, Caron-Huot and Wilhelm derived the following compact equation:

\[
e^{-i\pi D} F_i^* = S F_i^*,
\]

which relates the phase of the S-matrix, \( S \), to the dilatation operator, \( D \) (ignoring trivial overall engineering dimensions). The dilatation operator acts on the conjugate form factor \( F_i^* \). Writing \( S = 1 + i\cal{M} \), Eq. (2.19) can be rewritten more practically as

\[
(e^{-i\pi D} - 1) F_i^* = i\cal{M} F_i^*,
\]

(2.20)
where the scattering amplitude, $\mathcal{M}$, acts as a matrix on the form-factor, yielding its imaginary part via the optical theorem$^4$. The right-hand side of this equation is defined to be a unitarity cut. As we discuss below, this equation precisely captures the notion that the scale dependence of $F_i$ is encoded in the coefficients of its logarithms. We note that the use of the complex conjugate form factor, $F^*$, only affects the imaginary part, which do not affect our calculations through two loops. Therefore, we drop the complex conjugation henceforth.

In dimensional regularization, the dilatation operator is related to the single renormalization scale, $\mu$, as
\[
D = -\mu \partial_\mu,
\]
reflecting the fact that $F_i$ can only depend on dimensionless ratios $s_{ij}/\mu$ (ignoring the overall engineering dimensions), and that logarithms in $s_{ij}$ kinematic variables must be balanced either by $\mu$ or by each other. The dilatation operator then acts on the form factors as
\[
DF_i = -\mu \partial_\mu F_i = [\Delta \gamma_{ij} + \delta_{ij} \beta] F_j,
\]
(2.21)
where we have used the renormalization-group equation (2.10). This, together with equation (2.19), gives us a powerful means to extract anomalous dimensions.

While Eqs. (2.19) and (2.21) are valid non-perturbatively, we can expand in perturbation theory to obtain order-by-order expressions for the anomalous dimensions. At one loop the expansion yields
\[
\left[ \Delta \gamma_{ij}^{(1)} + \delta_{ij} \beta^{(1)} \partial \right] F_j^{(0)} = -\frac{1}{\pi} (\mathcal{M}F_i)^{(1)},
\]
(2.22)
where the superscript denotes the order in perturbation theory. On the right-hand side $(\mathcal{M}F_i)^{(1)}$ indicates
\[
(\mathcal{M}F_i)^{(1)} = \sum_{k=2}^n \sum_c (\mathcal{M}_{k\rightarrow 2}^c)^{(0)} \otimes F_{n-k+2,i}^{(0)},
\]
(2.23)
$^4$In our notation the optical theorem states, $2\text{Im}F^*_i = \mathcal{M}F^*_i$ for form factors or $2\text{Im}\mathcal{M} = \mathcal{M}\mathcal{M}$ for amplitudes.
where the sums are over all kinematic channels and the $\otimes$ denotes a sum over intermediate two-particle states in the product. For a given kinematic channel this is given by the Lorentz-invariant phase-space integral

$$
(M F_i^{(1)})^{(2)} = \sum \int dLIPS_2 \sum h_1, h_2 A(1, \cdots, k, -\ell_1^{-h_1}, -\ell_2^{-h_2}) F_i^{(0)}(\ell_1^{h_1}, \ell_2^{h_2}, \cdots, n),
$$

where the sum over helicities also includes a sum over different states crossing the cut. In summary, $(MF_i^{(1)})^{(1)}$ corresponds to a sum over all one-loop two-particle unitarity cuts, as depicted schematically in Figure 1.

After rewriting the expression in terms of four-dimensional spinors, the two-particle phase-space integrals can be easily evaluated following the discussion of Ref. [12],

$$
\begin{pmatrix}
\lambda_1' \\
\lambda_2'
\end{pmatrix} = \begin{pmatrix}
\cos \theta & -\sin \theta e^{i\phi} \\
\sin \theta & \cos \theta
\end{pmatrix} \begin{pmatrix}
\lambda_1 \\
\lambda_2
\end{pmatrix},
$$

where the $\lambda_i$ and $\bar{\lambda}_i = \lambda_i^*$ spinors depend on the momenta of the external legs and the $\lambda_i'$ and $\bar{\lambda}_i' = \lambda_i'^*$ spinors on the momenta of the cut legs. With this parametrization the integration measure is simply,

$$
\int dLIPS_2 \equiv \frac{1}{16\pi} \int_0^{2\pi} \frac{d\phi}{2\pi} \int_0^\pi 2\cos \theta \sin \theta d\theta.
$$

In the definition of the phase-space measure, here we have included an additional symmetry factor of 1/2, relative to the usual volume of two-particle phase space, i.e., $8\pi$. This is generally convenient but requires some care when non-identical particles cross the cut, where we will need to multiply by two to cancel the symmetry factor.

Next consider two loops. Expanding Eq. (2.20) through this order, we obtain

$$
\begin{align*}
\left[\Delta \gamma_{ij}^{(1)} + \delta_{ij} \beta^{(1)} \right] F_j^{(1)} + \left[\Delta \gamma_{ij}^{(2)} + \delta_{ij} \beta^{(2)} \right] F_j^{(0)} \\
- i\pi \frac{1}{2} \left[\Delta \gamma_{ik}^{(1)} + \delta_{ik} \beta^{(1)} \right] \left[\Delta \gamma_{kj}^{(1)} + \delta_{kj} \beta^{(1)} \right] F_j^{(0)} = -\frac{1}{\pi} (MF_i^{(2)}).
\end{align*}
$$

Figure 2. Unitarity cuts relevant for the extraction of anomalous dimensions from two-loop form factors, using the same notation as in Figure 1. The darker blobs indicate a higher-dimension operator insertion. The blobs with a hole indicate a one-loop form factor or amplitude.
On the right-hand side of this equation, \((\mathcal{M}F_i)^{(2)}\) denotes collectively the three two-loop unitarity cuts displayed in Figure 2,

\[
(\mathcal{M}F_i)^{(2)} = \sum_{k=2}^{n} \sum_{c} \left[ (\mathcal{M}^{(k-2)}_c) \otimes F^{(0)}_{n-k+2,i} + (\mathcal{M}^{(k-2)}_c)^{(0)} \otimes F^{(1)}_{n-k+2,i} + (\mathcal{M}^{(k-2)}_c)^{(0)} \otimes F^{(0)}_{n-k+3,i} \right].
\] (2.28)

In the first term we find two-particle cuts composed of the one-loop amplitude and the tree-level higher-dimension form factor depicted in Figure 2(a). These are

\[
(\mathcal{M}^{(k-2)}_c) \otimes F^{(0)}_{n-k+2,i} = \int dLIPS_2 \sum_{h_1,h_2} (1 \cdots k) [M|\ell_{1}^{h_1} \ell_{2}^{h_2})^{(1)} \langle \ell_{1}^{h_1} \ell_{2}^{h_2} \cdots n|O_i|0)\rangle
= \int dLIPS_2 \sum_{h_1,h_2} A^{(1)}(1, \cdots, k, -\ell_{1}^{-h_1}, -\ell_{2}^{-h_2}) F^{(0)}_{1}(\ell_{1}^{h_1}, \ell_{2}^{h_2}, \cdots, n). \] (2.29)

Similarly, the second term, shown in Figure 2(b), is a combination of cuts composed by the tree-level amplitude and the one-loop higher-dimension operator, which are

\[
(\mathcal{M}^{(k-2)}_c)^{(0)} \otimes F^{(1)}_{n-k+2,i} = \int dLIPS_2 \sum_{h_1,h_2} (1 \cdots k) [M|\ell_{1}^{h_1} \ell_{2}^{h_2})^{(1)} \langle \ell_{1}^{h_1} \ell_{2}^{h_2} \cdots n|O_i|0)\rangle
= \int dLIPS_2 \sum_{h_1,h_2} A^{(0)}(1, \cdots, k, -\ell_{1}^{-h_1}, -\ell_{2}^{-h_2}) F^{(1)}_{1}(\ell_{1}^{h_1}, \ell_{2}^{h_2}, \cdots, n). \] (2.30)

Finally, the third term is composed of three-particle cuts involving two tree-level objects, as in Figure 2(c)

\[
(\mathcal{M}^{(k-2)}_c)^{(0)} \otimes F^{(1)}_{n-k+3,i} = \int dLIPS_3 \sum_{h_1,h_2,h_3} (1 \cdots k) [M|\ell_{1}^{h_1} \ell_{2}^{h_2} \ell_{3}^{h_3})^{(0)} \langle \ell_{1}^{h_1} \ell_{2}^{h_2} \ell_{3}^{h_3} \cdots n|O_i|0)\rangle
= \int dLIPS_3 \sum_{h_1,h_2,h_3} A^{(0)}(1, \cdots, k, -\ell_{1}^{-h_1}, -\ell_{2}^{-h_2}, -\ell_{3}^{-h_3}) F^{(0)}_{1}(\ell_{1}^{h_1}, \ell_{2}^{h_2}, \ell_{3}^{h_3}, \cdots, n). \] (2.31)

A parameterization analogous to (2.25) for the three-particle cut is given in Ref. [12]. We will not evaluate any three-particle cuts in the present work, so we refer the reader to this work for more details.

We can rearrange Eq. (2.27) to put it into a more convenient form for extracting two-loop anomalous dimensions. First, note that the imaginary part of Eq. (2.27)

\[
-\frac{i}{2} \left[ \Delta \gamma_{ik}^{(1)} + \delta_{ik}^{(1)} \partial \right] [\Delta \gamma_{kj}^{(1)} + \delta_{kj}^{(1)} \partial] F_{j}^{(0)} = -\frac{1}{2} \text{Im}(\mathcal{M}F_i)^{(2)},
\] (2.32)

does not feature the two-loop anomalous dimensions. Using the optical theorem again, we write its right-hand side in terms of unitarity cuts

\[
\text{Im}(\mathcal{M}F_i)^{(2)} = (\mathcal{M}\mathcal{M}F_i)^{(2)},
\] (2.33)
where the relevant cuts are the iterated two-particle cuts in Fig. 3. For instance \((\mathcal{M} \mathcal{M} F_i)^{(2)}\) contains terms of the form
\[
\int d\text{LIPS}_2 d\text{LIPS}_2' \sum_{h_1, h_2} \sum_{h_1', h_2'} \langle \cdots | \ell_1^{h_1} \ell_2^{h_2} |^0 \rangle \langle \ell_1^{h_1'} \ell_2^{h_2'} |^0 \rangle \langle \ell_1' \ell_2' | \mathcal{O}_i |^0 \rangle ,
\]
which correspond to cuts of the type in Fig. 3(a). Note that Eq. (2.33) does not include a factor of 1/2 from the optical theorem because the imaginary part can arise from cutting either the one-loop amplitude or form factor, which give identical contributions.

Eq. (2.32) does not contain the two-loop anomalous dimensions but instead captures the exponentiation of one-loop anomalous dimensions and the associated logarithms. Nonetheless (2.33) can be used to simplify the real part of Eq. (2.27), which yields
\[
\left[ \Delta \gamma^{(1)}_{ij} + \delta_{ij} \beta^{(1)} \partial \right] \text{Re} F_{j}^{(1)} + \left[ \Delta \gamma^{(2)}_{ij} + \delta_{ij} \beta^{(2)} \partial \right] F_{j}^{(0)} = -\frac{1}{\pi} \text{Re} (\mathcal{M} F_i)^{(2)} = -\frac{1}{\pi} (\mathcal{M} F_i - \mathcal{M} \mathcal{M} F_i)^{(2)} .
\]
Note that the right-hand side can be rewritten using
\[
(\mathcal{M} F_i - \mathcal{M} \mathcal{M} F_i)^{(2)} = \left[ \left( \mathcal{M} - \frac{1}{2} \mathcal{M} \mathcal{M} \right) \left( F_i - \frac{1}{2} \mathcal{M} F_i \right) \right]^{(2)} = \left[ \text{Re}(\mathcal{M}) \text{Re}(F_i) \right]^{(2)} ,
\]
and with this we arrive at
\[
\left[ \Delta \gamma^{(1)}_{ij} + \delta_{ij} \beta^{(1)} \partial \right] \text{Re} F_{j}^{(1)} + \left[ \Delta \gamma^{(2)}_{ij} + \delta_{ij} \beta^{(2)} \partial \right] F_{j}^{(0)} = -\frac{1}{\pi} \left[ \text{Re}(\mathcal{M}) \text{Re}(F_i) \right]^{(2)} .
\]
We use this equation to extract two-loop anomalous dimensions. In practice Eq. (2.37) simply instructs us to drop the imaginary parts of the one-loop matrix elements when calculating the cuts in Figs. 2(a) and 2(b). On the left-hand side, we now see the appearance of one-loop anomalous dimensions and the \(\beta\)-function, as well as the one-loop form factor \(F_i^{(1)}\). The two-loop UV anomalous dimension \(\gamma^{UV(2)}_{ij}\) contained in \(\Delta \gamma^{(2)}_{ij}\) is the object of interest, but to extract it we first need to remove \(\gamma^{IR(2)}_{ij}\), which requires an understanding of the IR singularities, which we discuss below.

### 2.3.1 Simplifying strategies

A strategy that greatly simplifies the analysis is to choose an external state with the minimal number of external legs that is sensitive to the operator of interest, i.e. select the operator’s minimal form factor. In this way we can avoid terms of the form \(\beta^{(n)} \partial F_i^{(0)}\) in Eqs. (2.27) and (2.37), since, under this choice, \(F_i^{(0)}\) is local, and thus does not
depend on the dimension-four couplings, $g^{(4)}$. This strategy was used in Ref. [8] to prove nonrenormalization theorems at the first loop order where diagrams exist.

More generally, the $\beta$-function can no longer be eliminated by using minimal form factors whenever the one-loop form factor with an $O_i$ insertion, $F^{(1)}_i$, produces a nonzero result with the chosen external states. In addition, the $\beta$-function acting on the one-loop anomalous-dimension matrix is nonzero if the matrix elements themselves are nonzero. For example, to determine the renormalization of $O_{F^3}$ by itself at two loops, we would evaluate Eq. (2.37) with the external state $\langle 1^+2^+3^+ \rangle$. In this case the term $\beta^{(2)} \partial F^{(0)}_{F^3}$ would vanish, though the term $\beta^{(1)} \partial F^{(1)}_{F^3}$ would remain.

Unlike the $\beta$-function, the IR anomalous dimensions are non-trivial to eliminate. Ref. [12] removes them by subtracting, at the integrand level, form factors of global symmetry currents, such as the stress-tensor, which are UV finite but contain the same IR divergences. Alternatively, one can use the same on-shell methods to calculate them and subtract them after integration. At one loop, the structure of infrared divergences is well understood [42–44], and it is straightforward to subtract them after integration. We explain how to carry this out at the level of the amplitudes in the next section. Furthermore, whenever we are interested in a leading off-diagonal element of the anomalous dimension matrix, the IR anomalous dimensions does not appear, since the infrared divergences are diagonal in the operators (excluding color).

Finally, form factors are useful for operators with only two or three external fields, since they allow nonzero results when kinematics would otherwise set amplitudes with fewer than four external particles to zero. Here we generally set the operator momentum insertion $q = 0$ and work in terms of amplitudes whenever possible, i.e. whenever there are four or more external states.

2.4 Comments on evanescent operators

When extracting anomalous dimensions from UV divergences in dimensional regularization one must carefully keep track of evanescent operators [40, 41]. These operators are non-trivial in $D$-dimensions, but whose matrix elements vanish for any choice of external four-dimensional states. In the context of the SMEFT an example of an evanescent
operator would be the Lorentz–Fierz identities

\[
\mathcal{O}_{\text{Fierz,L}} = (\bar{\psi}_L^m \gamma^\mu \psi_L^n)(\bar{\psi}_L^p \gamma_\mu \psi_L^r) + (\bar{\psi}_L^p \gamma^\mu \psi_L^r)(\bar{\psi}_L^m \gamma_\mu \psi_L^n),
\]

\[
\mathcal{O}_{\text{Fierz,R}} = (\bar{\psi}_R^m \gamma^\mu \psi_R^n)(\bar{\psi}_R^p \gamma_\mu \psi_R^r) + (\bar{\psi}_R^p \gamma^\mu \psi_R^r)(\bar{\psi}_R^m \gamma_\mu \psi_R^n),
\]

where we raised the flavor indices for convenience) which are identically zero in four but not in arbitrary dimensions. More generally one can easily construct such operators by antisymmetrizing over five or more Lorentz indices. In the context of our model, an example of such an evanescent operator is

\[
(\bar{\psi} \gamma_{[\alpha} \gamma^\mu \gamma^\nu \gamma^\rho \gamma_{\beta]} \psi)(\bar{\psi} \gamma_{[\alpha} \gamma^\mu \gamma^\nu \gamma^\rho \gamma_{\beta]} \psi).
\]

One-loop diagrams might contain a $1/\epsilon$ divergence proportional to the matrix element of an evanescent operator. While this does not affect one-loop anomalous dimensions because we can take the external states to be four-dimensional, when inserted in a higher-loop diagram in the context of dimensional regularization such evanescent operators are activated and can generate both UV divergent and finite contributions. In fact, they are needed to properly subtract subdivergences. These effects must be taken into account in order to correctly extract two-loop UV divergences and their associated anomalous dimension. In practice we can deal with the effects of evanescent operators [40, 41], but the number of them grows with dimension and loop order (especially in the presence of fermions). For this reason it would be desirable to avoid them when possible, since they are a technical complication due to the use of dimensional regularization, and ultimately we would expect that they do not affect the physics [15].

We expect the on-shell methods presented above to completely sidestep the issue of evanescent operators when obtaining anomalous dimension, at least through two loops. Ref. [16] provides a nontrivial demonstration that complications from evanescent operators can be completely sidestepped using on-shell methods and by focusing on renormalization-scale dependence instead of divergences. In the two-loop formulas used here, anomalous dimensions and associated logarithms are given directly in terms of four-dimensional unitarity cuts of tree and one-loop objects. This automatically eliminates most of the evanescent dependence, except for finite shifts in one-loop matrix elements with evanescent operator insertions. We expect that any remaining evanescent dependence in the one-loop amplitudes or form factors to be eliminated by finite renormalizations [41]. Given the usual subtleties of dealing with evanescent operators, it would, of course, be important to explicitly verify that including or not including evanescent operators in the one- and two-loop anomalous dimension matrix amounts to a scheme choice.

2.5 Anomalous dimensions and non-interference

As noted in Ref. [45] helicity selection rules imply the non-interference of SMEFT tree-level matrix elements when constructing cross sections. This has important con-
sequences in the context of the SMEFT, where the possibility of measuring the coefficient of higher-dimension operators at colliders can be impacted by the vanishings in the interference of the Standard-Model tree amplitudes and those of higher-dimension operators, when computing cross sections. A connection between one-loop anomalous dimension and interference terms can be seen in Eq. (2.22), where, upon setting $q = 0$, the form factors become amplitudes and the right-hand side directly captures the interference of tree-level dimension-four and dimension-six amplitudes. Note that this holds even when the anomalous dimension is not zero, in which case this equation relates the interference terms to simpler objects, namely the one-loop anomalous dimensions and tree-level matrix elements. Of course, in a realistic cross-section calculation one would not integrate over the full phase space, due to experimental cuts.

At two loops the connection between zeros in the anomalous dimensions and non-interference is not as direct, since it requires cancellations between both sides of Eq. (2.27). Eq. (2.32) shows that, in general, the imaginary part of the interference term is given by the square of one-loop anomalous dimensions times tree-level matrix elements. Instead of non-interference, Eq. (2.35) shows that a vanishing two-loop anomalous dimension would imply that the real part of interference term is simply related to the product of one-loop anomalous dimensions and one-loop matrix elements. It would be interesting to further investigate the consequences stemming from these observations, even in the presence of experimental cuts.

3 One-loop amplitudes and anomalous dimensions

In this section we describe our generalized unitarity calculation of the one-loop amplitudes with an insertion of a higher-dimensional operator in our simplified model. We then extract the one-loop anomalous dimension matrix of this theory. Finally, we comment on the structure of rational terms in the amplitudes and on the ability to set some of them to zero with a judicious scheme choice. The results in this section are building blocks needed for the two-loop analysis in the next section. In addition, they provide one-loop anomalous dimensions that can be cross-checked against those in Refs. [4].

3.1 One-loop amplitudes from generalized unitarity

The generalized unitarity method [11, 29, 30] for constructing one-loop amplitudes can be found in various reviews, for example see Ref. [46], but here we briefly review the procedure for the one-loop case. To construct the full one-loop amplitudes to all orders in the dimensional-regularization parameter $\epsilon$, we begin with the $D$-dimensional four-point tree-level amplitudes with or without insertions of the dimension-6 operators (given in Appendix B). By using $D$-dimensional tree amplitudes, we ensure that the cuts
appropriately capture the coefficients of the $D$-dimensional box, triangle, and bubble scalar integrals that form a basis for the full one-loop amplitudes, as in Eq. (2.13). In general, the coefficients have $\epsilon$ dependence, and expanding in $\epsilon$ produces rational terms that would not automatically be included if a purely four-dimensional approach to the cuts were used [11]. Besides $\epsilon$, the coefficients only depend on the Mandelstam invariants $s = (k_1 + k_2)^2$, $t = (k_2 + k_3)^2$ and $u = (k_1 + k_3)^2$.

We construct the cuts in the standard way. For example, the integrand-level $s$-channel cut with an $O_n$ operator insertion is given by

$$\sum_i C^{[i]} \left( [a_{4,n,i}^{st} I_{4,st} + a_{4,n,i}^{su} I_{4,su} + a_{3,n,i}^{s} I_{3,s} + a_{2,n,i}^{s} I_{2,s}] \right) \bigg|_{\ell^2 = 0}$$

$$= \sum_{\text{states}} \sum_j C^{[j]} A_n^{(0)}(1, 2, \ell_1^{h_1}, \ell_2^{h_2}) \sum_k C^{[k]} A^{(0)}(0, -\ell_2^{h_2}, -\ell_1^{h_1}, 3, 4)$$

$$+ \sum_{\text{states}} \sum_j C^{[j]} A_n^{(0)}(1, 2, \ell_1^{h_1}, \ell_2^{h_2}) \sum_k C^{[k]} A_n^{(0)}(0, -\ell_2^{h_2}, -\ell_1^{h_1}, 3, 4),$$

where the sum over states includes the helicity and the color, and, for this case, $\ell_2 = -(\ell_1 + k_1 + k_2)$. The $C^{[i]}$ are the appropriate color factors for the associated amplitudes. Since the cut legs are on-shell, where $\ell_1^2 = \ell_2^2 = 0$. Often, the external particles will restrict $A_n^{(0)}$ to be nonzero only for certain cuts or placements within the cuts, depending on the field content of the operator inserted.

As an example, the cuts of the amplitude $A_{F_3}^{(1)}(1, 2, 3, 4)$, are shown in Figure 4, where the operator $O_{F_3}$ should be inserted on either side of the cuts, when the tree amplitudes exist. Other amplitudes with four-point operators require only the cuts corresponding to their correct external particles. The color factors $C^{[j]} C^{[k]}$ can be reduced to the appropriate color basis of the full amplitude, $C^{[i]}$, based on the external particles. Doing so determines the contribution from each color-decomposed cut.

We evaluate the cuts using the $D$-dimensional state sum completeness relations,

$$\epsilon_i^{\mu} \odot \epsilon_i^{\nu} = \sum_{\text{states}} \sum_{h} \epsilon_i^{(h)\mu} \epsilon_i^{(h)\nu} = -g^{\mu\nu} + \frac{q^\mu k_i^\nu + k_i^\mu q^\nu}{q \cdot k_i},$$

$$\overline{u}_i \odot u_i = \sum_{\text{states}} \sum_{h} \overline{u}_i^{(h)} u_i^{(h)} = \mathbf{k}_i,$$

where $q$ is an arbitrary reference vector with $q^2 = 0$.

The next task is to merge the cuts and to integrate. One can merge the cuts at the level of the integrand to find a single integrand that has the correct cuts in all channels. However, is it is generally simpler to merge the integrated results from each cut, treating each cut as an off-shell object, but dropping contributions that do not have a cut in the given channel. Integration is done by projecting each cut for a given process onto a basis of gauge-invariant tensors, as described in more detail in
Figure 4. The necessary cut for constructing a two-fermion, two-vector amplitude. For an amplitude with an insertion of a higher-dimension operator, one should insert the operator into either side of the diagrams when possible. The wavy lines are vector bosons, the lines with arrows fermions and the dashed lines scalars.

Appendix A. Although the methods we use to extract anomalous dimensions do not require us to keep track of evanescent divergences, because the projection technique is fully $D$ dimensional, we track them and confirm that they do not enter our calculations of various entries in the two-loop anomalous-dimension matrix. An alternative is to use spinor-helicity methods [47] which are much more powerful when the number of external legs increases. These have been successfully used for both chiral [29] and higher-loop calculations [48], but then additional care is needed to deal with subtleties that arise from using dimensional regularization.

After projection, the cut integrand is rewritten in terms of inverse propagators. We reduce the remaining integrals to the basis of scalar integrals in Eq. (2.13) using integration by parts relations as implemented in FIRE [33]. Cut merging is then straightforward, as the coefficients of integrals in the merged amplitude can be read directly off the results from each cut, summed over the possible particles crossing the cut. For example, the $s$-channel cut in Eq. (3.1) yields the coefficients of the $s$-channel bubble and triangle, as well as those of the $(s, t)$ and $(s, u)$ boxes in Eq. (2.13).

The full set of $D$-dimensional four-point one-loop amplitudes for the dimension-six operators in our model are given in the ancillary file [34]. These expressions are valid to all orders in $\epsilon$, but to obtain the finite, renormalized expressions needed to feed into our calculation of two-loop anomalous dimensions, we need to subtract the UV poles.

The one-loop amplitudes are IR divergent. The IR singularities of gauge theories
are well understood [39, 42–44], and can be expressed in terms of lower-loop amplitudes involving the same operator insertion and external particles. The explicit form of the one-loop infrared singularity, for example, is given by

$$A_i^{(1)} = I^{(1)} A_i^{(0)},$$  \hspace{1cm} (3.3)$$

where the IR operator $I^{(1)}$ is given by [39, 42, 43]

$$I^{(1)} = \frac{e^{\epsilon \gamma_E}}{\Gamma(1-\epsilon)} \sum_{p=1}^{n} \sum_{q \neq p} \frac{T_p \cdot T_q}{2} \left[ \frac{\gamma_{\text{IR}}^{(1)}(\epsilon)}{\epsilon^2} - \frac{\gamma_{\text{IR}}^{(1)}(\epsilon)}{\epsilon^2} \right] \left( -\frac{\mu^2}{2k_p \cdot k_q} \right)^\epsilon,$$  \hspace{1cm} (3.4)$$

where the sums are over external particles. The color charge $T_p = \{ T_a^p \}$ is a vector with respect to the generator label $a$ and a SU($N$) matrix with respect to the outgoing particle $p$. The infrared divergence includes a $1/\epsilon^2$ pole, with coefficient given by the cusp anomalous dimension $\gamma_{\text{cusp}}^{\text{IR}}(1) = 4 \tilde{g}^2$, and $1/\epsilon$ poles, with coefficient given by the collinear anomalous dimension of particle $p$ given in Eq. (2.16). By obtaining the IR dependence of the one-loop amplitudes from Eq. (3.3), we can subtract it from the full one-loop amplitudes. As always, the definition of the IR-divergent parts carries with it some arbitrariness as to which finite pieces are included.

The remaining poles in $\epsilon$ are UV poles, which we then match to the appropriate tree-level counterterm amplitude containing an insertion of the operator $O_j$. A complication is that there can be multiple operators corresponding to the same external particle content, but with different color structures. Therefore, in these cases the coefficient of a single color factor in the loop amplitude is insufficient for the purpose of determining the anomalous dimensions, and in principle all the color factors for the given process and operator insertion must be considered simultaneously. For example, the one-loop amplitude with an insertion of the $O_{(D^2 \varphi^2 \bar{\psi}^2)^2}$ operator and four external scalars determines the renormalization of both the $O_{(D^2 \varphi^4)^1}$ and the $O_{(D^2 \varphi^4)^2}$ operators, where the operators are given in Table 1.

In some cases the IR structure is trivial, e.g. when the IR anomalous dimensions are zero simply because there are no lower-loop amplitudes for a given operator and given external state. Our examples in Section 4 follow this pattern. For instance, in the example of $O_{(D^2 \varphi^4)^1}$, renormalizing $O_{(\varphi^4)^1}$ at two loops, there is no tree level or one-loop amplitude with an insertion of $O_{(D^2 \varphi^4)^1}$, which has an external state of four fermions, simply due to the lack of Feynman diagrams. Since the full IR dependence is proportional to lower-loop amplitudes, this implies there cannot be an IR divergence at two loops. This same reasoning underpinned the non-renormalization theorem in Ref. [8]. More generally, one needs to account for the infrared singularities.

---

5The difference with the formulas in those references is due to our normalization of the SU($N$) generators.

6In physical quantities this arbitrariness cancels between real emission and virtual contributions.
3.2 One-loop UV anomalous dimensions

After subtracting the IR singularities, the only remaining $1/\epsilon$ poles in the amplitudes correspond to the desired one-loop anomalous dimensions,

\[
\begin{align*}
\dot{c}_{F^3} &= \tilde{g}^2(12N - 3b_0)c_{F^3}, \\
\dot{c}_{(\varphi^2F^2)_1} &= \tilde{g}^2\left(-5c_{F^3} - \frac{(3N^2 - 7) + 2Nb_0}{N}c_{(\varphi^2F^2)_1} + \frac{N^2 - 4}{N^2}c_{(\varphi^2F^2)_2}\right) + \tilde{\lambda} 4(1 + N)c_{(\varphi^2F^2)_1}, \\
\dot{c}_{(\varphi^2F^2)_2} &= \tilde{g}^2\left(-Nc_{F^3} + 2c_{(\varphi^2F^2)_1} + \frac{2N^2 - 5 - 2Nb_0}{N}c_{(\varphi^2F^2)_2}\right) + \tilde{\lambda} 4c_{(\varphi^2F^2)_2}, \\
\dot{c}_{(D^2\varphi^4)_1} &= \tilde{g}^2\left(\frac{3(N + 1)}{N}c_{(D^2\varphi^4)_1} + \frac{2(N - 2)(N_s + 9)}{3N}c_{(D^2\varphi^4)_2} + \frac{4N - 2}{3N}c_{(D\varphi^2\psi^2)_2}\right) + \lambda 12c_{(D^2\varphi^4)_1}, \\
\dot{c}_{(D^2\varphi^4)_2} &= \tilde{g}^2\left(\frac{36NC_F - 2(N - 1)(N_s + 9)}{3N}c_{(D^2\varphi^4)_2} + \frac{3(N - 2)(N + 1)}{2N}c_{(D^2\varphi^4)_1} \\
&+ \frac{2(N - 1)}{3N}c_{(D\varphi^2\psi^2)_2}\right) + \tilde{\lambda} \left(2(N - 2)c_{(D^2\varphi^4)_1} + 8(N + 1)c_{(D^2\varphi^4)_2}\right), \\
c^{-pr}_{(D\varphi^2\psi^2)_1} &= 0, \\
c^{-pr}_{(D\varphi^2\psi^2)_2} &= \tilde{g}^2\left(\frac{1}{3}N_s c_{(D^2\varphi^4)_2} \delta^{-pr} + \frac{1}{3}(-9N + N_s)c^{-pr}_{(D\varphi^2\psi^2)_2} + \frac{4}{3}N_f c_{(D\varphi^2\psi^2)_2} \delta^{-pr} \\
&- \frac{2}{3}N_f c^{pr}_{D\varphi^2\psi^2} - \frac{2}{3}N_f \left(2c^{pr}_{D\varphi^2\psi^2} - \frac{1}{N}c^{pr}_{D\varphi^2\psi^2}\right)\right), \\
c^{-mnpr}_{(\varphi^4)_1} &= \tilde{g}^2\left(\frac{6(N^2 - 1)}{N^2}c^{-mnpr}_{(\varphi^4)_2}\right), \\
c^{-mnpr}_{(\varphi^4)_2} &= \tilde{g}^2\left(-\frac{N_s}{3}c^{-mnpr}_{(D\varphi^2\psi^2)_2} \delta^{-pr} + c^{-pr}_{(D\varphi^2\psi^2)_2} \delta^{-mn} \\
&+ \frac{2}{3}N_f \left(\delta^{-mn}c^{pr}_{D\varphi^2\psi^2} + \delta^{-pr}c^{mn}_{D\varphi^2\psi^2}\right) + \frac{6}{N}c^{-mnpr}_{(\varphi^4)_2} \\
&+ \frac{2N_f}{3N} \left(2N(\delta^{-pr}c^{mn}_{(\varphi^4)_2} + \delta^{-pr}c^{mn}_{(\varphi^4)_2}) - (\delta^{-pr}c^{mn}_{(\varphi^4)_2} + \delta^{-pr}c^{mn}_{(\varphi^4)_2})\right)\right). \tag{3.5}
\end{align*}
\]

Here $N_s$ is left as a parameter to track contributions from scalar loops. In our model it should be set to unity. These anomalous dimensions have been extracted directly from the scattering amplitudes, and, as a cross-check, we also used the unitarity cut method explained in the previous section [12] for computing directly the anomalous dimensions. The structure of the anomalous dimension matrix is summarized in Table 2. It is worth pointing out the simplicity in the renormalization and mixing of $(D\varphi^2\psi^2)_1$ and $(\varphi^4)_1$, which is due to these operators being a product of global symmetry currents, which
Table 2. Structure of the zeros in the one-loop anomalous dimension matrix. The ∅ entries indicate there are no contributing one-loop diagrams, whereas a 0 alone indicates that there are one-loop diagrams that could contribute, but actually give a vanishing result. The operators labeling the rows are renormalized by the operators labeling the columns.

| **(\psi^4)_2** | 0         | ∅              | ∅              | ∅              | ∅              | ∅              | 0              | 0              | 0              |

heavily constrains the kind of states they can overlap with. This is special in our model, which does not contain an Abelian gauge field. In the presence of the latter, the operators would be a product of gauge symmetry currents (just like \( (D \varphi^2 \psi^2)_2 \) and \( (\psi^4)_2 \)) which are renormalized [49], so the anomalous dimension matrix will receive contributions proportional to the Abelian gauge coupling.

We use these results to verify a representative set of the one-loop anomalous dimension calculated in Ref. [4], including entries from nearly all classes of operators. Additional details about this verification is given in Section 5. This provides a non-trivial check on our one-loop results, which we then feed into the two-loop anomalous dimension calculations.

### 3.3 Structure of one-loop amplitudes and rational terms

After subtracting the infrared singularities and renormalization, the amplitudes are finite. The full set of results for our renormalized and IR-subtracted amplitudes is given in Appendix B. The renormalized helicity amplitudes include a large number of zeros, including those which would otherwise be rational contributions. A number of these zeros were pointed out in Ref. [10], and explained using angular-momentum selection rules in Ref. [9]. These selection rules explain most, but not all, of the observed zeros, leaving some “accidental” zeros, displayed as a blue 0 in Table 3. These zeros can
be considered an accident of the simplicity of our model. In each case, the entry directly below the blue zero shows that while the accident holds for that particular operator, another operator with identical particle content, but different color structure, produces a nonzero result in \( \overline{\text{MS}} \). The reason for this is that only the first of each pair of operators is a product of global symmetry currents in our model (c.f. our discussion in Section 3.2). In a more general theory with an Abelian gauge field, one would expect

Table 3. Structure of the zeros, rational terms, and logarithms in the full one-loop helicity amplitudes. In this table each entry indicates whether the operator of its row produces the amplitude with external state corresponding to its column. \( V \) denotes a vector boson, \( \psi \) a fermion and \( \varphi \) a scalar.
that such zeros would not occur.

More interesting is the surprisingly large number of amplitudes—with shaded (red) rectangles around 0 entries in Table 3—which do not evaluate to zero in the standard $\overline{\text{MS}}$ renormalization scheme, but which are proportional to a linear combination of the tree-level amplitudes of the dimension-six operators. These amplitudes can therefore be set to zero by an appropriate choice of finite counterterms. This corresponds to a scheme change, showing that these amplitudes are scheme dependent. Explicit examples of how these rational shifts are related to the scheme dependence of the two-loop anomalous dimensions is discussed at length in the next section.

Similarly, for a number of amplitudes (marked $L_0$ and in a shaded red rectangle in Table 3), all rational terms in the amplitude can be removed with an appropriate choice of finite counterterms, leaving behind logarithmic terms which cannot be subtracted in this way. These logarithmic terms do not appear to be of the right form to produce local results, so we may expect that they also do not produce contributions to the two-loop anomalous dimensions via Eq. (2.37). It would be interesting to investigate this, but we refrain from doing so here. Remarkably, only a small number of the one-loop amplitudes contain rational terms that cannot be removed via finite counterterms.

As expected, however, some amplitudes do contain non-local rational amplitudes, prohibiting such a simple subtraction by a local counterterm. It is interesting to note that all the nonzero rational amplitudes of $(D^2 \varphi^4)_2, (D_\varphi^2 \psi^2)_2, (\psi^4)_1$ and $(\psi^4)_2$ are non-local but can be individually set to zero by the introduction of an $F^3$ finite counterterm. This procedure, however, will always introduce new diagrams which make other $\emptyset$ entries in the same row nonzero. For example, since the $F^3$ tree contains nonzero four-vector tree amplitudes, entries in these columns will no longer be zero. Another interesting observation is that the UV divergence in the only nonzero amplitude of $(D_\varphi^2 \psi^2)_1$ cancels between terms, but the logarithms remain.

The vanishing one-loop amplitudes strongly suggests that many contributions to the two-loop anomalous dimension matrix should vanish, beyond those identified in Ref. [8]. For many of the two-loop anomalous dimensions, these zeros imply that the only contribution to the final result comes from the three-particle cut, making their evaluation much simpler than expected, since only four-dimensional tree-level objects are involved. In a number of cases, including multiple examples in Section 4, the three-particle cut also vanishes, thereby immediately implying that the corresponding two-loop anomalous dimension is zero. Of course, the amplitudes corresponding to the entries of Table 3 with shaded (red) rectangles are not zero when working strictly in $\overline{\text{MS}}$, so one would need to evaluate the two-particle cuts in order to determine the corresponding anomalous dimensions in this scheme.

Finally, the appearance of many zeros in Table 3 suggests that even more zeros in the two-loop anomalous dimension might be found by using the helicity selection
rules of Ref. [7] or the angular momentum conservation rules of Ref. [9], given that the remaining three-particle cut only involves four-dimensional tree amplitudes, which are often restricted by these selection rules.

4 Two-loop zeros in the anomalous dimension matrix

In this section we use the results of the previous section and the tools in Section 2.3 to obtain two-loop anomalous dimensions in our simplified theory. These calculations will unveil a number of mechanisms that give rise to a wealth of new zeros in the two-loop anomalous dimension matrix. As mentioned in the previous section, two-loop anomalous dimensions are scheme dependent. This makes the question of whether a two-loop anomalous dimension is zero somewhat ill-defined. We will show explicit examples of anomalous dimensions that are nonzero in the \( \overline{\text{MS}} \) scheme, but for which we can find a scheme in which they are zero. In addition, we demonstrate the cancellation of logarithms in the evaluation of Eq. (2.37) when they appear. For simplicity, throughout this section, we assume the case of a single flavor of fermion, drop the flavor indices, and set \( N_f = N_s = 1 \). In all the cases we consider here, the one-loop amplitudes required for the two-loop computation are infrared finite, simplifying the discussion.

4.1 Zeros from length selection rules

First we summarize the results of our previous paper, which points out a set of nontrivial zeros in the two-loop anomalous dimension matrix of generic EFTs [8]: operators with longer length—those with more field insertions—are often restricted from renormalizing operators with shorter length, even if Feynman diagrams exist. Specifically, for operators \( \mathcal{O}_l \) and \( \mathcal{O}_s \), with lengths \( l(\mathcal{O}_l) \) and \( l(\mathcal{O}_s) \), \( \mathcal{O}_l \) can renormalize \( \mathcal{O}_s \) at \( L \) loops only if the inequality \( L > l(\mathcal{O}_l) - l(\mathcal{O}_s) \) is satisfied. This implies, for example, that the operator \( \mathcal{O}_{\phi^6} \) cannot renormalize any of the other operators in our model (Table 1) at two loops. This is due to the fact that any two-loop diagram with an insertion of \( \mathcal{O}_{\phi^6} \) and four external particles must contain a scaleless integral, which evaluates to zero in dimensional regularization. This implies that the anomalous dimensions vanish, if there are no IR divergences. In this case the lack of infrared singularities follows from the fact that they are proportional to the corresponding lower-loop amplitudes, which vanish due to the lack of diagrams when the bound is not satisfied.

In addition, as shown in Ref. [8], in a theory with multiple types of fields, such as the SMEFT, additional vanishing can occur at loop orders higher than indicated by the above bound. In general, whenever the only diagrams one can draw with an insertion of \( \mathcal{O}_l \) and the external particles of \( \mathcal{O}_s \) always involve scaleless integrals, then there will be no renormalization of \( \mathcal{O}_s \) by \( \mathcal{O}_l \). In the language of Section 2.3, this happens because

\footnote{This is in contrast to the \( \beta \)-function, which is scheme dependent starting at three loops [35, 50].}
there are no nonzero cuts on the right-hand side of Eq. (2.37) or the higher loop analog. Iteration pieces on the left-hand-side of Eq. (2.37)—terms other than $\gamma_{(L)_{\text{right}}}^{F_0^{(0)}}$—are also set to zero by the presence of scaleless integrals. Examples of this form of the rule in effect include the lack of two-loop renormalization of $O_{F_3}$ by $O_{D_2 \varphi^2}$, $O_{D_2 \varphi^4}$, or $O_{\varphi^4}$.

Another important consequence of the length selection rule is that, at loop order $L = l(O_l) - l(O_s) + 1$, only the $(L + 1)$-particle cut can contribute \cite{8}. For example, the three-particle cut depicted in Figure 8(a) is the only cut that can contribute to $\gamma_{F_3 \rightarrow (\varphi^2 F^2)_1}^{\text{UV}(2)}$. The $(L + 1)$-particle cut can then be evaluated using a four-dimensional tree-level amplitudes, making the calculation much simpler than that of a generic $L$-loop anomalous dimension matrix element. This observation, noted in Ref. \cite{8}, makes it straightforward to evaluate certain two-loop SMEFT anomalous dimensions solely from three-particle cuts \cite{27}.

4.2 Zeros from vanishing one-loop rational terms

Next, we show that the vanishing of many one-loop amplitudes and rational terms found in Section 3 yields additional zeros in the two-loop anomalous-dimension matrix of our theory. Somewhat surprisingly, this sometimes involves a cancelation between different contributions to the logarithms from one-loop terms in the cut. We will explain how this relates to the scheme dependence of two-loop anomalous dimensions.

4.2.1 $O_{\psi^4} \leftarrow O_{D_2 \varphi^4}$

We begin by determining the renormalization of $O_{\psi^4}$ and $O_{\psi^4}$ by $O_{(D_2 \varphi^4)}$, which we denote by $O_{\psi^4} \leftarrow O_{(D_2 \varphi^4)}$. To extract the anomalous dimensions, we examine cuts of amplitudes with four external quarks. We can readily prove that these anomalous dimension matrix elements are zero at two loops in our model. The contributing cuts would be

1. the three-particle cut between the five-point dimension-four tree amplitude and the five-point $(D_2 \varphi^4)_1$ amplitude,
2. the two-particle cut between the four-point dimension-four one-loop amplitude and the four-point $(D_2 \varphi^4)_1$ tree, and
3. the two-particle cut between the four-point dimension-four tree and the four-point $(D_2 \varphi^4)_1$ one-loop amplitude.

In all cases the external particles must be four fermions to match the desired operator.

In case (1), the five point amplitude containing the operator $(D_2 \varphi^4)_1$ must have two external fermions, but since the Yukawa couplings are set to zero in our simplified model, the $(D_2 \varphi^4)_1$ tree must have at least four scalars, prohibiting the required three-scalar two-fermion amplitude. For case (2), the $(D_2 \varphi^4)_1$ tree must again have two fermions, so that there are no valid diagram and the cut vanishes.
Figure 5. The (12)-channel (a) and (34)-channel (b) unitary cuts which determine the renormalization of $O_{\psi^4}$ by $O_{(D^2\varphi^4)}$ or $O_{(D^2\varphi^4)}$. The (23)- and (14)-channel cuts are given by the exchange of legs 2 and 4. In each, the darker blobs indicate a higher-dimension operator insertion, and the vertical (blue) dashed line indicates the integral over phase space of the particles crossing the cut.

The vanishing of case (3) relies on our knowledge of the one-loop amplitudes with an operator insertion $O_{(D^2\varphi^4)}$, given in Appendix B. In this case, the only $O_{(D^2\varphi^4)}$ one-loop amplitude that can be inserted into the cut is the two-scalar two-fermion amplitude—as in Figure 5—which is zero for this operator. Therefore, all possible contributing cuts evaluate to zero. Since $O_{(D^2\varphi^4)}$ does not renormalize $O_{\varphi^4\psi^4}$ or $O_{\psi^4}$ at one loop, which otherwise produce terms on the left-hand-side of Eq. (2.37), the vanishing of the three types of cuts implies that the two-loop anomalous-dimension matrix element is also zero.

Next, consider the case $O_{(\psi^4)} \leftarrow O_{(D^2\varphi^4)}$, which we also show has a zero entry in the anomalous dimension matrix of our simplified model. We organize the calculation into the three types of cuts as in the previous case, with the only difference being that, in case (3), the one-loop amplitude with an insertion of $O_{(D^2\varphi^4)}$, and with two scalars and two fermions as external particles is nonzero, and in fact has a UV divergence. While the presence of nonzero cuts, shown diagrammatically in Figure 5, might seem to imply that the two-loop anomalous dimension must be nonzero, we will show that it actually evaluates to zero as well.

Using the external state $\langle 1^+2^-3^+4^- \mid$ and setting $O_i = O_{(D^2\varphi^4)}$, Eq. (2.37) reduces to

$$\begin{align}
\gamma_{\psi^4 \leftarrow (D^2\varphi^4)}^{UV(2)} F^{(0)}_{\psi^4} + \gamma_{(D^2\varphi^4) \leftarrow (D^2\varphi^4)}^{UV(1)} F^{(1)}_{(D^2\varphi^4)} \\
= -\frac{1}{\pi} (\mathcal{M}_{2\rightarrow 2}^{12} + \mathcal{M}_{2\rightarrow 2}^{14} + \mathcal{M}_{2\rightarrow 2}^{23} + \mathcal{M}_{2\rightarrow 2}^{34})^{(0)} \otimes \text{Re} F^{(1)}_{(D^2\varphi^4)}
\end{align}$$

where on the right-hand side we only find cuts of the form in Figure 5 with an $O_{(D^2\varphi^4)}$ insertion, and the (13) and (24) channels are not allowed. For instance the (12)-channel
The relevant tree and renormalized one-loop amplitudes needed to construct the cut are (including the color factors):

\[ A^{(0)}(1^+ \bar{\psi}^2 - \ell \bar{\psi}^2) = T^a_{i_2i_1} T^a_{i_4i_3} g^2 \frac{\langle 23 \rangle [13]}{s} , \]  

\[ A^{(1)}_{(D^2 \varphi^4)^2}(1^+ \bar{\psi}^2 - \ell \bar{\psi}^2) = T^a_{i_2i_1} T^a_{i_4i_3} \frac{g^2}{9} \langle 23 \rangle [13](3 \log(-s/\mu^2) + 8) , \]  

where again the flavor indices have been dropped for simplicity. Note the form of Eq. (4.3) provides a nontrivial check on the phase space integral on the right-hand side: \( A^{(1)}_{(D^2 \varphi^4)^2} \) contains terms proportional to \( \log(-s/\mu^2) \), which, after the phase-space integral, must cancel against terms in \( A^{(1)}_{(D^2 \varphi^4)^2} \).

We can readily evaluate the cut by relabeling the amplitudes (4.4)–(4.5) and applying the spinor parametrization (2.25) to the scalars crossing the cut. This yields an integral with no poles in \( z = e^{i\phi} \), other than the pole at zero. This can be seen by the fact that all spinor products in \( A^{(0)} \) are either proportional to \( e^{i \phi} \) or else have no \( \phi \) dependence under our parametrization, whereas \( A^{(1)}_{(D^2 \varphi^4)^2} \) only has a pole in \( s \). This makes the \( \phi \) integral trivial to evaluate, resulting in:

\[ \int_0^{\frac{\pi}{2}} d\theta \frac{\bar{g}^4}{18} \langle 24 \rangle [13] \sin^3(2\theta)(3 \log(-s/\mu^2) + 8) T^a_{i_2i_1} T^a_{i_4i_3} \]

\[ = \frac{\bar{g}^4}{27} \langle 24 \rangle [13](3 \log(-s/\mu^2) + 8) T^a_{i_2i_1} T^a_{i_4i_3} , \]  

for the (12)-channel cut. The (34)-channel cut gives the same result, while the other cuts yield the same result with legs two and four exchanged. Summing over the three
other channels, we exactly match the second term on the left-hand side of Eq. (4.1), since
\[ \gamma_{(D\psi^2\psi^2)}^{(1)} = \tilde{g}^2/3 \] and
\[ A_{(D\psi^2\psi^2)}^{(1)} = \frac{2\tilde{g}^2}{9}(24)[13](3\log(-s/\mu^2) + 8)T_{i21}^a T_{i4}^a - (2 \leftrightarrow 4). \] (4.7)
Therefore the cuts exactly cancel all terms on the left-hand side of Eq. (4.1) involving
the one-loop anomalous dimensions and form-factors, leaving \( \gamma_{\psi^4 \rightarrow (D^2\varphi^4)}^{(2)} F_{\psi^4}^{(0)} = 0 \). Thus
the two-loop anomalous dimension \( \gamma_{\psi^4 \rightarrow (D^2\varphi^4)}^{(2)} \) is zero.

In fact, we could have come to this conclusion simply by examining the form of
the one-loop amplitudes in Eqs. (4.5) and (4.7). First, note the two-loop anomalous
dimension must be \( \tilde{g}^4 \) times a number (i.e., it does not have any kinematic dependence).
Logarithmic terms resulting from the cut on the right-hand side of (4.1) must therefore
cancel against logarithmic terms in \( A_{(D\psi^2\psi^2)}^{(1)} \). Since both one-loop form factors are
proportional to the factor \( (3\log(-s/\mu^2) + 8) \), and since this term can be pulled out
of the phase-space integral on the right-hand side of Eq. (4.1), the cancellation of the
logarithmic terms implies cancellation of the rational term as well. Thus, even though
there are nonzero cuts, there can be no remaining rational term that leads to a nonzero
two-loop anomalous dimension.

At this point, the vanishing of the two-loop anomalous dimensions due to the
cancellation of one-loop rational terms might seem accidental. However, one must
remember that such local rational pieces are scheme dependent and can be adjusted by
adding finite local counter-terms. As described in Section 3, the rational terms of both
one-loop amplitudes in (4.5) and (4.7) can be set to zero by such finite counterterms,
which would also result in \( \gamma_{\psi^4 \rightarrow (D^2\varphi^4)}^{(2)} = 0 \). For this particular example, it just so
happened that the naive MS scheme has zero anomalous dimension, but next we will
see that this is not always the case.

As a cross-check, we have verified that the Eq. (2.32) is also satisfied. The crucial
substitution \( \log(-s/\mu^2) \to \log(-s/\mu^2) - i\pi \), is required in the right-hand side of that
equation, coming from the analytic continuation of the amplitude from the Euclidean
region to the correct physical region, which must be carried out for use in Eqs. (2.29)–
(2.31).

4.2.2 \( O_{D^2\varphi^4} \leftarrow O_{(\psi^4)} \)

This section will provide our first example of nonzero two-loop anomalous dimension
matrix elements in \( \overline{\text{MS}} \), while demonstrating how an appropriate choice of scheme, i.e.
choice of finite local counterterms, can eliminate the two-loop anomalous dimensions
of this example.

We will begin with the calculation in \( \overline{\text{MS}} \). Again, there is no three-particle cut, due
to the particle content of the two types of operators in question. Using the external
state \(|1_\varphi 2_\varphi 3_\bar{\varphi} 4_\bar{\varphi}\rangle\) and setting \(O_i \rightarrow O_{(\psi^4)_1}\), Eq. (2.37) becomes

\[
\gamma^\text{UV(2)}_{(D^2\varphi^4)_1} \rightarrow (\psi^4)_1 F_{(D^2\varphi^4)_1}^{(0)} + \gamma^\text{UV(2)}_{(D^2\varphi^4)_2} \rightarrow (\psi^4)_1 F_{(D^2\varphi^4)_2}^{(0)} + \gamma^\text{UV(1)}_{(D^2\varphi^2_\psi^2)_2} \rightarrow (\psi^4)_1 F_{(D^2\varphi^2_\psi^2)_2}^{(1)} = \frac{1}{\pi} (M_{2\rightarrow 2}^{12} + M_{2\rightarrow 2}^{14} + M_{2\rightarrow 2}^{23} + M_{2\rightarrow 2}^{34})^{(0)} \otimes \Re F_{(\psi^4)_1}^{(0)}.
\]

As for the previous example, the logarithmic terms in the cuts must cancel against terms in the amplitude \(F_{(D^2\varphi^2_\psi^2)_2}^{(1)}\) on the left-hand side of the equation. Since we are dealing with four-point matrix elements we will again set \(q = 0\). Then the one-loop amplitudes required for this example are

\[
A_{(\psi^4)_1}^{(1)}(1_\varphi 2_\varphi 3_\bar{\varphi} 4_\bar{\varphi}) = \frac{2g^2}{9} (23)[13](3 \log(-s/\mu^2) - 2) T_{i2i1}^a T_{i4i3}^a,
\]

\[
A_{(D^2\varphi^2_\psi^2)_2}^{(1)}(1_\varphi 2_\varphi 3_\bar{\varphi} 4_\bar{\varphi}) = \frac{2g^2}{9} (t - u)(3 \log(-s/\mu^2) - 5) T_{i2i1}^a T_{i4i3}^a + (2 \leftrightarrow 4),
\]

and the tree-level amplitudes needed are in Eq. (4.4) along with

\[
A_{(D^2\varphi^4)_1}^{(0)}(1_\varphi 2_\varphi 3_\bar{\varphi} 4_\bar{\varphi}) = t \delta_{i2i1} \delta_{i4i3} + s \delta_{i4i1} \delta_{i2i3},
\]

\[
A_{(D^2\varphi^4)_2}^{(0)}(1_\varphi 2_\varphi 3_\bar{\varphi} 4_\bar{\varphi}) = 2s \delta_{i2i1} \delta_{i4i3} + 2t \delta_{i4i1} \delta_{i2i3},
\]

which are shown in a slightly different basis of color factors than those shown in the appendix. The phase-space integral is evaluated in the same manner as the previous examples, with the result of the (12)-channel cut being

\[
-\frac{1}{\pi} \int d\text{LIPS}_2 \sum_{h_1, h_2} A^{(0)}(1_\varphi 2_\varphi - \ell_1 h_1 - \ell_2 h_2) A^{(1)}_{(\psi^4)_1}(\ell_2 h_2, \ell_1 h_1; 3_\bar{\varphi} 4_\bar{\varphi}) = -\frac{2}{2\pi} g^4 (t - u)(3 \log(-s/\mu^2) - 2) T_{i2i1}^a T_{i4i3}^a.
\]
After summing over all channels and subtracting the contribution of $\gamma_{(D^2\varphi^4)_{1}\leftarrow(\psi^4)}^{UV(1)} F_{(D^2\varphi^2\psi^2)^2}$ in Eq. (4.8)—thus canceling the logarithmic terms—the two-loop anomalous dimensions are given by

$$\gamma_{(D^2\varphi^4)_{1}\leftarrow(\psi^4)}^{UV(2)} = -\frac{4}{9}g^4(t-u)T_{ij}T_{kl} + (2 \leftrightarrow 4).$$

Applying the color Fierz identity,

$$T_{ij}T_{kl} = \delta_{ij}\delta_{kl} - \frac{1}{N}\delta_{ij}\delta_{kl},$$

and solving for the two-loop anomalous dimensions, we find

$$\gamma_{(D^2\varphi^4)_{1}\leftarrow(\psi^4)}^{UV(2)} = -\frac{4g^4(N-2)}{9N},$$

$$\gamma_{(D^2\varphi^4)_{1}\leftarrow(\psi^4)}^{UV(2)} = \frac{2g^4(2N-1)}{9N},$$

in the $\overline{\text{MS}}$ scheme. Although these anomalous dimension matrix elements are nonzero in the $\overline{\text{MS}}$ scheme, a simple rational shift of the coefficients $c(D^2\varphi^4)_1$, $c(D^2\varphi^4)_2$, and $c(D^2\varphi^2\psi^2)_2$ can set them to zero. This is accomplished by the following shifts in the coefficients:

$$c(D^2\varphi^4)_1 \rightarrow \tilde{c}(D^2\varphi^4)_1 = c(D^2\varphi^4)_1 + \frac{10g^2(N-2)}{9N}c(D^2\varphi^2\psi^2)_2,$$

$$c(D^2\varphi^4)_2 \rightarrow \tilde{c}(D^2\varphi^4)_2 = c(D^2\varphi^4)_2 + \frac{5g^2(2N-1)}{9N}c(D^2\varphi^2\psi^2)_2,$$

$$c(D^2\varphi^2\psi^2)_2 \rightarrow \tilde{c}(D^2\varphi^2\psi^2)_2 = c(D^2\varphi^2\psi^2)_2 - \frac{2g^2}{9}c(\psi^4)_1,$$

which yields

$$\tilde{\gamma}_{(D^2\varphi^4)_{1}\leftarrow(\psi^4)}^{UV(2)} = 0,$$

$$\tilde{\gamma}_{(D^2\varphi^4)_{2}\leftarrow(\psi^4)}^{UV(2)} = 0,$$

where the tilde indicates the modified scheme. The shifts above are equivalent to a finite renormalization of the operator at one loop. Generally this can be achieved by choosing the rational terms in $\gamma_{(D^2\varphi^2\psi^2)_{2}\leftarrow(\psi^4)}^{UV(1)} F_{(D^2\varphi^2\psi^2)^2}$ to match those of the cuts. In our particular example we set the rational terms of both (4.9) and (4.10) to zero. We briefly comment below on the consequences of this redefinition for the two-loop RG running of the operators involved.

While we do not present the analogous calculation for $O(\psi^4)_2$ here, by inspecting Table 3, we can deduce that the two-loop anomalous dimensions $\gamma_{(D^2\varphi^4)_{1}\leftarrow(\psi^4)}^{UV(2)}$ and $\gamma_{(D^2\varphi^4)_{2}\leftarrow(\psi^4)}^{UV(2)}$ can also be set to zero with the appropriate choice of finite counterterms.
4.2.3 General comments about scheme redefinition

As mentioned above, the scheme choice that sets some two-loop anomalous dimensions to zero is equivalent to a finite renormalization of the operators

$$\tilde{O}_i = Z_i^{\text{fin}} O_j , \quad \text{where} \quad Z_i^{\text{fin}} = \delta_{ij} + f_{ij}(\alpha^{(4)}) ,$$

and the quantity $f_{ij}$ is finite and has a perturbative expansion starting at one loop, $f_{ij}(\alpha^{(4)}) = f_{ij}^{(1)} + \cdots$. As usual, the redefinition of the coefficients, $\tilde{c}_i = Z_i^{\text{fin}(c)} c_j$ is given by the inverse, $Z_i^{\text{fin}(c)} = (Z_i^{\text{fin}})^{-1}$. The effect of such a scheme redefinition can be easily analyzed using the unitarity-based formalism employed in this paper. Since the coupling dependence of $f_{ij}$ starts at one loop we have that $\tilde{\Delta}_{ij}^{(1)} = \Delta_{ij}^{(1)}$. Similarly, writing Eq. (2.37) for the redefined operator

$$[\Delta \tilde{\gamma}_{ij}^{(1)} + \delta_{ij} \beta^{(1)}] \text{Re} \tilde{F}_j^{(1)} + [\Delta \tilde{\gamma}_{ij}^{(2)} + \delta_{ij} \beta^{(2)} \partial] \tilde{F}_j^{(0)} = -\frac{1}{\pi} \left[ \text{Re}(\mathcal{M}) \text{Re}(\tilde{F}_i) \right]^{(2)} .$$

and using Eqs. (4.20) and (4.21) together with Eqs. (2.22) and (2.37), while keeping in mind that the infrared anomalous dimensions are not changed by redefining the scheme, we find the relation between the two-loop anomalous dimensions in the two schemes,

$$\tilde{\gamma}_{ij}^{\text{UV}(2)} = \gamma_{ij}^{\text{UV}(2)} + f_{ik}^{(1)} \gamma_{kj}^{\text{UV}(1)} - f_{ik}^{(1)} \gamma_{kj}^{\text{UV}(1)} - \beta^{(1)} \partial f_{ij}^{(1)} .$$

In general, one would like to solve this equation for $f_{ik}^{(1)}$ to get as many vanishing entries as possible in $\tilde{\gamma}_{ij}^{\text{UV}(2)}$.

We have explicitly verified Eq. (4.23) in the examples above, where we set the anomalous dimensions of the form $\tilde{\gamma}_{ij}^{\text{UV}(2)}_D^{D^2 \varphi^4}$ to zero by appropriately choosing $f_{ik}^{(1)}$ and $f_{ik}^{(1)}$. In addition, $f_{ik}^{(1)}$ vanished, which from Eq. (4.23) implies the absence of a term induced by the $\beta$-function in the new two-loop anomalous dimension. On the other hand, it is clear from Eq. (4.23) that the finite renormalizations will induce some additional running in the two-loop anomalous dimensions $\tilde{\gamma}_{ij}^{\text{UV}(2)}_D^{D^2 \varphi^4}$ and $\tilde{\gamma}_{ij}^{\text{UV}(2)}_D^{D^2 \varphi^4}$, proportional to the one-loop beta function and $\partial f_{ij}^{(1)}$. However, this additional running is harmless, since those operators already mix at one loop. Furthermore, the corresponding entries in the two-loop anomalous-dimension matrix receive contributions from both two- and three-particle cuts that have no a priori reason to vanish, so we expect them in any case to run. In summary, our scheme choice prevents certain operators from mixing at two-loops at the expense of modifying the running of operators that, in any case, mix at one loop in the original scheme.
Figure 7. (12)-channel (a) and (34)-channel (b) unitary cuts which determine the renormalization of $O_{(\varphi^2 F^2)_1}$ and $O_{(\varphi^2 F^2)_2}$ by $O_{(\psi^4)_1}$ or $O_{(\psi^4)_2}$. There are no t-channel cuts for this process. In each diagram, the darker blobs indicate a higher-dimension operator insertion, and the dashed line indicates the integral over phase space of the particles crossing the cut.

4.3 Zeros from color selection rules

This section will provide an example of another type of selection rule, wherein a mismatch between the color of the cuts and the color of the target operators prevents renormalization at two loops.

4.3.1 $O_{\varphi^2 F^2} \leftarrow O_{\psi^4}$

For this example we choose the external state to be $\langle 1 \varphi^2 \bar{\varphi}^2 3^+ 4^+ |$, under which both $O_{(\varphi^2 F^2)_1}$ and $O_{(\varphi^2 F^2)_2}$ are nonzero. Using this state and setting $O_i \rightarrow O_{(\psi^4)_1}$, Eq. (2.37) reduces to

$$\gamma_{(\varphi^2 F^2)_1 \leftarrow (\psi^4)_1}^{\text{UV}(2)} F_{(\varphi^2 F^2)_1}^{(0)} + \gamma_{(\varphi^2 F^2)_2 \leftarrow (\psi^4)_1}^{\text{UV}(2)} F_{(\varphi^2 F^2)_2}^{(0)} + \gamma_{(D\varphi^2 \bar{\psi}^2)_2 \leftarrow (\psi^4)_1}^{\text{UV}(1)} F_{(D\varphi^2 \bar{\psi}^2)_2}^{(1)} = -\frac{1}{\pi} \left( (\mathcal{M}_{2\rightarrow 2}^{12})^{(0)} \otimes \text{Re} F_{(\psi^4)_1}^{(1)} + (\mathcal{M}_{2\rightarrow 2}^{34})^{(0)} \otimes \text{Re} F_{(\psi^4)_1}^{(1)} \right).$$

(4.24)

Naively there would be the additional term $\gamma_{(F^3 \leftarrow (\psi^4)_1)}^{\text{UV}(2)} F_{F^3}^{(0)}$ on the left-hand-side of the equation, since $O_{F^3}$ produces a nonzero tree amplitude with the state $\langle 1 \varphi^2 \bar{\varphi}^2 3^+ 4^+ |$. However, as was discussed in Section 4.1, the length and particle content of $O_{(\psi^4)_1}$ requires $\gamma_{(F^3 \leftarrow (\psi^4)_1)}^{\text{UV}(2)} = 0$. Setting $q = 0$, the (12)-channel cut of the above equation is

$$(\mathcal{M}_{2\rightarrow 2}^{12})^{(0)} \otimes \text{Re} F_{(\psi^4)_1}^{(1)} = \int d\text{LIPS}_2 \sum_{h_1, h_2} A^{(0)}(1^+ 2^+ \varphi^2 - \ell_1 h_1 - \ell_2 h_2) A^{(1)}(\ell_2 h_2, \ell_1 h_1 3^+ 4^+) \text{Re} F_{(\psi^4)_1}^{(1)}.$$

(4.25)

and the (34)-channel cut is

$$(\mathcal{M}_{2\rightarrow 2}^{34})^{(0)} \otimes \text{Re} F_{(\psi^4)_1}^{(1)} = \int d\text{LIPS}_2 \sum_{h_1, h_2} A^{(0)}(3^+ 4^+ - \ell_1 h_1 - \ell_2 h_2) A^{(1)}(\ell_2 h_2, \ell_1 h_1 1^+ 2^+) \text{Re} F_{(\psi^4)_1}^{(1)}.$$

(4.26)
The (34)-channel cut vanishes, because the amplitude $A^{(0)}(3^+4^- - \ell_1 - \ell_2)$ is zero for all helicities of the fermions crossing the cut. This vanishing is required for the consistency of the logarithmic terms: $A_{(\psi)_1}^{(1)}(\ell_2 \frac{h_2}{\psi} \ell_1 \frac{h_1}{\psi} 1 \bar{2})$ includes a term proportional to $\log(-s/\mu^2)$, but there is no term on the left-hand side that can cancel it, since $F_{(D\varphi^2\bar{\psi}^2)_2}(1 \bar{2} 3^+4^+)$ is purely rational. The one-loop amplitudes needed for this calculation are

$$A_{(\psi)_1}^{(1)}(1^+ \bar{2} 3^+4^+) = -\frac{g^2 s[14][24]}{3(34)^2} [T^{a_3}_1, T^{a_4}_1]_{\ell_2 \ell_1},$$

$$A_{(\psi)_1}^{(1)}(1^- \bar{2} 3^+4^+) = -\frac{g^2 s[23][24]}{3(34)} [T^{a_3}_1, T^{a_4}_1]_{\ell_2 \ell_1},$$

$$A_{(D\varphi^2\bar{\psi}^2)_2}^{(1)}(1 \bar{2} 3^+4^+) = \frac{g^2 s(t - u)}{3(34)^2} [T^{a_3}_1, T^{a_4}_1]_{\ell_2 \ell_1},$$

while the tree-level amplitudes needed for the cut calculation are (4.4) and its conjugate. The phase-space integrals are carried out in the same manner as the previous example, with the simplification that the functions are now entirely rational. The result of the phase-space integral is

$$- \frac{1}{\pi} \int dLIPS \sum_{h_1, h_2} A^{(0)}(1^+ \bar{2} 3^+4^+) \cdot A_{(\psi)_1}^{(1)}(\ell_2 \frac{h_2}{\psi} \ell_1 \frac{h_1}{\psi} 3^+4^+) = -\frac{2\bar{g}^4 s(t - u)}{9((34))^2} [T^{a_3}_1, T^{a_4}_1]_{\ell_2 \ell_1} = \gamma^{(D\varphi^2\bar{\psi}^2)_2 \leftarrow (\psi)_1 A_{(D\varphi^2\bar{\psi}^2)_2}^{(1)}.$$

Thus the phase-space integral exactly cancels against this term from the left-hand side of Eq. (4.24), meaning the two-loop anomalous dimension is again zero.

Interestingly, this can also be seen without looking at the kinematic content of the cuts on the right-hand side of Eq. (4.24). Since the color of both $O_{(\varphi^2F^2)_1}$ and $O_{(\varphi^2F^2)_2}$ are symmetric in $T^3$ and $T^4$, no combination of the two can produce the color factor $[T^{a_3}_1, T^{a_4}_1]_{\ell_2 \ell_1}$. Since this is the color of $A_{(D\varphi^2\bar{\psi}^2)_2}^{(1)}(1 \bar{2} 3^+4^+)$, and the color of $A_{(\psi)_1}^{(1)}(1^+ \bar{2} 3^+4^+)$ is also anti-symmetric under the exchange of 3 and 4, we can see directly from the color that neither of these terms can contribute to the two-loop anomalous dimension, and therefore must cancel. As in the previous example, we can extend this argument trivially to the operator $O_{(\psi^4)_2}$, since its two-fermion two-vector-boson amplitude is proportional to that of $O_{(\psi^4)_1}$, in this case, the only difference on the left-hand side would being the value of $\gamma^{(D\varphi^2\bar{\psi}^2)_2 \leftarrow (\psi^4)_1}$ versus $\gamma^{(D\varphi^2\bar{\psi}^2)_2 \leftarrow (\psi^4)_1}$, but the color again ensures all terms must cancel, leaving

$$\gamma^{(D\varphi^2\bar{\psi}^2)_2 \leftarrow (\psi^4)_1} = 0,$$

$$\gamma^{(D\varphi^2\bar{\psi}^2)_2 \leftarrow (\psi^4)_2} = 0.$$
Figure 8.  (a) Unitary cut which determines the renormalization of $O_{F^3}$ by $O_{(\phi^2 F^2)_2}$ or $O_{(\phi^2 F^2)_2}$. Note this form factor requires $q \neq 0$, and the double-lined arrow indicates this insertion of additional off-shell momentum from the operator. (b) Unitarity cut which determines the renormalization of $O_{(\psi^4)_2}$ and $O_{(\psi^4)_2}$ by $O_{(\phi^2 F^2)_2}$ or $O_{(\phi^2 F^2)_2}$. In each, the darker blobs indicate a higher-dimension operator insertion, and the dashed line indicates the integral over phase space of the particles crossing the cut.

Here we focused on a simple example in which the color can preclude renormalization. In more general cases, one can directly inspect the color of the amplitudes that compose the cuts contributing to a given anomalous dimension and determine whether a given operator can yield a nonzero contribution. Note that this is more efficient than studying the color of individual Feynman diagrams, since the color decomposed amplitudes have fewer color structures.

It is worth noting that, as mentioned in Section 3, the nonzero rational amplitudes (4.27)–(4.29) can be set to zero by introducing finite counterterms proportional to $c_{(\psi^4)_2} O_{F^3}$ and $c_{(D\phi^2 \psi^2)_2} O_{F^3}$, respectively. However, since these are non-local amplitudes, doing so introduces nonzero terms for other amplitudes, in particular any amplitudes where $O_{F^3}$ produces a nonzero tree-level amplitude. This would introduce a great deal of confusion—for example, if we were to introduce a counterterm to cancel (4.27), we would then need to include additional cuts on the right-hand side of Eq. (4.24), including three-particle cuts and cuts with nontrivial IR dependence. Canceling either Eq. (4.27) or Eq. (4.29) with such a counterterm would also spoil the argument of Section 4.1, as the $O_{F^3}$ self-renormalization would contribute in a nontrivial way. Therefore we would have to include the term $\gamma_{F^3 \rightarrow (\psi^4)}^{UV(2)} F_{F^3}^{(0)}$ on the left-hand side of Eq. (4.24) as well. For all of the above reasons, we choose not to implement these finite shifts. It is interesting however, that even though the rational terms remain in this example, the structure of the color precludes renormalization at two loops.

4.4 Outlook on additional zeros

The previous sections have demonstrated numerous zeros in the two-loop anomalous dimension matrix, summarized in Table 4. However, the previous examples are by no means exhaustive, and more zeros may exist. The large number of zeros in the one-loop amplitudes (Table 3) implies that when calculating two-loop anomalous dimensions, the
Table 4. Structure of the two-loop anomalous dimension matrix $\gamma_{ij}^{(2)}$ due to the collected rules outlined in this section. A $\emptyset$ indicates there are no contributing two-loop diagrams, whereas 0 alone indicates that there are one-loop diagrams that could contribute, but the anomalous dimension evaluates to zero. A 0* indicates the result is nonzero in $\overline{\text{MS}}$, but set to zero by introducing the appropriate finite counterterms. Shading indicates the entry depends only on the three-particle cut, due to either the length selection rules of Section 4.1 or the vanishing of the relevant one-loop amplitudes. As for Table 2, the operators labeling the rows are renormalized by the operators labeling the columns.

two-particle cut formed from the dimension-four tree and the dimension-six one-loop amplitude will not contribute. In some cases, the only contribution will come from the three-particle cut. Examples of this include the renormalization of $\mathcal{O}_{F3}$ by $\mathcal{O}_{(\phi^2 F^2)_1}$ or $\mathcal{O}_{(\phi^2 F^2)_2}$, and the renormalization of $\mathcal{O}_{(\psi^4)_1}$ and $\mathcal{O}_{(\psi^4)_2}$ by $\mathcal{O}_{(\phi^2 F^2)_1}$ or $\mathcal{O}_{(\phi^2 F^2)_2}$. The cuts for these examples are depicted in Figure 8. While it may seem that there is no reason to expect any given three-particle cut to evaluate to zero, it is possible that a detailed inspection may find that helicity selection rules [7] or angular momentum selection rules [9] set certain cuts to zero. For a generic entry, the collection of these rules and the rules laid out in the sections above greatly simplify the calculation of the two-loop anomalous dimensions by eliminating one or more required unitary cuts, and
one might expect that overlapping rules will conspire to eliminate all possible cuts and set additional entries in Table 4 to zero.

## 5 Implications for the SMEFT

In this section we describe the overlap of our theory with the SMEFT, and we explain how our calculations directly confirm a large number of the one-loop anomalous dimensions computed in Refs. [4]. We also comment on two-loop zeros and the coupling dependence of a subset of the two-loop anomalous-dimension matrix of the SMEFT.

### 5.1 Mapping our theory to the SMEFT

The full SMEFT is more intricate than the simplified model adopted here, as it includes multiple gauge groups and a number of additional operators. However, by keeping the gauge group to be a general $SU(N)$, and by leaving the identity of the fermions unspecified, we can access many of the entries of the anomalous-dimension matrix in the full SMEFT basis of operators used by Refs. [4]. In particular, since the Higgs transforms under $SU(2)$, setting $N = 2$ and the number of scalars $N_s = 1$ allows us to map to anomalous dimensions or four-point amplitudes from representatives of any of the classes of operators in Ref. [4] other than the $\psi^2 F_\varphi$ class ($\psi^2 X H$ in the notation of Ref. [4]). Since the scalar is in the fundamental representation that class necessarily involves both a left-handed fermion charged under $SU(2)$, as well as an uncharged right-handed fermion, which does not fit into our framework. By taking $N = 3$, parts of the anomalous dimensions in the SMEFT containing gluons can also be obtained. In principle, one can also compare anomalous dimensions for additional operators using more sophisticated embeddings of the Standard Model into $SU(N)$, including $U(1)$ charges (see e.g. Appendix IV of Ref. [51]), but we do not do so here.

By specifying the flavor of the fermions, we can map to a number of operators of the full basis used by Ref. [4] via different choices of gauge group and helicity. For example, by taking $N = 2$ and and left-handed helicity on the external states, we access the $SU(2)$ portions of the amplitudes involving the $q$ and $\bar{q}$ quark doublets, and map onto the operators $(\bar{q}\gamma_\mu q)(\bar{q}\gamma^\mu q)$ and $(\bar{q}\gamma_\mu \tau^I q)(\bar{q}\gamma^\mu \tau^I q)$. One remaining difference in our approach compared to the full SMEFT is that we treat the fermions as Dirac instead of Weyl. This causes factor of 2 differences in the $N_f$ terms of the renormalization of $\mathcal{O}_{(D\varphi^2\psi^2)}$ and $\mathcal{O}_{(\psi^4)}$ compared to Ref. [4], which need to be taken into account when comparing. While our simplified model avoids having to deal with $\gamma_5$, the generalized unitarity method has been applied to such cases as well [29]. At one loop, the issue of Weyl versus Dirac fermions is reduced to a question of which helicities to take in the state sum in Eq. (2.24).

Setting aside the issue of Weyl versus Dirac fermions, mapping onto the four-fermion operators of Ref. [4], $(\bar{l}\gamma_\mu l)(\bar{l}\gamma^\mu l)$, $(\bar{u}\gamma_\mu u)(\bar{u}\gamma^\mu u)$, and $(\bar{d}\gamma_\mu d)(\bar{d}\gamma^\mu d)$ is possible
as well, but requires some care, due to the presence of evanescent effects. In particular, for these cases the operator $\mathcal{O}_{(\psi^4)_2}$ is related to the operator $\mathcal{O}_{(\psi^4)_1}$ due to the $SU(N)$ Fierz identity (4.15)

\[
(\overline{\psi}_m \gamma^\mu T^a \psi_n)(\overline{\psi}_p \gamma_\mu T^a \psi_r) = (\overline{\psi}_m \gamma^\mu \psi_n)(\overline{\psi}_p \gamma_\mu \psi_r) \left( \delta_{ip} \delta_{im} \right) \frac{\delta_{im} \delta_{iip}}{N}.
\]

(5.1)

which, together with the Lorentz–Fierz relations for all left- or right-handed spinors

\[
(\overline{\psi}_L \gamma^\mu \psi_L)(\overline{\psi}_L \gamma_\mu \psi_L) = -(\overline{\psi}_L \gamma^\mu \psi_L)(\overline{\psi}_L \gamma_\mu \psi_L),
\]

\[
(\overline{\psi}_R \gamma^\mu \psi_R)(\overline{\psi}_R \gamma_\mu \psi_R) = -(\overline{\psi}_R \gamma^\mu \psi_R)(\overline{\psi}_R \gamma_\mu \psi_R),
\]

(5.2)

(where we raised the flavor indices for convenience) can be applied to eliminate the need for the $\mathcal{O}_{(\psi^4)_2}$ operator in Table 1:

\[
\mathcal{O}^{mnr}_{(\psi^4)_2} = (\overline{\psi}_m \gamma^\mu T^a \psi_n)(\overline{\psi}_p \gamma_\mu T^a \psi_r) = \mathcal{O}^{mnr}_{(\psi^4)_1} - \frac{1}{N} \mathcal{O}^{mnr}_{(\psi^4)_2}.
\]

(5.3)

when there are no additional group indices preventing the particle exchange (for example, the additional $SU(3)$ index prevents the reduction of $(\overline{q}\gamma^\mu \gamma^I q)(\overline{q}\gamma^\mu \gamma^I q)$ operator based on the $SU(2)$ Fierz identity). By choosing to implement Eq. (5.2) or not, we can map onto either the operators $(\overline{l}\gamma^\mu l)(\overline{l}\gamma^I l)$, $(\overline{u}\gamma^\mu u)(\overline{u}\gamma^I u)$, or $(\overline{d}\gamma^\mu d)(\overline{d}\gamma^I d)$, or onto the set of operators $(\overline{q}\gamma^\mu \gamma^I q)(\overline{q}\gamma^\mu \gamma^I q)$ and $(\overline{q}\gamma^\mu \gamma^I q)(\overline{q}\gamma^\mu \gamma^I q)$, respectively. Since we take all the fermions in our operators to be charged under the same gauge group, here we do not map onto the $(\overline{LR})(\overline{LR})$ or $(\overline{LR})(\overline{RL})$ subsets of the four-fermion operators, which require the presence of multiple gauge groups.

It is worth noting, that there are some simplifications in the SMEFT relative to our model with general gauge group. The symmetric color tensor $d^{abc}$ is zero in $SU(2)$, meaning that the operator $\mathcal{O}_{(\phi^2 F^2)_2}$ is identically zero. In addition, this implies the color factors for the two-vector, two-scalar or two-vector, two-fermion processes are related by $N\{T^{a_1} T^{a_2}\}_{i_1 i_2} = 2\delta^{a_1 a_2} \delta_{i_1 i_2}$, meaning the number of color-ordered amplitudes is reduced for those processes in the case of $SU(2)$.

### 5.2 Verification of one-loop anomalous dimensions

From our one-loop calculations and the relations described above we have verified entries from numerous classes of operators in the SMEFT, as summarized in Table 5, following the notation of Ref. [4]. This includes examples proportional to $g_3^2$, $g_2^2$, and $\lambda$. In this sense our operators are a representative sample of the full SMEFT, despite the simplified nature of our dimension-four Lagrangian. The direct agreement with results of Ref. [4] displayed in Table 5 provides a highly non-trivial check of the validity and the effectiveness of the approach used here.
Table 5. Checks on the one-loop anomalous dimensions calculated in Ref. [4] obtained from our calculations. The $\emptyset$ entries correspond to trivial cases were there are no contributing diagrams. The entries $\sqrt{3}$ and $\sqrt{2}$ are checked by setting the SU(N) group to SU(3) or SU(2), respectively. In both cases, only the pieces of the anomalous dimensions proportional to $g_2^2$ or $g_3^2$ are accessed by our amplitudes. The $\sqrt{2,\lambda}$ cases indicates that both terms proportional to $g_2^2$ and $\lambda$ are verified. Operators have been grouped according to whether the gauge dependence of the particle content is the same. As for the other tables, the operators labeling the rows are renormalized by the operators labeling the columns.

5.3 Two-loop implications

Next we briefly discuss the implications of the zeros in the two-loop anomalous dimensions of our simplifies model for the SMEFT. The selection rules of Section 4 set a number of entries strictly to zero, and restrict the coupling dependence of others. Our findings are summarized in Table 6. The full SMEFT anomalous dimensions include dependence on the Yukawa couplings, which are absent in our simplified theory, so some of the zeros uncovered above may be replaced by anomalous dimensions that depend on such couplings. Nevertheless, our results show that the coupling dependence of the anomalous dimensions is simpler than one might have expected, and that some of the entries are zero or do not have pure dependence on the gauge couplings. Though most of the strictly zero examples rely on the length selection rule, which does not depend on the gauge group or the presence of Yukawa couplings, the anomalous-dimension matrix element $\gamma^{(2)}_{HW\leftarrow qq}$ relies solely on the color selection rules. In this case, including Yukawa...
Table 6. Predictions for the zeros and coupling dependences of a representative selection of the SMEFT two-loop anomalous-dimension matrix, $\gamma_{ij}^{\text{UV}(2)}$. The notation for the operator labels follows that of [4]. The $g^4_2$ dependence of the entry labeled $0_y(\delta^4_2)$ vanishes using the appropriate counterterms at one loop. The operators labeling the rows are renormalized by the operators labeling the columns.

- $\emptyset$ : trivial zero, no contributing two-loop diagrams
- $0_y$ : zero predicted by the selection rules of Section 4
- $0_y(\delta^4_2)$ : only a three-particle cut is needed to evaluate $\gamma_{ij}^{\text{UV}(2)}$
- $0_y(\delta^4_2)$ etc. : only two-particle cuts available for the relevant diagrams
- $0(\delta^{\lambda})$, etc. : the selection rules of Section 4 forbid the stated coupling dependence
- $0_y$ : $\gamma_{ij}^{\text{UV}(2)}$ vanishes if Yukawa couplings are set to zero

and U(1) couplings will not affect this zero, as the cuts still cannot match the color of the target operator.

In addition to the zeros, we find that many of the entries only receive contributions from either three- or two-particle cuts, which should greatly simplify their computation. One interesting example is the element $\gamma_{qq\leftarrow HW}^{(2)}$, which only has a three-particle cut due to the vanishing of the one-loop amplitudes that would contribute to the two-particle cut. For this example, we have also checked the one-loop amplitudes with Yukawa and
U(1) couplings do not contribute. As can also be seen in Table 6, many entries vanish when the Yukawa couplings are set to zero. Many of these zeros are trivial due to the particle content of the operators involved, but in some cases a closer examination of the diagrams is required to see that only diagrams with Yukawa couplings will produce nonvanishing results.

Note that the operators in Table 6 are merely a representative set, in that all of the operators of the SMEFT are restricted by one or more of our selection rules, either in terms of which operators they can renormalize, or vice versa. In particular, the length selection rules apply independently of the gauge group or the presence of Yukawa couplings, which allows us to include operators of the classes $\psi^2 F \phi$ and $\psi^2 \phi^3$ in Table 6. We would also like to stress that our analysis of the structure of the two-loop anomalous dimensions is not an exhaustive study of the SMEFT anomalous dimensions. For this reason, we expect that there could be additional vanishings or structures that can be uncovered under closer scrutiny.

6 Conclusions

In this paper we applied on-shell methods to investigate the structure of the two-loop anomalous dimension matrix of dimension-six operators, in both a simplified model and in the SMEFT. At one loop, we used both the standard generalized unitarity method \cite{11} and the recently developed approach for extracting anomalous dimensions directly from unitarity cuts \cite{12}. At two loops, we find the latter method to be especially effective, with the former method providing one-loop amplitudes as inputs. As an initial step, we reorganized the basic equation for the two-loop anomalous dimension in the latter approach so as to simplify one-loop iterations. Using this equation, we revealed a number of vanishing contributions in the two-loop anomalous dimension matrix of the SMEFT. Our analysis was based on a simplified model without U(1) or Yukawa interactions. Nevertheless, as summarized in Table 6, by analyzing the overlap of our simplified model with the SMEFT we found that a remarkable number of SMEFT two-loop anomalous dimensions either vanish or have a simpler dependence on the Standard Model couplings than naively expected.

The structure we uncovered has a number of origins, including length selection rules, color selection rules, and zeros in the one-loop amplitudes with dimension-six operator insertions. Additional zeros arise from the choice of an $\overline{\text{MS}}$-like scheme which includes additional finite renormalizations designed to set various rational terms in one-loop amplitudes to zero. This suggests that there exist interesting schemes that make the structure of the renormalization-group running beyond one loop more transparent. The full implications of choosing such schemes clearly deserve further study.
Since one-loop amplitudes are used as input for the two-loop calculation, we have computed the full set of four-point amplitudes with dimension-six operator insertions in our simplified version of the SMEFT. As a byproduct, these amplitudes have allowed us to verify a large subset of the one-loop anomalous dimensions calculated in Refs. [4].

The zeros that we found in the two-loop anomalous dimension matrix relied on choosing examples with trivial infrared dependence, as well as a lack of a three-particle cut. However, the methods can be applied just as well to any generic anomalous dimension matrix element at two or higher loops. It would be interesting to investigate whether there are additional zeros at two loops beyond those we identified. The large number of zeros in the one-loop amplitudes restrict the number of cuts that can contribute, suggesting that other mechanisms, such as helicity or angular-momentum selection rules, may set the remaining cuts to zero in some cases.

The presented methods are quite general, and should be applicable to general EFTs. In addition, while we have focused on ultraviolet anomalous dimensions here, this method could equally be applied to the evaluation of infrared anomalous dimensions, such as the soft anomalous dimension, by the use of ultraviolet protected operators such as the stress-tensor or global symmetry currents. It would also be interesting to understand the implications, if any, of the vanishing of two-loop anomalous dimensions for the interference of Standard Model and higher-dimension operator matrix elements beyond tree level, in the presence of experimental cuts. Another obvious direction would be to include dimension seven and eight operators into the analysis [52].

In summary, we have demonstrated that the on-shell methods applied here are well suited for computing anomalous dimensions and associated scattering amplitudes at one and two loops. We used these methods to expose new structures in the guise of vanishing terms in the anomalous matrix of the SMEFT beyond one loop. Our analysis here was not exhaustive, so it is likely that further vanishing contributions and new structures exist at two loops and beyond. Our results also suggest that a judicious choice of renormalization scheme can help expose such structures.

A Integral reduction via gauge-invariant tensors

In this appendix we summarize the projection technique that we use to perform tensor reduction of loop integrals in Section 3. The same technique has been previously used in Refs. [31, 32] and is a convenient method for decomposing $D$-dimensional tensor loop integrands (or cuts) into a basis of scalar master integrals, in a way that makes dimensional regularization, and any associated chiral and evanescent issues relatively straightforward. In particular this technique is well suited to deal with integrals with high-rank numerators, which naturally arise in loop amplitudes with insertions of higher-dimension operators.

We start by noting that scattering amplitudes are gauge invariant and can therefore be decomposed into a basis of gauge-invariant tensors, $T_m$. For a given amplitude labeled by $i$ we have,

$$A_i^{(L)} = \sum_m A_{i,m}^{(L)}(k_j) T_m(k_j, \epsilon_j, u_j, \bar{u}_j), \quad (A.1)$$

where the coefficients, $A_{i,m}^{(L)}$, only depend on the external momenta, and all dependence on the polarization vectors or spinors is contained entirely within the basis tensors, $T_m$. The basis tensors for the various processes we consider in this paper are given below and in the supplementary material [34]. They are found by writing down the most general polynomials built from Lorentz invariant products of external polarizations, spinor and momenta and then demanding gauge invariance.

The desired coefficient of tensor $T_j$ can be extracted using a projector

$$P_n = c_{nm} T_m^*, \quad (A.2)$$

where $c_{nm}$ is the inverse of the matrix

$$m_{nm} = T_n^* \odot T_m. \quad (A.3)$$

Here the product $\odot$ corresponds to the state sum in Eq. (3.2), taken over all particles. The coefficient of the tensor is then simply given by

$$A_{i,m}^{(L)} = P_m \odot A_i^{(L)}. \quad (A.4)$$

The projectors for all processes consider in this paper are given explicitly in an ancillary file [34].

Once projected, any gauge invariant quantity can be summarized as a list of the coefficients corresponding to each basis tensor. In the case of a loop integrand or cut thereof, each coefficient is a rational function of scalar propagators and inverse propagators (and irreducible numerators beyond one loop). The integrals corresponding
to each term in the projected quantity are then in a form that can be reduced to a basis of master integrals using by integration by parts (IBP) relations. This can be done using by using IBP programs such as FIRE [33].

As described in Section 3, we can apply this procedure cut by cut to determine the coefficients of each gauge invariant tensor in the full amplitude.

**Basis tensors**

Basis tensors for the four-vector amplitudes are taken from [32], which we reproduce here. Beginning with the linearized field strength for each external particle:

\[ F_{i\mu\nu} \equiv k_{i\mu}\varepsilon_{i\nu} - k_{i\nu}\varepsilon_{i\mu} , \]

(A.5)

one can construct the following combinations,

\[
\begin{align*}
F^4_{st} &\equiv (F_1 F_2 F_3 F_4) , \\
F^4_{tu} &\equiv (F_1 F_4 F_2 F_3) , \\
F^4_{us} &\equiv (F_1 F_3 F_4 F_2) , \\
(F^s)^2 &\equiv (F_1 F_2)(F_3 F_4) , \\
(F^t)^2 &\equiv (F_1 F_4)(F_2 F_3) , \\
(F^u)^2 &\equiv (F_1 F_3)(F_4 F_2) ,
\end{align*}
\]

(A.6)

where parentheses one the right-hand side of the above equations indicate taking the trace over adjacent Lorentz indices. The four-vector basis tensors are then given by

\[
\begin{align*}
T^\text{tree}_{\text{vv}} &= -\frac{1}{2}((F^s)^2 + (F^t)^2 + (F^u)^2) + 2 (F^4_{st} + F^4_{tu} + F^4_{us}) , \\
T^{++} &= -2 F^4_{st} + \frac{1}{2}((F^s)^2 + (F^t)^2 + (F^u)^2) , \\
T^{+++} &= -T^{F^3} - (F^4_{tu} - F^4_{us}) (s-t) + (F^4_{st} - \frac{1}{4}((F^s)^2 + (F^t)^2 + (F^u)^2)) (s+t) , \\
T^{-++} &= (F^2)^2 - (F^t)^2 + 2 (F^4_{tu} - F^4_{us}) , \\
T^{++-} &= 2 F^4_{st} - \frac{1}{2}((F^s)^2 + (F^t)^2 - (F^u)^2) , \\
T^{+--} &= -(2 F^4_{st} + \frac{3}{2}((F^s)^2 + (F^t)^2 + (F^u)^2)) (s+t) + 2 (F^4_{us} (3 s + t) + F^4_{tu} (s + 3 t)) , \\
T^{--} &= -(2 F^4_{st} - \frac{1}{2}((F^s)^2 + (F^t)^2 + (F^u)^2)) (s-t) + 2 (F^4_{tu} - F^4_{us}) (s+t) ,
\end{align*}
\]

(A.7)

where the \( v \) labels signifies that a leg is a vector boson, and \( T^{F^3} \) is proportional to the \( F^3 \) amplitude [53]:

\[ T^{F^3} = -istA^{(0)}_{F^3} = -istu \left( \frac{(F^2)^2}{4s^2} + \frac{(F^2)^2}{4t^2} + \frac{(F^2)^2}{4u^2} - \frac{g_1 g_2 g_3 g_4}{(stu)^2} \right) , \]

(A.8)

where \( g_i \equiv (k_{i+1} F_i k_{i-1}) \). We note that we have written this expression in an explicitly gauge-invariant form at the expense of manifest locality. These tensors are nonzero only under the indicated (and parity conjugate) helicity configurations, along with cyclic permutations. \( T^\text{tree}_{\text{vv}} \) is nonzero for helicities \((1^{--}2^{++}3^{+}4^{+}), (1^{--}2^{+}3^{+}4^{+})\), and cyclic
permutations. $T_{vvv}^{ev1}$ and $T_{vvv}^{ev2}$ are evanescent, i.e. zero for all helicity configurations in four dimensions. This can be made manifest by rewriting them as

$$
T_{vvv}^{ev1} = \frac{1}{2} k_1^{[\alpha} F_{2}^{\mu \nu} F_{3}^{\sigma \rho]} k_{2 \alpha} F_{4 \mu \nu} F_{3 \sigma \rho},
$$

$$
T_{vvv}^{ev2} = \frac{1}{2} k_2^{[\alpha} F_{1}^{\mu \nu} F_{3}^{\sigma \rho]} k_{1 \alpha} F_{2 \mu \nu} F_{4 \sigma \rho},
$$

(A.9)

where the anti-symmetrization does not include a symmetry factor.

The two-vector, two-scalar tensors are also nonzero under specific helicity combinations, and are given by

$$
T_{vuss}^{++} = 2(k_3 F_1 F_2 k_4) + 2(k_4 F_1 F_2 k_3) - (k_3 \cdot k_4)(F_1 F_2), \quad T_{vuss}^{++} = -(F_1 F_2), \quad (A.10)
$$

where the $v$ and $s$ labels specify the corresponding legs are vectors or scalars.

Similarly, the two-vector, two-fermion tensors are linear combinations of those in Ref. [31], chosen to again be nonzero only under specific helicities:

$$
T_{ffv}^{++} = -\frac{1}{24} (\bar{u}_2 F_1 \bar{F}_2) \bar{k}_3 k_2 u_1, \quad T_{ffv}^{+-} = -\frac{1}{24} (\bar{u}_2 F_1 \bar{F}_2) k_3 k_2 u_1,
$$

$$
T_{ffv}^{--} = -\frac{1}{24} (\bar{u}_2 F_3 \bar{F}_1) k_4 u_1, \quad T_{ffv}^{-+} = -\frac{1}{24} (\bar{u}_2 F_3 \bar{F}_1) k_4 u_1,
$$

$$
T_{ffv}^{\gamma} = \frac{1}{2} k_1^{[\alpha} F_{3}^{\mu \nu} F_{4}^{\sigma \rho]} (\bar{u}_2 \gamma_{\alpha} \gamma_{\mu} \gamma_{\nu} \gamma_{\rho} \gamma_{\sigma} u_1), \quad (A.11)
$$

where $f$ now indicates a leg as a fermion, $F_i = F_{i \mu \nu} \gamma^\mu \gamma^\nu$, and the antisymmetrization in $T^{ev}$ includes a symmetry factor of $1/5!$. As for the four-vector case, we encounter an evanescent tensor, $T_{ffv}^{ev}$ which vanishes for all four-dimensional helicities. For the two-fermion two-scalar case there is only a single basis tensor:

$$
T_{ffs} = \bar{u}_2 \bar{k}_3 u_1. \quad (A.12)
$$

Finally, the four-fermion tensors are,

$$
T_{ffff}^{1} = (\bar{u}_2 \gamma^\mu u_1)(\bar{u}_4 \gamma_\mu u_3),
$$

$$
T_{ffff}^{2} = (\bar{u}_2 \bar{k}_4 u_1)(\bar{u}_4 \bar{k}_2 u_3),
$$

$$
T_{ffff}^{3} = (\bar{u}_2 \gamma^\mu \gamma^\nu \gamma_\rho u_1)(\bar{u}_4 \gamma_\mu \gamma_\nu \gamma_\rho u_3) - 16(\bar{u}_2 \gamma^\mu u_1)(\bar{u}_4 \gamma_\mu u_3),
$$

$$
T_{ffff}^{4} = t (\bar{u}_2 \gamma^\mu \bar{k}_4 \gamma_\rho u_1)(\bar{u}_4 \gamma_\mu \bar{k}_2 \gamma_\rho u_3) - 4t(\bar{u}_2 \bar{k}_4 u_1)(\bar{u}_4 \bar{k}_2 u_3), \quad (A.13)
$$

plus those given by the exchange of legs 2 and 4. It should be noted, however, that in practice it is unnecessary to calculate the coefficients of the exchanged tensors, since they are fixed by the symmetry of the contributing diagrams. $T_{ffff}^{3}$ and $T_{ffff}^{4}$ are chosen to be zero for the helicity configuration $1^+2^-3^+4^-$ and its conjugate, so that these tensors are evanescent if the spinors are Weyl of the same handedness.
B Tree-level and one-loop amplitudes

In this appendix we collect tree- and one-loop amplitudes. In addition to the spinor-helicity amplitudes given below, expressions that are valid to all orders in the dimensional regularization parameter $\epsilon$ are provided in a supplementary file [34]. While we do not require one-loop amplitudes without higher-dimension operators for our specific examples in Section 4, they would be required for the calculation of a generic two-loop anomalous dimension matrix element. These one-loop dimension-4 amplitudes can be found in various references; e.g. Refs. [54] gives the relevant amplitudes which exclude scalars.

The amplitudes and form factors can be written as vectors in color space,

$$A^{(L)}(\lambda_1 \lambda_2 \lambda_3 \lambda_4) = S_{\lambda_1 \lambda_2 \lambda_3 \lambda_4} \sum_i C^{[i]}_{\lambda_1 \lambda_2 \lambda_3 \lambda_4} A^{(L)}(\lambda_1 \lambda_2 \lambda_3 \lambda_4)[i],$$  \hspace{1cm} (B.1)

where $S_{\lambda_1 \lambda_2 \lambda_3 \lambda_4}$ is a helicity-dependent factor which which depending on spinors when evaluated using four-dimensional spinor helicity. These factors are pure phases for the amplitudes with an even number of pairs of external fermions, and for the amplitudes with an odd number of fermions their square is a dimensionless ratio of $s, t, u$ and powers thereof. The full list of $S_{\lambda_1 \lambda_2 \lambda_3 \lambda_4}$ for each process is listed below.

The IR dependence has been stripped from the amplitudes below, but can be reconstructed, if desired, using the basic IR formulas given in the text, which we reproduce here:

$$A^{(1)}_i = I^{(1)} A^{(0)}_i + A^{(1)\text{fin}}_i,$$ \hspace{1cm} (B.2)

where the IR operator $I^{(1)}$ is given by

$$I^{(1)} = \frac{e^{-\epsilon \gamma_E}}{\Gamma(1 - \epsilon)} \sum_{p=1}^{n} \sum_{q \neq p} \frac{T_p \cdot T_q}{2} \left[ \frac{\gamma^{\text{IR}(1)}_{\text{cusp}}}{\epsilon^2} - \frac{\gamma^{\text{IR}(1)}_{c,p}}{T_p^2} \right] \left( \frac{-\mu^2}{2k_p \cdot k_q} \right)^\epsilon,$$ \hspace{1cm} (B.3)

with

$$\gamma^{\text{IR}(1)}_{\text{cusp}} = g^2 4, \hspace{0.5cm} \gamma^{\text{IR}(1)}_{c,v} = -\tilde{g}^2 b_0, \hspace{0.5cm} \gamma^{\text{IR}(1)}_{c,f} = -\tilde{g}^2 3C_F, \hspace{0.5cm} \gamma^{\text{IR}(1)}_{c,s} = -\tilde{g}^2 4C_F.$$ \hspace{1cm} (B.4)

Explicit evaluations of $I^{(1)}$ for various processes can be found, for example, in Refs. [31, 48]. All results below are reported in the Euclidean region and the $\overline{\text{MS}}$ scheme. As a shorthand, logarithms are given by:

$$X^2 = \log \left( \frac{s}{t} \right)^2 + \pi^2, \hspace{1cm} Y^2 = \log \left( \frac{s}{u} \right)^2 + \pi^2, \hspace{1cm} Z^2 = \log \left( \frac{u}{t} \right)^2 + \pi^2,$$

$$X_s = \log \left( \frac{\mu^2}{-s} \right), \hspace{1cm} X_t = \log \left( \frac{\mu^2}{-t} \right), \hspace{1cm} X_u = \log \left( \frac{\mu^2}{-u} \right).$$ \hspace{1cm} (B.5)
In general we drop the Wilson coefficients, for example $c_{F^3}$ for amplitudes with an $O_{F^3}$ insertion, since it is in this form that the amplitudes are used in Eq. (2.37). However we have contracted the Wilson coefficients with the amplitudes for operators which include fermions, since doing so simplifies the flavor information for these cases.

**B.1 Four-vector amplitudes**

The color factors for the four-vector amplitudes are

\[
C_{vvvv}^{[1]} = \text{Tr}[T^1 T^2 T^3 T^4], \quad C_{vvvv}^{[2]} = \text{Tr}[T^1 T^2 T^4 T^3],
\]

\[
C_{vvvv}^{[3]} = \text{Tr}[T^1 T^2 T^3 T^2], \quad C_{vvvv}^{[4]} = \text{Tr}[T^1 T^4 T^2 T^3],
\]

\[
C_{vvvv}^{[5]} = \text{Tr}[T^1 T^3 T^4 T^2], \quad C_{vvvv}^{[6]} = \text{Tr}[T^1 T^4 T^3 T^2],
\]

\[
C_{vvvv}^{[7]} = \text{Tr}[T^1 T^2] \text{Tr}[T^3 T^4], \quad C_{vvvv}^{[8]} = \text{Tr}[T^1 T^3] \text{Tr}[T^2 T^4], \quad C_{vvvv}^{[9]} = \text{Tr}[T^1 T^4] \text{Tr}[T^2 T^3],
\]

where only two partial amplitudes—one single-trace and one double-trace—are independent in general, and the rest are given by relabelings.

We remove dimensionless prefactors from the helicity amplitudes. These are all phases except for the amplitudes involving only one pair of fermions. For the four-vector amplitudes, the spinor prefactors are given by

\[
S(1^+2^+3^+4^+) = \frac{[12][34]}{(12)(34)}, \quad S(1^-2^+3^+4^+) = \frac{\langle 12\rangle\langle 14\rangle\langle 24\rangle}{\langle 23\rangle\langle 24\rangle\langle 34\rangle},
\]

\[
S(1^-2^-3^+4^+) = \frac{\langle 12\rangle\langle 34\rangle}{\langle 34\rangle\langle 12\rangle}, \quad S(1^-2^+3^-4^+) = \frac{\langle 13\rangle\langle 24\rangle}{\langle 24\rangle\langle 13\rangle}. \quad \tag{B.7}
\]

The tree-level $D$-dimensional amplitudes are given by

\[
A^{(0)}(1234)_{[1]} = \frac{-g^2}{st} T_{vvvv}^{\text{tree}},
\]

\[
A^{(0)}(1234)_{[7]} = 0,
\]

\[
A^{(0)}_{F^3}(1234)_{[1]} = \frac{g}{2stu} \left( 4stu T_{vvvv}^{+++} - 2u T_{vvvv}^{-+++} + (s-t) T_{vvvv}^{e2} \right),
\]

\[
A^{(0)}_{F^3}(1234)_{[7]} = 0, \quad \tag{B.8}
\]

which have four-dimensional helicity values

\[
A^{(0)}(1^-2^+3^+4^+)_{[1]} = A^{(0)}(1^=-2^+3^+4^+)_{[1]} = 0,
\]

\[
A^{(0)}(1^-2^-3^+4^+)_{[1]} = \frac{g^2 s}{t},
\]

\[
A^{(0)}(1^-2^+3^-4^+)_{[1]} = \frac{g^2 u^2}{st},
\]

\[
A^{(0)}(1^\pm 2^\pm 3^\pm 4^\pm)_{[7]} = 0, \quad \tag{B.9}
\]
\[
A_{F^3}(1^+2^+3^+4^+)[1] = 2gs,
\]
\[
A_{F^3}(1^-2^+3^+4^+)[1] = -gu,
\]
\[
A_{F^3}(1^-2^+3^-4^+)[1] = A_{F^3}(1^-2^+3^-4^+)[0],
\]
\[
A_{F^3}(1^\pm2^+3^\pm4^\pm)[7] = 0.
\] (B.10)

The one-loop amplitudes with one insertion of the $F^3$ operator are
\[
A_{F^3}^{(1)\text{fin}}(1^+2^+3^+4^+)[1] = g\bar{g}^2((4N(t - u) + 2ub_0)X_s + (4N(s - u) + 2ub_0)X_t
\]
\[
- \frac{1}{2}(44N + 2N_f - N_s)u),
\]
\[
A_{F^3}^{(1)\text{fin}}(1^-2^+3^+4^+)[1] = g\bar{g}^2(N\frac{u^2 - st}{u}X^2
\]
\[
+ (2N(t - u) + b_0u)X_s + (2N(s - u) + b_0u)X_t - 12u),
\]
\[
A_{F^3}(1^-2^+3^-4^+)[1] = 0,
\]
\[
A_{F^3}(1^\pm2^+3^\pm4^\pm)[7] = \frac{g\bar{g}^2}{6}(4N(u - s) - (2N_f - N_s)(u - t)),
\] (B.11)

where $\bar{g}^2 = g^2/(4\pi)$ as defined in Eq.(2.5), and $b_0 = (11N - 2N_f - N_s/2)/3$. The double-trace amplitudes with an $O_{F^3}$ insertion are given by the $U(1)$ decoupling identity
\[
A_{F^3}^{(1)}(1234)[7] = \frac{1}{N} \left( A_{F^3}^{(1)}(1234)[1] + A_{F^3}^{(1)}(1243)[1] + A_{F^3}^{(1)}(1423)[1] \right). \] (B.12)

The amplitudes with one insertion of a $\varphi^2F^2$ operators are
\[
A_{(\varphi^2F^2)_1}^{(1)}(1^\pm2^+3^\pm4^\pm)[1] = 0,
\]
\[
A_{(\varphi^2F^2)_1}^{(1)}(1^+2^+3^+4^+)[7] = g\bar{g}^2N_s s,
\]
\[
A_{(\varphi^2F^2)_1}^{(1)}(1^-2^+3^+4^+)[7] = A_{(\varphi^2F^2)_1}^{(1)}(1^-2^+3^-4^+)[7] = 0,
\]
\[
A_{(\varphi^2F^2)_1}^{(1)}(1^-2^-3^+4^+)[7] = g\bar{g}^2N_s s,
\]
\[
A_{(\varphi^2F^2)_2}^{(1)}(1^\pm2^+3^\pm4^\pm)[1] = -g\bar{g}^2N_s u,
\]
\[
A_{(\varphi^2F^2)_2}^{(1)}(1^\pm2^+3^\pm4^\pm)[7] = A_{(\varphi^2F^2)_2}^{(1)}(1^-2^+3^-4^+)[1] = 0,
\]
\[
A_{(\varphi^2F^2)_2}^{(1)}(1^-2^-3^+4^+)[1] = 2g\bar{g}^2N_s s,
\]
\[
A_{(\varphi^2F^2)_2}^{(1)}(1^-2^-3^+4^+)[7] = A_{(\varphi^2F^2)_2}^{(1)}(1^-2^-3^-4^+)[7] = \frac{4g\bar{g}^2N_s s}{N},
\]
\[
A_{(\varphi^2F^2)_2}^{(1)}(1^-2^+3^+4^+)[7] = A_{(\varphi^2F^2)_2}^{(1)}(1^-2^-3^+4^+)[7] = 0. \] (B.13)

### B.2 Four-fermion amplitudes

The color structures for the four-fermion amplitudes are
\[
C_{ffff}^{[1]} = T_{i_{2i1}}^a T_{i_{4i3}}^a, \quad C_{ffff}^{[2]} = T_{i_{1i1}}^a T_{i_{2i3}}^a. \] (B.14)
Note for any operator, due to the anti-symmetry of the amplitudes under exchange of (anti-)fermions:

\[
A^{(L)}_{\psi}(1^+ 2^- 3^+ 4^-)_{(\psi)} [2] = -A^{(L)}_{\psi}(1^+ 2^- 3^+ 4^-)_{(\overline{\psi})} [1] (s \leftrightarrow t), \\
A^{(L)}_{\psi}(1^+ 2^- 3^- 4^+)_{(\psi)} [2] = -A^{(L)}_{\psi}(1^+ 2^- 3^- 4^+)_{(\overline{\psi})} [1] (s \leftrightarrow t), \\
A^{(L)}_{\psi}(1^+ 2^+ 3^- 4^-)_{(\psi)} [2] = -A^{(L)}_{\psi}(1^+ 2^+ 3^- 4^-)_{(\overline{\psi})} [1] (s \leftrightarrow t). 
\]

(B.15)

The overall spinor phases are

\[
S(1^+ 2^- 3^+ 4^-)_{(\psi)} = \frac{\langle 24 \rangle_{[2]} \langle 34 \rangle_{[24]}}{\langle 34 \rangle_{[23]}}, \quad S(1^+ 2^- 3^+ 4^-)_{(\overline{\psi})} = \frac{\langle 23 \rangle_{[12]} \langle 34 \rangle_{[24]}}{\langle 34 \rangle_{[23]}}, \\
S(1^+ 2^+ 3^- 4^-)_{(\psi)} = \frac{\langle 12 \rangle_{[1]} \langle 34 \rangle_{[24]}}{\langle 34 \rangle_{[23]}}. 
\]

(B.16)

The tree-level \(D\)-dimensional amplitudes are given by

\[
A^{(0)}(1^+ \psi, 2^- \overline{\psi}, 3^+ \psi, 4^- \psi, [1]) = \frac{g^2 u_2 \gamma^\mu \gamma^\nu u_1}{2 s} \overline{u}_4 \gamma_\mu u_3 \delta_{mn} \delta_{\nu \rho}, \\
A^{(0)}_{(\psi)}(1^+ \psi, 2^- \overline{\psi}, 3^+ \psi, 4^- \psi, [1]) = \frac{N}{N^2 - 1} \left( c_{(\psi)}^{nm} u_2 \gamma^\mu u_1 \overline{u}_n \gamma_\mu u_3 - c_{(\overline{\psi})}^{nm} u_4 \gamma_\mu u_1 \overline{u}_n \gamma_\mu u_3 \right), \\
A^{(0)}_{(\psi)}(1^+ \psi, 2^- \overline{\psi}, 3^- \psi, 4^- \psi, [1]) = c_{(\psi)}^{nm} u_2 \gamma^\mu u_1 \overline{u}_n \gamma_\mu u_3 . 
\]

(B.17)

which have four-dimensional values

\[
A^{(0)}(1^+ \psi, 2^- \overline{\psi}, 3^+ \psi, 4^- \psi, [1]) = \frac{g^2 u_2}{s} \delta_{mn} \delta_{\nu \rho}, \\
A^{(0)}(1^+ \psi, 2^- \overline{\psi}, 3^- \psi, 4^- \psi, [1]) = -\frac{g^2 t}{s} \delta_{mn} \delta_{\nu \rho}, \\
A^{(0)}(1^+ \psi, 2^+ \overline{\psi}, 3^+ \psi, 4^- \psi, [1]) = 0, \\
A^{(0)}_{(\psi)}(1^+ \psi, 2^- \overline{\psi}, 3^+ \psi, 4^- \psi, [1]) = -\frac{2 Nu(N c_{(\psi)}^{nm} + c_{(\overline{\psi})}^{nm})}{N^2 - 1}, \\
A^{(0)}_{(\psi)}(1^+ \psi, 2^- \overline{\psi}, 3^- \psi, 4^- \psi, [1]) = \frac{2 N t c_{(\psi)}^{nm}}{N^2 - 1}, \\
A^{(0)}_{(\psi)}(1^+ \psi, 2^+ \overline{\psi}, 3^- \psi, 4^- \psi, [1]) = \frac{2 N^2 s c_{(\overline{\psi})}^{nm}}{N^2 - 1}, \\
A^{(0)}_{(\psi)}(1^+ \psi, 2^- \overline{\psi}, 3^+ \psi, 4^- \psi, [1]) = 0. 
\]

(B.18)
The amplitudes with one insertion of the $F^3$ operator are

$$A^{(1)}_{F^3}(1^+_{\psi_m} 2^-_{\psi_n} 3^+_{\psi_p} 4^-_{\psi_r})[1] = \frac{1}{3} \tilde{g}^2 u \delta_{mn} \delta_{pr},$$

$$A^{(1)}_{F^3}(1^+_{\psi_m} 2^-_{\psi_n} 3^-_{\psi_p} 4^+_{\psi_r})[1] = -\frac{1}{3} \tilde{g}^2 t \delta_{mn} \delta_{pr},$$

$$A^{(1)}_{F^3}(1^+_{\psi_m} 2^-_{\psi_n} 3^-_{\psi_p} 4^-_{\psi_r})[1] = 0 .$$

(B.19)

The amplitudes with one insertion of a $D\varphi^2 \psi^2$ operator are

$$A^{(1)}_{(D\varphi^2 \psi^2)_1}(1^+_{\psi_m} 2^-_{\psi_n} 3^+_{\psi_p} 4^-_{\psi_r})[1] = 0 ,$$

$$A^{(1)}_{(D\varphi^2 \psi^2)_2}(1^+_{\psi_m} 2^-_{\psi_n} 3^+_{\psi_p} 4^-_{\psi_r})[1] = -\frac{1}{9} \tilde{g}^2 N_s (3X_s + 8) u (c_{(D\varphi^2 \psi^2)_2}^{r_{rpm}} \delta_{mn} + c_{(D\varphi^2 \psi^2)_2}^{n_{rpm}} \delta_{pr}),$$

$$A^{(1)}_{(D\varphi^2 \psi^2)_2}(1^+_{\psi_m} 2^-_{\psi_n} 3^-_{\psi_p} 4^+_{\psi_r})[1] = \frac{1}{9} \tilde{g}^2 N_s (3X_s + 8) t (c_{(D\varphi^2 \psi^2)_2}^{r_{rpm}} \delta_{mn} + c_{(D\varphi^2 \psi^2)_2}^{n_{rpm}} \delta_{pr}),$$

$$A^{(1)}_{(D\varphi^2 \psi^2)_2}(1^+_{\psi_m} 2^-_{\psi_n} 3^-_{\psi_p} 4^-_{\psi_r})[1] = 0 .$$

(B.20)

The amplitudes with one insertion of a $\psi^4$ operator are

$$A^{(1)\text{fin}}_{(\psi^4)_1}(1^+_{\psi_m} 2^-_{\psi_n} 3^+_{\psi_p} 4^-_{\psi_r})[1] = \frac{2\tilde{g}^2 u}{9Nst} \left( t (72Nc_{(\psi^4)_1}^{r_{rpm}}) 
+ N_f (3X_s + 2) (\delta_{mn} c_{(\psi^4)_1}^{r_{rpm}} + \delta_{pr} c_{(\psi^4)_1}^{n_{rpm}}) 
+ 9 (2s + t (3X_u + 25)) c_{(\psi^4)_1}^{n_{rpm}} \right),$$

$$A^{(1)\text{fin}}_{(\psi^4)_1}(1^+_{\psi_m} 2^-_{\psi_n} 3^-_{\psi_p} 4^+_{\psi_r})[1] = -\frac{2}{9} \tilde{g}^2 N_s (3X_s + 2) (\delta_{mn} c_{(\psi^4)_1}^{r_{rpm}} + \delta_{pr} c_{(\psi^4)_1}^{n_{rpm}}) 
+ 9 (2s + t (5 - 3X_l)) c_{(\psi^4)_1}^{n_{rpm}},$$

$$A^{(1)\text{fin}}_{(\psi^4)_1}(1^+_{\psi_m} 2^-_{\psi_n} 3^-_{\psi_p} 4^-_{\psi_r})[1] = -16\tilde{g}^2 N s c_{(\psi^4)_1}^{n_{rpm}} ,$$

$$A^{(1)\text{fin}}_{(\psi^4)_2}(1^+_{\psi_m} 2^-_{\psi_n} 3^+_{\psi_p} 4^-_{\psi_r})[1] = \frac{2\tilde{g}^2 u}{9Ns} \left( 9 s \left( 2 (N^2 - 1) s + t (13N^2 - 3X_u - 25) \right) c_{(\psi^4)_2}^{n_{rpm}} 
+ t (N_f s (2N (3X_s + 5) (\delta_{mn} c_{(\psi^4)_2}^{r_{rpm}} + \delta_{pr} c_{(\psi^4)_2}^{n_{rpm}}) 
- (3X_s + 2) (\delta_{mn} c_{(\psi^4)_2}^{r_{rpm}} + \delta_{pr} c_{(\psi^4)_2}^{n_{rpm}}) 
+ 9 N s (3X_u + 17) + 2 t) c_{(\psi^4)_2}^{n_{rpm}} \right),$$

$$A^{(1)\text{fin}}_{(\psi^4)_2}(1^+_{\psi_m} 2^-_{\psi_n} 3^-_{\psi_p} 4^+_{\psi_r})[1] = -\frac{2\tilde{g}^2}{9N} \left( 9 \left( 2 (N^2 - 1) s - t (3 (N^2 - 1) X_t - 3N^2 + 5) \right) c_{(\psi^4)_2}^{n_{rpm}} 
+ N_f t (2N (3X_s + 5) (\delta_{mn} c_{(\psi^4)_2}^{r_{rpm}} + \delta_{pr} c_{(\psi^4)_2}^{n_{rpm}}) 
- (3X_s + 2) (\delta_{mn} c_{(\psi^4)_2}^{r_{rpm}} + \delta_{pr} c_{(\psi^4)_2}^{n_{rpm}}) \right),$$

$$A^{(1)\text{fin}}_{(\psi^4)_2}(1^+_{\psi_m} 2^-_{\psi_n} 3^-_{\psi_p} 4^-_{\psi_r})[1] = 2\tilde{g}^2 (3s (X_s + 1) - 2 t) c_{(\psi^4)_2}^{n_{rpm}} .$$

(B.21)
B.3 Four-scalar amplitudes

The color structures for this process are identical to those of the four fermion case:

\[ C_{ssss}^{[1]} = T_{i_1i_2}^a T_{i_3i_4}^a, \quad C_{ssss}^{[2]} = T_{i_1i_2}^a T_{i_3i_4}^a. \] (B.22)

There is no spinor phase in this case, as the scalars do not carry helicity weight. The tree-level amplitudes are

\[ A^{(0)}_{(1ϕ_2ϕ_3ϕ_4)}[1] = -\frac{g^2(t - u)}{2s} - \frac{2\lambda N}{N - 1}, \]
\[ A^{(0)}_{(D^2ϕ^4)_1}(1ϕ_2ϕ_3ϕ_4)[1] = \frac{N(NT + s)}{N^2 - 1}, \]
\[ A^{(0)}_{(D^2ϕ^4)_2}(1ϕ_2ϕ_3ϕ_4)[1] = \frac{2N(NT + s)}{N^2 - 1}. \] (B.23)

The one-loop amplitudes with an insertion of the \( F^3 \) operator are

\[ A^{(1)}_{F^3}(1ϕ_2ϕ_3ϕ_4)[1] = -\frac{1}{6}g\tilde{g}^2NT(t - u). \] (B.24)

The one-loop amplitudes with an insertion of a \( ϕ^2F^2 \) operator are

\[ A^{(1)}_{(ϕ^2F^2)_1}(1ϕ_2ϕ_3ϕ_4)[1] = 2\tilde{g}^2(NT + s), \]
\[ A^{(1)}_{(ϕ^2F^2)_2}(1ϕ_2ϕ_3ϕ_4)[1] = \frac{2\tilde{g}^2(N^2 - 4)s}{N}. \] (B.25)

The one-loop amplitudes with an insertion of a \( D^2ϕ^4 \) operator are

\[ A^{(1)\text{fin}}_{(D^2ϕ^4)_1}(1ϕ_2ϕ_3ϕ_4)[1] = \frac{\tilde{g}^2}{2}\left(-4(4N + 3)s - 2(3N + 5)t \right. \]
\[ - 3(N - 2)tX_t - 3sX_s + 3uX_u \]
\[ + \frac{2\lambda}{N - 1}\left(2N((N - 3)t - 2s) - NsX_s \right. \]
\[ + (N - 2)NtX_t + NuX_u \right), \]
\[ A^{(1)\text{fin}}_{(D^2ϕ^4)_2}(1ϕ_2ϕ_3ϕ_4)[1] = \frac{\tilde{g}^2}{9}\left(-2(2t(9N + 4Ns + 27) + (4Ns + 45)s) \right. \]
\[ + 27(2N - 1)tX_t - 3X_s((Ns - 18)s + 2Nst) + 27uX_u \]
\[ + \frac{4\lambda N}{N - 1}\left(-4(NT + s) + (1 - 2N)tX_t - sX_s + uX_u \right). \] (B.26)

The one-loop amplitudes with an insertion of a \( Dϕ^2ψ^2 \) operator are

\[ A^{(1)}_{(Dϕ^2ψ^2)_1}(1ϕ_2ϕ_3ϕ_4)[1] = 0, \]
\[ A^{(1)}_{(Dϕ^2ψ^2)_2}(1ϕ_2ϕ_3ϕ_4)[1] = -\frac{2}{9}c_{(Dϕ^2ψ^2)_2}^{ww}\tilde{g}^2(3X_s + 5)(t - u). \] (B.27)
B.4 Two-fermion, two-vector amplitudes

The color factors for the two-fermion, two-vector amplitudes are

\[ C_{ffvv}^{[1]} = (T^3T^4)_{i_2i_1}, \quad C_{ffvv}^{[2]} = (T^4T^3)_{i_2i_1}, \quad C_{ffvv}^{[3]} = \text{Tr}[T^3T^4] \delta_{i_2i_1}. \] (B.28)

In this case the spinor prefactors are not pure phases, but have magnitudes equal to ratios of \(s, t,\) and \(u:\)

\[
S(1^{-} 2^{+}\, 3^{+} 4^{+}) = \frac{\langle 13 \rangle \langle 34 \rangle}{\langle 23 \rangle \langle 34 \rangle}, \quad S(1^{-} 2^{+}\, 3^{-} 4^{+}) = \frac{\langle 13 \rangle}{\langle 12 \rangle \langle 34 \rangle \langle 41 \rangle},
\]

\[
S(1^{-} 2^{+}\, 3^{+} 4^{-}) = \frac{\langle 14 \rangle^3}{\langle 12 \rangle \langle 31 \rangle \langle 43 \rangle}, \quad S(1^{-} 2^{+}\, 3^{-} 4^{-}) = \frac{\langle 34 \rangle^3}{\langle 23 \rangle \langle 24 \rangle \langle 12 \rangle}. \] (B.29)

The tree-level amplitudes for this process are

\[
A_0^{(0)}(1^{-} 2^{+}\, 34)[1] = -\frac{g^2}{s t} (2T_{ffvv}^{+++} - 2T_{ffvv}^{+++} + T_{ffvv}^{ev}) \delta_{pr},
\]

\[
A_F^{(0)}(1^{-} 2^{+}\, 34)[1] = -\frac{2g}{s} (T_{ffvv}^{+++} + T_{ffvv}^{+++}) \delta_{pr}, \] (B.30)

which evaluate in four dimensions as

\[
A_0^{(0)}(1^{-} 2^{+}\, 34)[1] = 0,
\]

\[
A_0^{(0)}(1^{-} 2^{+}\, 34)[1] = g^2 \delta_{pr},
\]

\[
A_0^{(0)}(1^{-} 2^{+}\, 34)[1] = \frac{g^2 t}{u} \delta_{pr},
\]

\[
A_0^{(0)}(1^{-} 2^{+}\, 34)[1] = 0,
\]

\[
A_F^{(0)}(1^{-} 2^{+}\, 34)[1] = -gt \delta_{pr},
\]

\[
A_F^{(0)}(1^{-} 2^{+}\, 34)[1] = 0,
\]

\[
A_F^{(0)}(1^{-} 2^{+}\, 34)[1] = 0,
\]

\[
A_F^{(0)}(1^{-} 2^{+}\, 34)[1] = \frac{gt}{s} \delta_{pr}. \] (B.31)

The one-loop amplitudes with an insertion of a \(F^3\) operator are

\[
A^{(1)\text{fin}}_F(1^{-} 2^{+}\, 34)[1] = \frac{g^2 \delta_{pr}}{8N^2} \left( 2tu(34N^2 + N(5N_f + 2N_s) - 18) + 9Ntu((4N_f + N_s)X_s + 2(N - b_0)X_t) + 18N^2(t - u)tX^2 \right),
\]

\[
A^{(1)\text{fin}}_F(1^{-} 2^{+}\, 34)[1] = 0,
\]

\[
A^{(1)\text{fin}}_F(1^{-} 2^{+}\, 34)[1] = g^2 \delta_{pr} N \frac{stu}{t},
\]

\[
A^{(1)\text{fin}}_F(1^{-} 2^{+}\, 34)[1] = -\frac{u}{s} A^{(1)\text{fin}}_F(1^{-} 2^{+}\, 34)[1]. \] (B.32)
The one-loop amplitudes with an insertion of a \(\bar{\psi} \psi\) operator all evaluate to zero:

\[
A^{(1)}_{(\varphi^2 F^2)}(1 \psi_p \psi_r \varphi^c T \varphi^c r)^{[1]}[1] = A^{(1)}_{(\varphi^2 F^2)}(1 \psi_p \psi_r \varphi^c 4 \varphi^c 4)^{[3]}[3] = 0 ,
\]

\[
A^{(1)}_{(\varphi^2 F^2)}(1 \psi_p \psi_r \varphi^c 2 \varphi^c 4)^{[1]}[1] = A^{(1)}_{(\varphi^2 F^2)}(1 \psi_p \psi_r \varphi^c 2 \varphi^c 4)^{[3]}[3] = 0 .
\]

The one-loop amplitudes with an insertion of a \(D \bar{\psi} \psi^2\) operator are

\[
A^{(1)}_{(D \bar{\psi} \psi^2)}(1 \psi_p \psi_r \varphi^c T \varphi^c r)^{[1]}[1] = A^{(1)}_{(D \bar{\psi} \psi^2)}(1 \psi_p \psi_r \varphi^c 4 \varphi^c 4)^{[3]}[3] = 0 ,
\]

\[
A^{(1)}_{(D \bar{\psi} \psi^2)}(1 \psi_p \psi_r \varphi^c 2 \varphi^c 4)^{[1]}[1] = A^{(1)}_{(D \bar{\psi} \psi^2)}(1 \psi_p \psi_r \varphi^c 2 \varphi^c 4)^{[3]}[3] = 0 .
\]

The one-loop amplitudes with an insertion of a \(\bar{\psi} \psi^4\) operator are

\[
A^{(1)}_{(\bar{\psi} \psi^4)}(1 \psi_p \psi_r \varphi^c T \varphi^c r)^{[1]}[1] = A^{(1)}_{(\bar{\psi} \psi^4)}(1 \psi_p \psi_r \varphi^c 4 \varphi^c 4)^{[3]}[3] = 0 ,
\]

\[
A^{(1)}_{(\bar{\psi} \psi^4)}(1 \psi_p \psi_r \varphi^c 2 \varphi^c 4)^{[1]}[1] = A^{(1)}_{(\bar{\psi} \psi^4)}(1 \psi_p \psi_r \varphi^c 2 \varphi^c 4)^{[3]}[3] = 0 .
\]

B.5 Two-scalar, two-vector amplitudes

The color basis for this process is analogous to the that of the previous:

\[
C^{[1]}_{\varphi \varphi} = (T^1 T^2)_{\varphi \varphi}^{\varphi \varphi} , \quad C^{[2]}_{\varphi \varphi} = (T^2 T^1)_{\varphi \varphi}^{\varphi \varphi} , \quad C^{[3]}_{\varphi \varphi} = \text{Tr}[T^{i} T^{j}]_{\varphi \varphi}^{\varphi \varphi} \delta_{\varphi \varphi}^{\varphi \varphi} .
\]

The spinor factors are again pure phases:

\[
B_{\text{spin}} = \frac{12}{(12)} , \quad S(1^+ 2^+ 3^+ 4^-) = \frac{23}{(23)(24)[12][34]} , \quad S(1^+ 2^- 3^+ 4^+) = \frac{23}{(12)(34)[23][24]} .
\]
The $D$-dimensional tree-level expressions are given by

\begin{align*}
A^{(1)}(123\phi^4\phi)[1] &= -\frac{g^2}{s t} T^{++}_{\text{vess}}, \\
A^{(1)}(123\phi^4\phi)[3] &= 0, \\
A^{(1)}_{F_3}(123\phi^4\phi)[1] &= \frac{g(t - u)}{2s} T^{++}_{\text{vess}}, \\
A^{(1)}_{F_3}(123\phi^4\phi)[3] &= 0, \\
A^{(1)}_{(\phi^2 F^2)_1}(123\phi^4\phi)[1] &= 0, \\
A^{(1)}_{(\phi^2 F^2)_1}(123\phi^4\phi)[3] &= -2T^{++}_{\text{vess}}, \\
A^{(1)}_{(\phi^2 F^2)_2}(123\phi^4\phi)[1] &= -2T^{++}_{\text{vess}}, \\
A^{(1)}_{(\phi^2 F^2)_2}(123\phi^4\phi)[3] &= -\frac{4}{N} T^{++}_{\text{vess}},
\end{align*}

(B.39)

with four-dimensional helicity values

\begin{align*}
A^{(1)}(1^+2^+3^-4^+\phi)[1] &= 0, \\
A^{(1)}(1^+2^-3^-4^+\phi)[1] &= \frac{g^2 u}{s}, \\
A^{(1)}(1^+2^\mp 3^-4^\pm \phi)[3] &= 0, \\
A^{(1)}_{F_3}(1^+2^+3^-4^+\phi)[1] &= \frac{1}{2} g(t - u), \\
A^{(1)}_{F_3}(1^+2^-3^-4^+\phi)[1] &= 0, \\
A^{(1)}_{F_3}(1^+2^\mp 3^-4^\pm \phi)[3] &= 0, \\
A^{(1)}_{(\phi^2 F^2)_1}(1^+2^\pm 3^-4^\mp \phi)[1] &= 0, \\
A^{(1)}_{(\phi^2 F^2)_1}(1^+2^+3^-4^+\phi)[3] &= -2s, \\
A^{(1)}_{(\phi^2 F^2)_1}(1^+2^-3^-4^+\phi)[3] &= 0, \\
A^{(1)}_{(\phi^2 F^2)_2}(1^+2^+3^-4^+\phi)[1] &= -2s, \\
A^{(1)}_{(\phi^2 F^2)_2}(1^+2^-3^-4^+\phi)[1] &= 0, \\
A^{(1)}_{(\phi^2 F^2)_2}(1^+2^\mp 3^-4^\pm \phi)[3] &= -\frac{4s}{N}, \\
A^{(1)}_{(\phi^2 F^2)_2}(1^+2^-3^-4^+\phi)[3] &= 0.
\end{align*}

(B.40)
The one-loop amplitudes with an insertion of the $F^3$ operator are

$$A^{(1)\text{fin}}_{F^3}(1^+2^+3\varphi^4)[1] = -\frac{g g^2}{72 N} \left( 8((52N^2 - 18)s + (77N^2 - 36)t + N(t - u)(5N_f + 2N_s))
\right.
\left. + 18N((2N(5t - 7u) - 3b_0(t - u))X_t + X_s(2Ns + b_0(u - t)))
- 72N^2tX^2 \right),$$

$$A^{(1)}_{F^3}(1^+2^-3\varphi^4)[1] = \frac{1}{2}g g^2 Nu,$$

$$A^{(1)\text{fin}}_{F^3}(1^+2^+3\varphi^4)[3] = \frac{g g^2}{4N} \left( (8Nt + b_0(t - u))X_t + (8Nu + b_0(u - t))X_u - 4NsX_s
\right.
\left. + \frac{1}{6s}(stX^2 + suY^2 + tuZ^2) \right),$$

$$A^{(1)}_{F^3}(1^+2^-3\varphi^4)[3] = -g g^2 s. \quad \text{(B.41)}$$

The one-loop amplitudes with an insertion of a $\varphi^2 F^2$ operator are

$$A^{(1)\text{fin}}_{(\varphi^2 F^2)_1}(1^+2^+3\varphi^4)[1] = -\frac{g g^2}{N}((b_0 - 2N)X_t + b_0X_u) + 4g^2 s, \quad \text{(B.42)}$$

$$A^{(1)}_{(\varphi^2 F^2)_1}(1^+2^-3\varphi^4)[1] = 2g^2(s + 3t),$$

$$A^{(1)\text{fin}}_{(\varphi^2 F^2)_1}(1^+2^+3\varphi^4)[3] = g^2 s \left( 4C_F - 2(b_0 + 3C_F)X_s \right)
+ 4\lambda(N + 1)s(X_s + 2),$$

$$A^{(1)}_{(\varphi^2 F^2)_1}(1^+2^-3\varphi^4)[3] = 0,$$

$$A^{(1)\text{fin}}_{(\varphi^2 F^2)_2}(1^+2^+3\varphi^4)[1] = \frac{g^2 s}{N^2} \left( 6N(2N^2 - 3) + N(3 - Nb_0)X_s + 2b_0X_u
\right.
\left. + (2N(N^2 - 4) - b_0(N^2 - 2))X_t
\right.
\left. + 4\lambda s(X_s + 2) \right),$$

$$A^{(1)}_{(\varphi^2 F^2)_2}(1^+2^-3\varphi^4)[1] = -\frac{2g^2}{N} \left( N^2u + 4t \right),$$

$$A^{(1)\text{fin}}_{(\varphi^2 F^2)_2}(1^+2^+3\varphi^4)[3] = \frac{g^2 s}{N^2} \left( 2(b_0N - 3)X_s + b_0N(X_t + X_u) - 3 \left( 4N^2 - 1 \right)
\right.
\left. - \frac{8}{N}\lambda s(X_s + 2) \right),$$

$$A^{(1)}_{(\varphi^2 F^2)_2}(1^+2^-3\varphi^4)[3] = -4g^2 s. \quad \text{(B.43)}$$
The one-loop amplitudes with an insertion of a $D^2\phi^4$ operator are

\[
A_{(D^2\phi^4)_1}^{(1)}(1^{+2}_3\phi^4_4)[l] = -\frac{1}{2}g^2 N_s s ,
\]

\[
A_{(D^2\phi^4)_1}^{(1)}(1^{+2}_3\phi^4_4)[1] = 0 ,
\]

\[
A_{(D^2\phi^4)_1}^{(1)}(1^{+2}_3\phi^4_4)[3] = -A_{(D^2\phi^4)_1}^{(1)}(1^{+2}_3\phi^4_4)[1] ,
\]

\[
A_{(D^2\phi^4)_2}^{(1)}(1^{+2}_3\phi^4_4)[1] = \frac{1}{3}g^2 N_s (s - t) ,
\]

\[
A_{(D^2\phi^4)_2}^{(1)}(1^{+2}_3\phi^4_4)[1] = 0 ,
\]

\[
A_{(D^2\phi^4)_2}^{(1)}(1^{+2}_3\phi^4_4)[3] = 4A_{(D^2\phi^4)_1}^{(1)}(1^{+2}_3\phi^4_4)[1] .
\] (B.44)

The one-loop amplitudes with an insertion of a $D\phi^2\psi^2$ operator are

\[
A_{(D\phi^2\psi^2)_1}^{(1)}(1^{+2}_3\phi^4_4)[l] = A_{(D\phi^2\psi^2)_1}^{(1)}(1^{+2}_3\phi^4_4)[1] = 0 ,
\]

\[
A_{(D\phi^2\psi^2)_2}^{(1)}(1^{+2}_3\phi^4_4)[1] = \frac{1}{3}g^2 c_{(D\phi^2\psi^2)_2} N_f (t - u) ,
\]

\[
A_{(D\phi^2\psi^2)_2}^{(1)}(1^{+2}_3\phi^4_4)[3] = A_{(D\phi^2\psi^2)_2}^{(1)}(1^{+2}_3\phi^4_4)[3] .
\] (B.45)

**B.6 Two-fermion, two-scalar amplitudes**

The color structures for this process are identical to those of the four fermion case:

\[
C_{ffss}^{[1]} = T_{i_1 i_2}^a T_{i_3 i_4}^a , \quad C_{ffss}^{[2]} = T_{i_1 i_2}^a T_{i_3 i_4}^a . \tag{B.46}
\]

There is only one independent spinor prefactor (which again is not a pure phase for this case):

\[
S(1\psi_2^+ 3\phi^4_4) = \frac{(23)[13]}{s} . \tag{B.47}
\]

The tree-level amplitudes for this process are given by

\[
A^{(0)}(1\psi_2^+ 3\phi^4_4)[1] = g^2 \frac{\bar{u}_2 k_3 u_1}{s} \delta_{pr} ,
\]

\[
A^{(0)}(1\psi_2^+ 3\phi^4_4)[2] = 0 ,
\]

\[
A_{(D\phi^2\psi^2)_1}^{(0)}(1\psi_2^+ 3\phi^4_4)[1] = -2c_{(D\phi^2\psi^2)_1} N(\bar{u}_2 k_3 u_1) \frac{N^2 - 1}{N^2} ,
\]

\[
A_{(D\phi^2\psi^2)_2}^{(0)}(1\psi_2^+ 3\phi^4_4)[1] = -2c_{(D\phi^2\psi^2)_2} N^2 (\bar{u}_2 k_3 u_1) \frac{N^2 - 1}{N^2} ,
\]

\[
A_{(D\phi^2\psi^2)_2}^{(0)}(1\psi_2^+ 3\phi^4_4)[1] = -2c_{(D\phi^2\psi^2)_2} (\bar{u}_2 k_3 u_1) ,
\]

\[
A_{(D\phi^2\psi^2)_2}^{(0)}(1\psi_2^+ 3\phi^4_4)[2] = 0 ,
\]

\[
A_{(D\phi^2\psi^2)_2}^{(0)}(1\psi_2^+ 3\phi^4_4)[2] = 0 , \tag{B.48}
\]
with four-dimensional helicity values

\[ A^{(0)}(1^+ 2^- 3^4 \bar{4})[1] = g^2 \delta_{pr}, \]
\[ A^{(0)}(1^+ 2^- 3^4 \bar{4})[2] = 0, \]
\[ A^{(0)}_{(D^2 \varphi^2)}(1^+ 2^- 3^4 \bar{4})[1] = -\frac{4 \epsilon^{rp}_{(D^2 \varphi^2)} N s}{N^2 - 1}, \]
\[ A^{(0)}_{(D^2 \varphi^2)}(1^+ 2^- 3^4 \bar{4})[2] = -\frac{4 \epsilon^{rp}_{(D^2 \varphi^2)} N^2 s}{N^2 - 1}, \]
\[ A^{(0)}_{(D^2 \varphi^2)}(1^+ 2^- 3^4 \bar{4})[1] = -4 \epsilon^{rp}_{(D^2 \varphi^2)} s, \]
\[ A^{(0)}_{(D^2 \varphi^2)}(1^+ 2^- 3^4 \bar{4})[2] = 0. \]

The one-loop amplitudes with an insertion of the \( F^3 \) operator are

\[ A^{(1)}_{F^3}(1^+ 2^- 3^4 \bar{4})[1] = \frac{1}{6} g g^2 N s \delta_{pr}, \]
\[ A^{(1)}_{F^3}(1^+ 2^- 3^4 \bar{4})[2] = 0. \]

The one-loop amplitudes with an insertion of a \( \varphi^2 F^2 \) operator all evaluate to zero:

\[ A^{(1)}_{(\varphi^2 F^2)}(1^+ 2^- 3^4 \bar{4})[1] = A^{(1)}_{(\varphi^2 F^2)}(1^+ 2^- 3^4 \bar{4})[2] = 0, \]
\[ A^{(1)}_{(\varphi^2 F^2)}(1^+ 2^- 3^4 \bar{4})[1] = A^{(1)}_{(\varphi^2 F^2)}(1^+ 2^- 3^4 \bar{4})[2] = 0. \]

The one-loop amplitudes with an insertion of a \( D^2 \varphi^4 \) operator are

\[ A^{(1)}_{(D^2 \varphi^4)}(1^+ 2^- 3^4 \bar{4})[1] = A^{(1)}_{(D^2 \varphi^4)}(1^+ 2^- 3^4 \bar{4})[2] = 0, \]
\[ A^{(1)}_{(D^2 \varphi^4)}(1^+ 2^- 3^4 \bar{4})[1] = \frac{1}{9} g^2 N s (3 X_t + 8) \delta_{pr}, \]
\[ A^{(1)}_{(D^2 \varphi^4)}(1^+ 2^- 3^4 \bar{4})[2] = 0. \]

The one-loop amplitudes with an insertion of a \( D \varphi^2 \varphi^2 \) operator are

\[ A^{(1)\text{fin}}_{(D \varphi^2 \varphi^2)}(1^+ 2^- 3^4 \bar{4})[1] = -\bar{g}^2 s (3 X_t - 3 X_u - 16) c^{rp}_{(D \varphi^2 \varphi^2)} , \]
\[ A^{(1)\text{fin}}_{(D \varphi^2 \varphi^2)}(1^+ 2^- 3^4 \bar{4})[2] = 16 \bar{g}^2 N s c^{rp}_{(D \varphi^2 \varphi^2)} , \]
\[ A^{(1)\text{fin}}_{(D \varphi^2 \varphi^2)}(1^+ 2^- 3^4 \bar{4})[1] = \frac{\bar{g}^2 s}{9 N} c^{rp}_{(D \varphi^2 \varphi^2)} \left( 8 \left( 9 N^2 + 6 N s - 18 \right) - 27 \left( N^2 - 1 \right) X_t + 3 N N s X_t - 27 X_u \right) \]
\[ + \frac{4}{9} \bar{g}^2 N s (3 X_t + 5) c^{\text{new}}_{(D \varphi^2 \varphi^2)} \delta_{pr}, \]
\[ A^{(1)\text{fin}}_{(D \varphi^2 \varphi^2)}(1^+ 2^- 3^4 \bar{4})[2] = -3 \bar{g}^2 s (X_t - X_u) c^{rp}_{(D \varphi^2 \varphi^2)} . \]
The one-loop amplitudes with an insertion of a $\psi^4$ operator are

\[
A^{(1)}_{(\psi^4)_1} (1^+ \frac{-2\bar{\psi} \gamma_5 3\phi 4\bar{\psi}}{\psi})_{[1]} = -\frac{4\tilde{g}^2}{9} N_f s (3X_s + 2) c^{rwup}_{(\psi^4)_1},
\]

\[
A^{(1)}_{(\psi^4)_1} (1^+ \frac{-2\bar{\psi} \gamma_5 3\phi 4\bar{\psi}}{\psi})_{[2]} = 0,
\]

\[
A^{(1)}_{(\psi^4)_2} (1^+ \frac{-2\bar{\psi} \gamma_5 3\phi 4\bar{\psi}}{\psi})_{[1]} = \frac{2\tilde{g}^2 N_fs}{9N} ((3X_s + 2) c^{rwup}_{(\psi^4)_2} - 2N(3X_s + 5) c^{rwup}_{(\psi^4)_2}),
\]

\[
A^{(1)}_{(\psi^4)_2} (1^+ \frac{-2\bar{\psi} \gamma_5 3\phi 4\bar{\psi}}{\psi})_{[2]} = 0. \quad (B.54)
\]
