Abstract
We analyze algorithmic problems in finitely generated semigroups of two-dimensional upper-triangular integer matrices. These semigroup problems are tightly connected with problems about compositions of affine functions over one variable. Building on a variety of techniques from recent years, we obtain a number of complexity results, including NP-completeness of the mortality problem for matrices with determinants \(+1\) and \(0\).

1 Introduction

A finite set of matrices \(M \subset \mathbb{Q}^{d \times d}\) generates a monoid \(\langle M \rangle\) under matrix multiplication, i.e., \(\langle M \rangle\) is the set of products of matrices from \(M\). The natural algorithmic problems about such monoids are hard, often undecidable. For example, Paterson [17] showed in 1970 that the mortality problem, i.e., deciding whether the zero matrix is in the generated monoid, is undecidable, even in dimension \(d = 3\). It remains undecidable for \(d = 3\) with \(|M| = 7\) and for \(d = 21\) with \(|M| = 2\), see [13]. Mortality for two-dimensional matrices is known to be NP-hard [1], but decidability remains a longstanding open problem, see, e.g., [19].

Mortality is a special case of the membership problem: given \(M\) and a matrix \(T\), is \(T \in \langle M \rangle\)? Two other natural problems consider certain linear projections of the matrices in \(\langle M \rangle\): The vector reachability problem asks, given \(M\) and two vectors \(\vec{x}, \vec{y} \in \mathbb{Q}^d\), if there is a matrix \(M \in \langle M \rangle\) such that \(M \vec{x} = \vec{y}\). Similarly, the scalar reachability problem asks whether there is a matrix \(M \in \langle M \rangle\) such that \(\vec{y}^T M \vec{x} = \lambda\) holds for given vectors \(\vec{x}, \vec{y}\) and a given scalar \(\lambda \in \mathbb{Q}\). None of these problems is known to be decidable, not even for \(d = 2\) and integer matrices. Mortality is known to be decidable when both \(d = 2\) and \(|M| = 2\) hold [5].

Even the case of a single matrix, i.e., \(|M| = 1\), is very difficult, see [16] for a survey. This case is closely related to the algorithmic analysis of linear recurrence sequences, which are sequences \(u_0, u_1, \ldots\) of numbers such that there are constants \(a_1, \ldots, a_d\) such that \(u_{n+d} = a_1u_{n+d-1} + a_2u_{n+d-2} + \cdots + a_d u_n\) holds for all \(n \in \mathbb{N}\). In the case \(|M| = 1\) the vector reachability problem is referred to as orbit problem, and the scalar reachability problem as Skolem problem. The orbit problem is decidable in polynomial time [14], but the Skolem problem is only known to be decidable for \(d \leq 4\) (this requires Baker’s Theorem), see [15, 5].

In the following we do not restrict \(|M|\) but focus on integer matrices in \(d = 2\). Recently, there has been steady progress for certain special cases. It was shown by Potapov and Semukhin [19] that the membership problem for two-dimensional integer matrices is decidable for non-singular matrices. This result builds on automata-theoretic techniques developed,
On Semigroups of Two-Dimensional Upper-Triangular Integer Matrices

e.g., in [7], where it was shown that the problem of deciding whether $\langle \mathcal{M} \rangle$ is a group is decidable. At its heart, this technique exploits special structures of the group of matrices with determinants $\pm 1$ and its subgroups. For matrices with determinant 1, further results are known, namely decidability of vector reachability [13] and NP-completeness of the membership problem [2]. If all matrices in $\mathcal{M}$ have determinant 1 and $\mathcal{M}$ is closed under inverses, then $\langle \mathcal{M} \rangle$ is a group. In this case, one can decide in polynomial time for a given matrix $M$ whether $M$ or $-M$ is in $\langle \mathcal{M} \rangle$ [11].

The contribution of this paper centres on upper-triangular integer matrices, i.e., integer matrices of the form \[
\begin{pmatrix}
a & b \\
0 & c
\end{pmatrix}.
\] The motivation for studying these matrices is twofold. On the one hand, decidability of the membership, vector reachability, and scalar reachability problems are still challenging, and indeed open, despite the seemingly strong restriction on the matrix shape. On the other hand, other deceptively simply formulated reachability problems in one dimension are closely related to such matrices. Specifically, it is not hard to show (see Proposition 1) that the problem of affine reachability over $\mathbb{Q}$ reduces to scalar reachability. Affine reachability over $\mathbb{Q}$ asks, given a set of affine rational functions in one variable and two rational numbers $x, y \in \mathbb{Q}$, whether $x$ can be transformed into $y$ using one or more applications of the given functions.

Decidability of affine reachability over $\mathbb{Q}$ is open. This problem can be viewed as a “nondeterministic” variant of the reachability problem with a single, but only piecewise affine, function, so-called piecewise affine maps; this problem is not known to be decidable either, see [15, 6]. A variant over $\mathbb{Z}$ is studied in [3].

Contribution and organization of the paper. In Section 2 we observe tight connections of our problems (membership, vector reachability, scalar reachability) to reachability problems of affine functions.

In Section 3 we study the case with $\pm 1$ on the diagonal. Establishing a connection with so-called $\mathbb{Z}$-VASS [12] allows us to prove NP-completeness, although we show that the case where all matrices have determinant $-1$ is in P by a reduction to a linear system of Diophantine equations over the integers.

In Section 4 we study vector reachability. We show that the problem is hard for affine reachability over $\mathbb{Q}$, hence decidability requires a breakthrough. But for the case where the bottom-right entries are non-zero, vector reachability can be decided in $\text{PSPACE}$ by a reduction to reachability in register machines over $\mathbb{Z}$ with polynomial updates [9].

In Section 5 we study the membership problem. If both diagonal entries are non-zero, we show that the problem is NP-complete, which in turn shows NP-completeness of the following problem: given $n + 1$ non-constant affine functions over $\mathbb{Z}$ in one variable, can the $n + 1$st function be represented as a composition of the other $n$ functions? The case where only one of the diagonal entries is restricted to be non-zero is decidable in $\text{PSPACE}$. Finally, for the case where both diagonal entries may be 0, we establish reductions between membership and scalar reachability, suggesting that decidability of membership would also require a breakthrough.

In Section 6 we turn to the mortality problem. We show that mortality is NP-hard even when the non-singular matrices in $\mathcal{M}$ are upper-triangular with 1s on the diagonal. This strengthens the main result of [11] and simplifies its proof. Finally, leveraging recent results from [13, 2], we show that mortality of two-dimensional integer matrices (not necessarily triangular) with determinants $+1$ or 0 is NP-complete.
2 Preliminaries

We write $\mathbb{Z}$ for the set of integer numbers, $\mathbb{N} = \{0, 1, 2, \ldots\}$ for the set of nonnegative integers, and $\mathbb{Q}$ for the set of rationals. We write $\text{UT}$ for the set (and the monoid under matrix multiplication) of two-dimensional upper-triangular integer matrices:

$$\text{UT} := \left\{ \begin{pmatrix} x & y \\ 0 & z \end{pmatrix} \mid x, y, z \in \mathbb{Z} \right\}$$

We may drop the 0 in the bottom-left corner and write $\begin{pmatrix} x & y \\ z \end{pmatrix}$ for matrices in $\text{UT}$. Let $\Phi(A)$ be a constraint for $A \in \text{UT}$. We write $\text{UT}[\Phi(A)] := \{ A \in \text{UT} \mid \Phi(A) \}$, e.g., $\text{UT}[A_{22} = 1]$ denotes the set of all upper-triangular matrices whose bottom-right coefficient equals 1.

For a finite set $\mathcal{M}$ of matrices, we write $\langle \mathcal{M} \rangle$ for the monoid generated by $\mathcal{M}$ under matrix multiplication. In this paper we consider mainly the following reachability problems:

- **Membership**: Given a finite set $\mathcal{M} \subseteq \text{UT}$, and a matrix $T \in \text{UT}$, is $T \in \langle \mathcal{M} \rangle$?
- **Vector reachability**: Given a finite set $\mathcal{M} \subseteq \text{UT}$, and vectors $\vec{x}, \vec{y} \in \mathbb{Z}^2$, is there a matrix $M \in \langle \mathcal{M} \rangle$ such that $M\vec{x} = \vec{y}$?
- **Scalar reachability**: Given a finite set $\mathcal{M} \subseteq \text{UT}$, vectors $\vec{x}, \vec{y} \in \mathbb{Z}^2$, and a scalar $\lambda \in \mathbb{Z}$, is there a matrix $M \in \langle \mathcal{M} \rangle$ such that $\vec{y}^T M \vec{x} = \lambda$? We refer to the special case with $\lambda = 0$ as the 0-reachability problem.

We write $\text{Aff}(\mathbb{Z})$ for the set (and the monoid under function composition) of affine functions:

$$\text{Aff}(\mathbb{Z}) := \{ x \mapsto ax + b \mid a, b \in \mathbb{Z} \} \subseteq \mathbb{Z}^\mathbb{Z}$$

Define $\text{Aff}(\mathbb{Q})$ similarly, with $\mathbb{Z}$ replaced by $\mathbb{Q}$. For a finite set $\mathcal{A}$ of affine functions, we write $\langle \mathcal{A} \rangle$ for the monoid (i.e., including the identity function $x \mapsto x$) generated by $\mathcal{A}$ under function composition. The motivation to study the matrix reachability problems above is their relationship to the following one-dimensional affine reachability problems:

- **Affine membership over $\mathbb{Z}$**: Given a finite set $\mathcal{A} \in \text{Aff}(\mathbb{Z})$, and a function $f \in \text{Aff}(\mathbb{Z})$, is $f \in \langle \mathcal{A} \rangle$?
- **Affine reachability over $\mathbb{Z}$**: Given a finite set $\mathcal{A} \in \text{Aff}(\mathbb{Z})$, and numbers $x, y \in \mathbb{Z}$, is there a function $f \in \langle \mathcal{A} \rangle$ such that $f(x) = y$?
- **Affine reachability over $\mathbb{Q}$**: The same problem with $\mathbb{Z}$ replaced by $\mathbb{Q}$.

The following proposition links those problems:

**Proposition 1.**

1. **Affine membership over $\mathbb{Z}$ is equivalent to (matrix) membership restricted to matrices with 1 in the bottom-right corner.**
2. **Affine reachability over $\mathbb{Z}$ is equivalent to vector reachability restricted to matrices with 1 in the bottom-right corner.**
3. **Affine reachability over $\mathbb{Q}$ is equivalent to 0-reachability restricted to matrices with non-zero entries in the bottom-right corner and vectors $\vec{x}, \vec{y} \in \mathbb{Z}^2$ such that the bottom entry of $\vec{x}$ and the top entry of $\vec{y}$ are non-zero.**

**Proof.** Items 1 and 2 follow from the isomorphism $\varphi : \text{Aff}(\mathbb{Z}) \to \text{UT}$ with $\varphi(x \mapsto ax + b) = \begin{pmatrix} a & b \\ 1 \end{pmatrix}$, and the injection $\varphi' : \mathbb{Z} \to \mathbb{Z}^2$ with $\varphi'(x) = (x, 1)^T$. More specifically, we have $\varphi(f_2 \circ f_1) = \varphi(f_2) \varphi(f_1)$ and $\varphi'(f(x)) = \varphi(f) \varphi'(x)$. 
For item 3 consider the quotient $UT/\sim$ of $UT$ by the equivalence $\sim$ with \[
\begin{pmatrix} a_1 & b_1 \\ c_1 & c_1 \end{pmatrix} \sim \begin{pmatrix} a_2 & b_2 \\ c_2 & c_2 \end{pmatrix}
\] if and only if there is $\lambda \in \mathbb{Q} \setminus \{0\}$ with \[
\begin{pmatrix} a_1 & b_1 \\ c_1 & c_1 \end{pmatrix} = \lambda \begin{pmatrix} a_2 & b_2 \\ c_2 & c_2 \end{pmatrix}.
\] We define a similar injection $\varphi : \text{Aff}(Q) \to UT/\sim$ as above such that $\varphi(x \mapsto \frac{ax + b}{c}) = \begin{pmatrix} a & b \\ c & c \end{pmatrix}$ where $c \neq 0$. It is an isomorphism as: \[
\varphi \left( x \mapsto \frac{a_2 a x + b_1 + b_2}{c_2} \right) = \varphi \left( x \mapsto \frac{a_2 a x + a_2 b_1 + b_2 c_1}{c_2 c_1} \right) = \begin{pmatrix} a_2 & b_2 \\ c_2 & c_1 \end{pmatrix} \begin{pmatrix} a_1 & b_1 \\ c_1 & c_1 \end{pmatrix}
\]

Define also the equivalence $\sim'$ such that $(p_1, q_1)^T \sim' (p_2, q_2)^T$ holds if and only if there is $\lambda \in \mathbb{Q} \setminus \{0\}$ such that $(p_1, q_1)^T = \lambda (p_2, q_2)^T$. Finally, define the injection $\varphi' : Q \to \mathbb{Z}^2/\sim'$ with $\varphi' \left( \frac{p}{q} \right) = \left( p, q \right)^T$. Then we have, similarly as in items 1 and 2: \[
\varphi' \left( \frac{a p + b}{c} \right) = \begin{pmatrix} a & b \\ c & c \end{pmatrix} \begin{pmatrix} p \quad q \end{pmatrix} = \varphi \left( x \mapsto \frac{a x + b}{c} \right) \varphi' \left( \frac{p}{q} \right)
\]

It follows that we have $\frac{a x + b}{c} = \frac{y_2}{y_1}$ if and only if $\left( y_1, y_2 \right) \sim' \left( a, b \right) \left( \frac{x_1}{x_2} \right)$, which in turn is equivalent to $(y_2 - y_1) \left( \frac{a}{b} \right) \left( \frac{x_1}{x_2} \right) = 0$. Item 3 follows.

Simple reductions show that these problems are all NP-hard:

\begin{itemize}
  \item \textbf{Proposition 2.} Membership, vector reachability and 0-reachability are all NP-hard, even for matrices with only 1s on the diagonal, and for $\vec{x} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$ and for $\vec{y} = \begin{pmatrix} t \\ 1 \end{pmatrix}$ (for vector reachability) resp. $\vec{y}^T = \begin{pmatrix} 1 & -t \end{pmatrix}$ (for 0-reachability).
\end{itemize}

\textbf{Proof.} The following problem, \textit{multi-subset-sum}, is known to be NP-complete, see the comment under “[MP10] Integer Knapsack” in [10]: given a finite set $\{a_1, \ldots, a_k\} \subseteq \mathbb{N}$ and a value $t \in \mathbb{N}$, decide whether there exist coefficients $a_1, \ldots, a_k \in \mathbb{N}$ such that $\sum_{i=1}^{k} a_i a_i = t$.

Given an instance of multi-subset-sum, construct \[
\mathcal{M} := \left\{ \begin{pmatrix} 1 & a_i \\ 1 & 1 \end{pmatrix} \mid i \in \{1, \ldots, k\} \right\} \quad \text{and} \quad T := \begin{pmatrix} 1 & t \\ 1 & 1 \end{pmatrix}.
\]

Using the observation that $\begin{pmatrix} 1 & a \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & b \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} 1 & a + b \\ 1 & 1 \end{pmatrix}$ and that, hence, $\langle \mathcal{M} \rangle$ is commutative, it is straightforward to verify that the instance of multi-subset-sum is positive if and only if $T \in \langle \mathcal{M} \rangle$. The proofs for vector reachability and 0-reachability are similar.

\section{Determinant $\pm 1$}

In this section we study the case where the monoid $\langle \mathcal{M} \rangle$ is restricted to matrices with determinants $\pm 1$, i.e., with $\pm 1$ on the diagonal. In this case, the matrices $M \in \langle \mathcal{M} \rangle$ are characterized by the sign pattern on the diagonal and the top-right entry. Our problems become NP-complete under this restriction, but are in P if the determinants are $-1$. First we prove the following lemma:
Lemma 3. Let $\mathcal{M} \subseteq UT|A_{11}| = |A_{22}| = 1$. There exists an existential Presburger formula $\varphi(s, a, t)$ that can be constructed in time polynomial in the description of $\mathcal{M}$ such that $\varphi(s, a, t)$ holds if and only if $\left( \begin{array}{cc} s & a \\ t & \end{array} \right) \in \langle \mathcal{M} \rangle$.

Proof. Let $\mathcal{M} \subseteq UT|A_{11}| = |A_{22}| = 1$. We reduce the problem whether $\left( \begin{array}{cc} s & a \\ t & \end{array} \right) \in \langle \mathcal{M} \rangle$ holds for some integers $s, a, t \in \mathbb{Z}$ to a reachability problem on one-dimensional $\mathbb{Z}$-VASS (integer vector addition systems with states) \cite{12}. The reachability relation relation of one-dimensional $\mathbb{Z}$-VASS is known to be effectively definable by an existential Presburger formula of polynomial length, see, e.g., \cite{12}, which then entails the claim to be shown.

A (one-dimensional) $\mathbb{Z}$-VASS can be described as a triple $(Q, \Sigma, \delta)$ where $Q$ is a finite set of states, $\Sigma \subset \mathbb{Z}$ is a finite set of integer numbers, and $\delta \subseteq Q \times \Sigma \times Q$ is a finite transition relation. A run from $q_0 \in Q$ to $q_n \in Q$ of length $n$ is a sequence $q_0a_1q_1a_2q_2 \cdots a_nq_n$ such that $(q_i, a_i, q_{i+1}) \in \delta$ holds for all $i \in \{1, \ldots, n\}$. The value of such a run is defined as $\sum_{i=1}^{n} a_i$. The $\mathbb{Z}$-VASS reachability problem is to decide, given a $\mathbb{Z}$-VASS, two states $q, q' \in Q$, and a number $t \in \mathbb{Z}$, whether there is a run from $q$ to $q'$ with value $t$.

We give a polynomial reduction from the membership problem to the reachability problem for $\mathbb{Z}$-VASS: Define $Q := \{(+1, +1), (+1, -1), (-1, +1), (-1, -1)\}$, each state reflecting the diagonal. A transition $(q, a, q') \in \delta$ corresponds to a multiplication with a matrix $M \in \mathcal{M}$. More precisely, for each state $(s, t)$ and each $\left( \begin{array}{c} s' \\ a' \\ t' \end{array} \right) \in \mathcal{M}$ we add a transition $((s, t), s't'a', (ss', tt'))$. We claim that there exists a run from $(+1, +1)$ to $(s_n, t_n)$ of length $n$ and value $a \in \mathbb{Z}$ if and only if there are matrices $M_1, \ldots, M_n \in \mathcal{M}$ such that $M_1 \cdots M_n = \left( \begin{array}{ccc} s_n & t_n a \\ t_n & \end{array} \right)$. The claim can be proven by a straightforward induction on $n$ (see Appendix A for the proof). The claim implies that there is $\left( \begin{array}{cc} s & a \\ t & \end{array} \right) \in \langle \mathcal{M} \rangle$ if and only if there is a run from $(+1, +1)$ to $(s, t)$ of value $t_n a$. Recall that the reachability relation of the $\mathbb{Z}$-VASS is definable in an existential Presburger formula of polynomial size, and thus so is the query $\left( \begin{array}{cc} s & a \\ t & \end{array} \right) \in \langle \mathcal{M} \rangle$. The statement follows.

Theorem 4. Let $\mathcal{M} \subseteq UT$ be with $\det(M) \in \{1, -1\}$ for all $M \in \mathcal{M}$.

1. Membership, vector reachability and scalar reachability are NP-complete.
2. They are NP-hard even for $\mathcal{M} \subseteq UT|A_{11} = A_{22} = 1|$ and for $\mathcal{M} \subseteq UT|A_{11} = A_{22} = -1|$.
3. They are in $\mathcal{P}$ if $\det(M) = -1$ for all $M \in \mathcal{M}$.

Proof. For item 1 the lower bound follows from Proposition 3. The upper bound for membership follows from Lemma 3 and the folklore result that existential Presburger arithmetic is in NP \cite{3, 21}. Vector and scalar reachability are easily reduced to membership, hence they are also in NP. This completes the proof of item 1.

Towards item 2, NP-hardness of the case $UT|A_{11} = A_{22} = 1|$ follows from the proof of Proposition 3. For the case $UT|A_{11} = A_{22} = -1|$ we adapt this reduction by constructing $\mathcal{M} := \left\{ \left( \begin{array}{cc} -1 & -a_i \\ -1 & \end{array} \right) \mid i \in \{1, \ldots, k\} \right\} \cup \left\{ \left( \begin{array}{cc} -1 & 0 \\ -1 & \end{array} \right) \right\}$ and $T := \left( \begin{array}{cc} 1 & t \\ 1 & \end{array} \right)$.

Note that $\left( \begin{array}{cc} -1 & -a \\ -1 & \end{array} \right) \left( \begin{array}{cc} -1 & -b \\ -1 & \end{array} \right) = \left( \begin{array}{cc} 1 & a + b \\ -1 & \end{array} \right)$. The additional (negative identity) matrix ensures that an even number of matrices from $\mathcal{M}$ can be used to form the product $T$. 
NP-hardness for vector reachability and 0-reachability are similar. This completes the proof of item 2.

Towards item 3, we will give an explicit description of \( \langle M \rangle \), such that membership can be checked in polynomial time. We focus on matrix products of even length \( M_1 \cdots M_{2n} \in \langle M \rangle \). These are exactly the matrices in \( \langle M \rangle \) with determinant 1. The extension to odd-length products (which have determinant \(-1\)) will be straightforward, as such products simply arise from even-length products multiplied with a single element of \( M \). The even-length products also form a monoid, finitely generated by \( M' := \{ M_1 M_2 \mid M_1 \in M, \, M_2 \in M \} \), and all matrices in \( M' \) have \((+1, +1)\) or \((-1, -1)\) on the diagonal. Clearly, \( M' \) can be computed in polynomial time. Let \( M'_+ \) and \( M'_- \) be such that \( M' = M'_+ \cup M'_- \), and \( M'_+ \) is the set of matrices from \( M' \) that have \((+1, +1)\) on the diagonal, and \( M'_- \) is defined analogously. For all \( \begin{pmatrix} -1 & c \\ 0 & -1 \end{pmatrix} \in M'_- \), the matrix \( \begin{pmatrix} -1 & -c \\ 0 & -1 \end{pmatrix} \) is also in \( M'_- \), as

\[
\begin{pmatrix} +1 & a \\ -1 & +1 \end{pmatrix} \begin{pmatrix} -1 & b \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} -1 & a+b \\ 0 & -1 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} -1 & b \\ 0 & -1 \end{pmatrix} \begin{pmatrix} +1 & a \\ -1 & +1 \end{pmatrix} = \begin{pmatrix} -1 & -a-b \\ 0 & -1 \end{pmatrix}.
\]

The analogous statement for \( M'_+ \) holds as well.

Let \( g \in \mathbb{N} \) denote the gcd of all top-right entries in \( M'_+ \), with \( g = 0 \) in case all those entries are 0. Then \((M'_+) = \left\{ \begin{pmatrix} 1 & gZ \\ 0 & 1 \end{pmatrix} \right\} \), where here and later in this proof we write \( \begin{pmatrix} a & B \\ c & e \end{pmatrix} \) with \( B \subseteq \mathbb{Z} \) to denote the set \( \left\{ \begin{pmatrix} a & b \\ c & e \end{pmatrix} \mid b \in B \right\} \), and \( gZ \) are the integer multiples of \( g \). Given two sets of matrices \( A_1, A_2 \), we write \( A_1 A_2 \) to denote the set \( \{ A_1 A_2 \mid A_1 \in A_1, \, A_2 \in A_2 \} \). For \( k \in \mathbb{N} \), let \( P_k \) denote the products of \( M' \) where exactly \( k \) factors are from \( M'_- \). We have \( P_0 = \left\{ \begin{pmatrix} 1 & gZ \\ 0 & 1 \end{pmatrix} \right\} \). Let \( S \subset \mathbb{Z} \) such that \( M'_- = \left\{ \begin{pmatrix} -1 & S \\ 0 & -1 \end{pmatrix} \right\} \) and define \( S^{\oplus k} := \left\{ \sum_{i=1}^k s_i \mid s_i \in S \right\} \).

We have:

\[
\begin{align*}
P_1 &= \begin{pmatrix} 1 & gZ \\ 0 & 1 \end{pmatrix} \begin{pmatrix} -1 & S \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} -1 & S+gZ \\ 0 & -1 \end{pmatrix} \\
P_2 &= P_1 P_1 = \begin{pmatrix} -1 & S+gZ \\ 0 & -1 \end{pmatrix} \begin{pmatrix} -1 & S+gZ \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} 1 & S^{\oplus 2} + gZ \\ 0 & 1 \end{pmatrix} \\
P_3 &= P_2 P_1 = \begin{pmatrix} 1 & S^{\oplus 2} + gZ \\ 0 & 1 \end{pmatrix} \begin{pmatrix} -1 & S+gZ \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} -1 & S^{\oplus 3} + gZ \\ 0 & -1 \end{pmatrix}
\end{align*}
\]

Continuing this pattern, we see that the set of matrices from \( \langle M \rangle \) with \((+1, +1)\) on the diagonal is

\[
\bigcup_{k \in \mathbb{N}} P_{2k} = \bigcup_{k \in \mathbb{N}} \left\{ \begin{pmatrix} 1 & S^{\oplus 2k} + gZ \\ 0 & 1 \end{pmatrix} \right\},
\]

and the set with \((-1, -1)\) on the diagonal is

\[
\bigcup_{k \in \mathbb{N}} P_{2k+1} = \bigcup_{k \in \mathbb{N}} \left\{ \begin{pmatrix} -1 & S^{\oplus 2k+1} + gZ \\ 0 & -1 \end{pmatrix} \right\}.
\]

It remains to show that we can efficiently check membership in such sets. Let \( S = \{ s_1, \ldots, s_m \} \).

Suppose \( T = \begin{pmatrix} -1 & t \\ 0 & -1 \end{pmatrix} \) and we want to check whether \( T \in \bigcup_{k \in \mathbb{N}} P_{2k+1} \). This holds if and
only if the linear system given by the two equalities
\[ t = \sum_{i=1}^{m} s_i x_i + gy \quad \quad \quad 2k + 1 = \sum_{i=1}^{m} x_i \]
has an integer solution in the variables \( x_i, y, k \). It is known that affine Diophantine equations can be solved in polynomial time \([20]\). The case where the diagonal entries of \( T \) are \((+1, +1)\) is similar. As remarked above, the extension to odd-length products, which have diagonals \((+1, -1)\) or \((-1, +1)\), is straightforward. The vector reachability and scalar reachability problems (with the restriction on determinants in place) easily reduce to the membership problem, hence are also in \( \mathcal{P} \).

\[ \mathbf{4 \ Vector \ Reachability} \]

Let \( \mathbb{Z}[x] \) denote the set of polynomials over \( x \) with integer coefficients. A polynomial register machine (PRM) is a tuple \( R = (Q, \Delta, \lambda) \) where \( Q \) is a finite set of states, \( \Delta \subseteq Q \times Q \) is the transition relation, and \( \lambda: \Delta \rightarrow \mathbb{Z}[x] \) is the transition labelling function, labelling each transition with an update polynomial. We write \( q \xrightarrow{p(x)} q' \) whenever \( (q, q') \in \Delta \) and \( \lambda((q, q')) = p(x) \). The set \( C(R) \) of configurations of \( R \) is \( C(R) := Q \times \mathbb{Z} \). By \( R \subseteq C(R) \times C(R) \) we denote the one-step relation given by

\[ (q, a) \rightarrow_R (q', b) \iff q \xrightarrow{p(x)} q' \text{ and } b = p(a). \]

Let \( \rightarrow_R^* \) be the reflexive-transitive closure of \( \rightarrow_R \). The following theorem is the main result of \([9]\).

\[ \mathbf{\triangleright \ Theorem 5 \ ([9])}. \text{ The following problem is decidable in PSPACE: Given a PRM } R \text{ and two configurations } (q, a), (q', b) \in C_R, \text{ does } (q, a) \rightarrow_R^* (q', b) \text{ hold?} \]

We show:

\[ \mathbf{\triangleright \ Theorem 6}. \text{ The vector reachability problem for } UT[A_{22} \neq 0] \text{ is in PSPACE.} \]

\[ \text{Proof.} \text{ We construct a nondeterministic Turing machine } T \text{ that accepts the reachability problem for } UT[A_{22} \neq 0] \text{ in polynomial space. Let } M \subseteq UT[A_{22} \neq 0] \text{ and } \vec{x}, \vec{y} \in \mathbb{Z}^2 \text{ be an instance of the reachability problem, that is, } T \text{ has to check whether } M \cdot \vec{x} = \vec{y} \text{ holds for some } M \in (M). \]

Assume that \( M^{(1)} \cdot \ldots \cdot M^{(k)} \cdot x = y \) holds for some \( M^{(1)}, \ldots, M^{(k)} \in M \). Observe that for all \( A \in M \) and all \( z, z' \in \mathbb{Z}^2 \) such that \( Az = z' \), we have \( z'_2 = A_{22} z_2 \). From this observation we conclude:

\[ \text{1. If } x_2 \neq 0, \text{ then } z_2 \neq 0, \text{ too, and the number of indices } 1 \leq i \leq k \text{ where } |M^{(i)}_{12}| > 1 \text{ is bounded by a function in } \mathcal{O}(\log(|y_2|)). \]

\[ \text{2. If } x_2 = 0 \text{ or } y_2 = 0, \text{ then } x_2 = y_2 = 0 \text{ and } y_1 = M^{(1)}_{11} \cdot \ldots \cdot M^{(k)}_{11} \cdot x_1 \text{ must hold.} \]

Let us first consider the case where \( x_2 = 0 \) or \( y_2 = 0 \) holds. In this case, \( T \) rejects the input if \( x_1 \neq y_2 \). Otherwise, \( T \) needs to check whether \( y_1 \) can be written as a product \( M^{(1)}_{11} \cdot \ldots \cdot M^{(k)}_{11} \cdot x_1 \) for some indices \( 1, \ldots, k \), which can be done in polynomial space (even in NP), since \( k \) can be bounded by \( \mathcal{O}(\log(|y_1|)) \).

Now consider the case where \( |x_2| > 0 \) and \( |y_2| > 0 \) holds. By the above observation, if the reachability problem has a solution, it can be given by

\[ \vec{y} = A^{(l+1)} \cdot B^{(l)} \cdot A^{(l)} \cdot \ldots \cdot B^{(2)} \cdot A^{(2)} \cdot B^{(1)} \cdot A^{(1)} \cdot \vec{x} \]

(1)
On Semigroups of Two-Dimensional Upper-Triangular Integer Matrices

the length of \( l \in \mathbb{N} \) is polynomially bounded in the size of the input,
\[ B^{(i)} \in \text{UT}[\| A_{22} \| > 1] \cap M \text{ for every } i, \]
\[ A^{(i)} \text{ can be written as product of matrices from } \text{UT}[\| A_{22} \| = 1] \cap M. \]

Notice that the matrices from \( \text{UT}[\| A_{22} \| = 1] \) behave like affine update polynomials in a PRM, with the register value stored in the first component of the vector. This suggests the following approach: \( \mathcal{T} \) guesses the sequence of matrices \( B = B^{(1)}, \ldots, B^{(l)} \) and constructs a PRM \( R_B \), whose size is polynomially bounded in the size of the input, such that \((q, x_1) \rightarrow^*_{R_B} (q', y_1)\) holds for some fixed states \( q, q' \) if the reachability problem has a solution of the form given in \((1)\). The register machine only needs to store its finite states and constructs a PRM \( T \), with the register value stored in the first component of the vector. This follows by applying Theorem 5.

More formally, fix some guess \( B = B^{(1)}, \ldots, B^{(l)} \) by \( \mathcal{T} \). For a given matrix \( M \in \text{UT} \) and a given integer \( \alpha \), let \( f_{M, \alpha} \) be the affine function given by
\[ f_{M, \alpha}(a) := M_{11} \cdot a + M_{12} \cdot \alpha. \]

Assume \((1)\) holds for the guessed \( B \) and some \( A^{(1)}, \ldots, A^{(l+1)} \). Let \( m \in \mathbb{N} \) and \( M^{(i)} \in \mathcal{M} \), \( 1 \leq i \leq m \) be such that
\[ M^{(m)} \cdot M^{(m-1)} \cdot \ldots \cdot M^{(1)} = A^{(l+1)} \cdot B^{(l)} \cdot A^{(l)} \cdot \ldots \cdot B^{(2)} \cdot A^{(2)} \cdot B^{(1)} \cdot A^{(1)}. \]
For \( 0 \leq i \leq m \), set \( \alpha(i) := x_2 \cdot \prod_{j=1}^{i-1} M^{(j)}_{22} \). Then it is easy to verify that the following holds:
\[ y_1 = (f_{M^{(m)}, \alpha(m)} \circ f_{M^{(m-1)}, \alpha(m-1)} \circ \cdots \circ f_{M^{(1)}, \alpha(1)})(x_1) \]
\[ y_2 = M^{(m)}_{22} \cdot \alpha(m) \]
\[ \alpha(i) \in \left\{ \pm x_2 \cdot \prod_{j=1}^{k} B^{(j)}_{22} \mid k \in \{0, \ldots, l\} \right\} \text{ for every } 1 \leq i \leq m. \]

The PRM \( R_B = (Q, \Delta, \lambda) \) can then be defined as \( Q := \left\{ \pm x_2 \cdot \prod_{j=1}^{l} B^{(j)}_{22} \mid k \in \{0, \ldots, l\} \right\}, \)
\[ \Delta := Q \times Q, \]
and the labelling function \( \lambda \) is uniquely defined by the following constraints:
\[ \lambda((\alpha_1, \alpha_2)) \subseteq \left\{ f_{M, \alpha_1} \mid M \in \mathcal{M} \right\} \text{ for every } (\alpha_1, \alpha_2) \in Q \times Q, \]
\[ f_{M, \alpha_1} \in \lambda((\alpha_1, \alpha_2)) \iff \alpha_2 = M_{22} \cdot \alpha_1 \text{ for every } (\alpha_1, \alpha_2) \in Q \times Q, \]
\[ M \in \mathcal{M}. \]

By construction, \((x_2, x_1) \rightarrow^*_{R_B} (y_2, y_1)\) holds if \((1)\) holds for some matrices \( A^{(i)} \), \( 1 \leq i \leq l + 1 \). Conversely, if \((x_2, x_1) \rightarrow^*_{R_B} (y_2, y_1)\) holds for some \( M_1, \ldots, M_k \in \mathcal{M} \), then \( y = M_k \cdot \cdots \cdot M_1 \cdot x \) is a witness for reachability. Notice that \( R_B \) is polynomial in the size of the input, and thus by Theorem 5 \( \mathcal{T} \) can verify in polynomial space whether matrices \( A^{(i)} \) exist such that \((1)\) holds for the guess \( B \), or a permuted subsequence of \( B \). This completes the proof.

Without the restriction on \( \text{UT}[A_{22} \neq 0] \) the vector reachability problem becomes hard for affine reachability over \( Q \):

\[ \textbf{Theorem 7.} \text{ There is a polynomial-time Turing reduction from affine reachability over } Q \text{ to vector reachability.} \]
Proof. Let an instance of affine reachability over \(\mathbb{Q}\) be given. We first assume that all input functions are non-constant. Then we use the reduction from Proposition 3 to obtain an instance of the 0-reachability problem: \(M \subseteq UT[A_{11} \neq 0, A_{22} \neq 0]\) with \(x_1 \neq 0\) and \(y_1 \neq 0\). Define \(T := \begin{pmatrix} y_1 & y_2 \\ x_1 & x_2 \end{pmatrix}\) and \(M' := M \cup \{T\}\). We show that the instance of the 0-reachability problem is positive if and only if the vector reachability for \(M'\) and \(\vec{x}\) and \(\vec{y}\) is positive. Suppose the instance of the 0-reachability problem is positive. Then there is \(M' \in \langle M \rangle\) such that \((y_1 \ y_2) M \vec{x} = 0\), thus \(TM \vec{x} = 0\), so \(\vec{y}\) is reachable from \(\vec{x}\). Conversely, suppose the instance of the 0-reachability problem is negative. Let \(M \in \langle M \rangle\). Then \(M \vec{x} \neq 0\), as the bottom component of \(M \vec{x}\) is non-zero. Since the instance of the 0-reachability problem is negative, we have \(TM \vec{x} = \begin{pmatrix} t \\ 0 \end{pmatrix}\) for some \(t \neq 0\). Since the top-left component of all matrices in \(M'\) is non-zero, it follows that \(M'TM \vec{x} \neq 0\) holds for all \(M' \in \langle M' \rangle\). Thus, \(M'' \vec{x} \neq 0\) holds for all \(M'' \in \langle M' \rangle\), and so the instance of the vector reachability problem is negative.

Now we allow input functions of affine reachability to be constant. Suppose the constant functions are \(f_i : x \mapsto 0x + c_i\) for \(i \in \{1, \ldots, n\}\) for some \(n \in \mathbb{N}\). It is easy to see that then the affine reachability problem can be solved by removing all \(f_i\) from the set of functions and checking affine reachability starting from \(c_i\), where \(i \in \{1, \ldots, n\}\), one by one. These instances can be reduced to vector reachability, as described before.

5 Membership

In this section we study the membership problem. As we will see, the difficulty depends on the location of 0s: roughly speaking, the more 0s on the diagonal the harder the problem. Any product of upper-triangular matrices is non-zero on the top-left (bottom-right, respectively) if and only if all factors are non-zero on the top-left (bottom-right, respectively). So when we speak of the membership problem for, e.g., \(UT[A_{11} \neq 0]\), the restriction refers both to \(M\) and the target matrix \(T\).

The case with no 0s on the diagonal is \(\text{NP}\)-complete:

\textbf{Theorem 8.} The membership problem for \(\text{UT}[A_{11} \neq 0 \land A_{22} \neq 0]\) is \(\text{NP}\)-complete.

Proof. The lower bound was shown in Proposition 3. For the upper bound, we construct an \(\text{NP}\) Turing machine. Fix \(M\) and \(T\). Assume for the moment that \(T\) can be written as a product \(T = M^{(k)} \cdots M^{(1)}\) of matrices from \(M\). Let \(l\) be the number of indices \(i > 1\) where \(M^{(i)} \in \text{UT}[|A_{11}| > 1 \lor |A_{22}| > 1]\) holds. Since \(T_{i,i} = \prod_{j=1}^{k} M^{(j)}_{i,i}\) holds for both \(i \in \{1, 2\}\), the number \(l\) can be bounded by \(\mathcal{O}(\log(|T_{11}|) + \log(|T_{22}|))\), and \(T\) can be written as

\[T = A^{(l+1)} B^{(l)} A^{(l-1)} \cdots B^{(1)} A^{(1)} M^{(1)}\] (4)

such that \(B^{(j)} \in \text{UT}[|A_{11}| > 1 \lor |A_{22}| > 1]\) and \(A^{(j)} \in \{\text{UT}||A_{11}| = 1, |A_{22}| = 1\} \cup \{I\}\) for every \(j\).

The Turing machine guesses matrices \(B^{(1)}, \ldots, B^{(l)}\) and the matrix \(M^{(1)}\) and constructs in polynomial time an existential Presburger formula \(\varphi(t_1, t_2, t_3)\) that satisfies \(t_1 = T_{11}, t_2 = T_{12}, t_3 = T_{22}\) if and only if \(T\) can be written as a product of the form given in (4) for the guessed \(B^{(j)}\) and \(M^{(1)}\). By Lemma 3 such a formula \(\varphi(t_1, t_2, t_3)\) exists and can be efficiently constructed. The claim then follows from the fact that \(\varphi(t_1, t_2, t_3)\) is existential Presburger of size polynomial in the input, and that the existential Presburger fragment is in \(\text{NP}\) [3] [21].
On Semigroups of Two-Dimensional Upper-Triangular Integer Matrices

The proof of Proposition 1 with the isomorphism between affine functions over \( \mathbb{Z} \) and upper-triangular matrices with 1 on the bottom-right shows that non-constant functions correspond to matrices that do not have 0s on the diagonal. Hence we have:

- **Corollary 9.** Affine membership over \( \mathbb{Z} \) with non-constant functions is \( \text{NP-complete} \).

The case where 0s are allowed at one of the diagonal positions can be reduced to vector reachability:

- **Theorem 10.** The membership problems for \( UT[A_{11} \neq 0] \) and for \( UT[A_{22} \neq 0] \) are in \( \text{PSPACE} \).

**Proof.** We give a proof sketch for \( UT[A_{22} \neq 0] \); the detailed proof can be found in the appendix. If \( T_{11} \neq 0 \), then a \( \text{PSPACE} \) decision procedure follows from Theorem 8. If \( T_{11} = 0 \), then the problem reduces to a reachability problem with the additional restriction that \( UT[A_{11} = 0] \) must be included in the matrix product. This problem in turn is decidable in \( \text{PSPACE} \) via a straightforward modification of the PRM \( R_B \) in the proof of Theorem 8.

The general membership problem, without restrictions on the position of 0s, is related to (variants of) scalar reachability. Theorems 11 and 12 provide reductions in both ways.

- **Theorem 11.** Let \( s \) be an oracle for the scalar reachability problem. The membership problem is in \( \text{PSPACE}^s \).

**Proof.** Fix some finite \( M \subseteq UT \) and \( T \in UT \). We give a \( \text{PSPACE}^s \) procedure that decides whether \( T \in \langle M \rangle \) holds. We make the following case distinction:

1. \( T = 0 \)
2. \( T \in UT[A_{11} \neq 0 \lor A_{22} \neq 0] \)
3. \( T \in UT[A_{11} = A_{22} = 0 \land A_{12} \neq 0] \)

In the first case, we have \( T \in \langle M \rangle \) if and only if there exist matrices \( M_1 \in UT[A_{11} = 0] \cap M, M_2 \in UT[A_{22} = 0] \cap M \), and \( T = 0 = M_1 \cdot M_2 \) is a solution to the membership problem. The existence of \( M_1, M_2 \) can be checked in polynomial time. In the second case, the problem reduces to \( T \in \langle UT[A_{11} \neq 0] \cap M \rangle \) or \( T \in \langle UT[A_{22} \neq 0] \cap M \rangle \), which is decidable in \( \text{PSPACE} \) by Theorem 10.

Let us now consider the last case. Observe that for every \( M \in UT \), we have \( A \cdot M = M_{22} \cdot A \) and \( M \cdot A = M_{11} \cdot A \) for every \( A \in UT[A_{11} = 0] \) and every \( A \in UT[A_{22} = 0] \), respectively. From this observation, we conclude that \( T \in \langle M \rangle \) if and only if there exist integers \( \alpha, \beta \) and matrices \( A \in UT[A_{11} \neq 0 \land A_{22} = 0], B \in UT[A_{11} = 0 \land A_{22} \neq 0], C \in \langle M \rangle \) such that:

\[
\alpha A, \beta B \in \langle M \rangle \text{ and } T = \alpha A \cdot C \cdot \beta B. \tag{5}
\]

Note that the absolute values of \( \alpha \) and \( \beta \) in (5) are bounded by \( |T_{12}| \). Hence, in order to decide the membership problem, a nondeterministic Turing machine can guess \( \alpha \) and \( \beta \) and the matrices \( A, B \) in polynomial space, test in polynomial space whether \( \alpha A \in \langle M \rangle \) and \( \beta B \in \langle M \rangle \) holds by Theorem 10 and then use the oracle \( s \) to verify the existence of \( C \in \langle M \rangle \) such that \( T_{12} = \alpha \begin{pmatrix} A_{11} & A_{12} \end{pmatrix} C \begin{pmatrix} B_{12} \\ B_{22} \end{pmatrix} \beta \).

- **Theorem 12.** The following sign-invariant version of the scalar-reachability problem is polynomial-time Turing-reducible to the membership problem: Given \( M \subseteq UT \) and column vectors \( \vec{x}, \vec{y} \in \mathbb{Z}^2 \), does \( \vec{y}^T M \vec{x} \in \{-1, 1\} \) hold for some \( M \in \langle M \rangle \)?
Proof. Fix $\mathcal{M}, \vec{x}, \vec{y}$. Let $I$ be the identity, $A := \mathcal{M} \cap UT[A_{22} = 0]$, $B := \mathcal{M} \cap UT[A_{11} = 0]$, $C := (\mathcal{M} \setminus (A \cup B))$, $Y := \begin{pmatrix} y_1 & y_2 \\ 0 & 0 \end{pmatrix}$, and $X := \begin{pmatrix} 0 & x_1 \\ 0 & x_2 \end{pmatrix}$. Set $\mathcal{A}' := A$, if $|y_1| = 1$, otherwise set $\mathcal{A}' := \emptyset$; further set $\mathcal{B}' := B$, if $|x_2| = 1$, otherwise set $\mathcal{B}' := \emptyset$.

We obtain the following equivalences:

\begin{align}
\exists M \in \langle \mathcal{M} \rangle : \vec{y}^T M \vec{x} \in \{\pm 1\} & \Leftrightarrow (6) \\
\exists A \in A \cup \{I\}, B \in B \cup \{I\}, C \in \langle C \rangle : \vec{y}^T \cdot (A \cdot C \cdot B) \cdot \vec{x} \in \{\pm 1\} & \Leftrightarrow (7) \\
\left( \begin{array}{cc} 0 & \pm 1 \\ 0 & 0 \end{array} \right) \in \bigcup_{A \in A \cup \{Y\}, B \in B \cup \{X\}} \langle C \cup \{A, B\} \rangle. & \Leftrightarrow (8)
\end{align}

We provide detailed derivations of these equivalences in Appendix C. Deciding (8) requires polynomially many queries to a membership oracle where input sizes are polynomial in the description of $\mathcal{M}, \vec{x}, \vec{y}$. This entails the claim to be shown.

6 Mortality

Finally we consider the mortality problem: given a finite set $\mathcal{M} \subseteq \mathbb{Z}^{2 \times 2}$ of integer matrices (not necessarily triangular), is the zero matrix $\mathbf{0}$ in $\langle \mathcal{M} \rangle$? In the upper-triangular case the problem is almost trivial: if there is $M \in \langle \mathcal{M} \rangle$ with only zeros on the diagonal, there must be $M_1, M_2 \in \mathcal{M}$ with $M_1 = \begin{pmatrix} 0 & b \\ \ast & c \end{pmatrix}$ and $M_2 = \begin{pmatrix} d & \ast \\ \ast & 0 \end{pmatrix}$—but then $M_1 M_2 = \mathbf{0}$. Hence, we consider mortality for matrices with determinants $+1, 0$ and prove:

**Theorem 13.** The mortality problem for two-dimensional integer matrices (not necessarily triangular) with determinants $+1$ or $0$ is \textsc{NP}-complete. It is \textsc{NP}-hard even if there is one singular matrix and the non-singular matrices are of the form

\[
\begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix}.
\]

Both for the lower and the upper bound we need the following lemma from [5]:

**Lemma 14 ([5 Lemma 2]).** Let $\mathcal{M} \subseteq \mathbb{R}^{2 \times 2}$ be a finite set of matrices. We have $\mathbf{0} \in \langle \mathcal{M} \rangle$ if and only if there are $M_1, \ldots, M_n \in \mathcal{M}$ with $M_1 \cdots M_n = \mathbf{0}$ and $\text{rank}(M_1) = \text{rank}(M_n) < 2$ and $\text{rank}(M_i) = 2$ for all $i \in \{2, \ldots, n-1\}$.

First we prove \textsc{NP}-hardness:

**Proof of the \textsc{NP}-hardness part of Theorem 13.** Concerning \textsc{NP}-hardness, the reduction proving Proposition 2 constructs, given an instance of multi-subset-sum, a set $\mathcal{M}$ of matrices of the form $\begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix}$ and a number $t \in \mathbb{N}$ such that the instance of multi-subset-sum is positive if and only if there is $M \in \mathcal{M}$ with $\begin{pmatrix} 1 & -t \end{pmatrix} M \begin{pmatrix} 0 & 1 \end{pmatrix}^T = 0$. Define the rank-1 matrix

\[
T := \begin{pmatrix} 0 \\ 1 \end{pmatrix} (1 \begin{pmatrix} 0 & 0 \\ 1 & -t \end{pmatrix}
\]

and set $\mathcal{M}' := \mathcal{M} \cup \{T\}$. If there is $M \in \mathcal{M}$ with $\begin{pmatrix} 1 & -t \end{pmatrix} M \begin{pmatrix} 0 \\ 1 \end{pmatrix} = 0$, then $\mathbf{0} = TMT \in \langle \mathcal{M}' \rangle$. Conversely, if there is $\mathbf{0} \in \langle \mathcal{M}' \rangle$, then, by Lemma 14, there is $M \in \mathcal{M}$ with $TMT = \mathbf{0}$, hence $\begin{pmatrix} 1 & -t \end{pmatrix} M \begin{pmatrix} 0 \\ 1 \end{pmatrix} = 0$. \qed
For the upper bound we use results from [13,2]. In accordance with the literature, we define $\text{SL}(2,\mathbb{Z}) := \{ M \in \mathbb{Z}^{2 \times 2} \mid \det(M) = 1 \}$.

**Lemma 15 ([13 Lemma 4]).** Let $\vec{x} = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{Z}^2$ and $\vec{y} = \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} \in \mathbb{Z}^2$ and $M \in \text{SL}(2,\mathbb{Z})$. If $M\vec{x} = \vec{y}$ then $\gcd(x_1, x_2) = \gcd(y_1, y_2)$.

**Theorem 16 ([13 Theorem 8, Corollary 9]).** Let $\vec{x}, \vec{y} \in \mathbb{Z}^2$ with $\vec{x} \neq \vec{0}$. Then one can compute in polynomial time matrices $B, C \in \text{SL}(2,\mathbb{Z})$ such that for every $M \in \text{SL}(2,\mathbb{Z})$ the following equivalence holds:

$$M\vec{x} = \vec{y} \iff \text{there is } k \in \mathbb{Z} \text{ with } M = B \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}^k C$$

In the following theorem, a *regular expression* describes a set of matrices, so that the atomic expressions describe singleton sets, the operator $\cup$ is set union, and the operator $\cdot$ is elementwise multiplication.

**Theorem 17 ([2 Corollary 5.1]).** Given a regular expression over matrices in $\text{SL}(2,\mathbb{Z})$, one can decide in NP whether the identity matrix is in the set described by the regular expression.

Now we can complete the proof of Theorem [13].

**Proof of the upper bound in Theorem [13].** We give an NP procedure. We guess the matrices $M_1, M_n$ from Lemma [14]. Define $\mathcal{M} := \mathcal{M} \cap \text{SL}(2,\mathbb{Z})$. We have to verify that there is a matrix $M \in \langle \mathcal{M} \rangle$ such that $M_1M_2M_n = 0$. Let $\vec{x} = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}^T \in \mathbb{Z}^2$ be a non-zero multiple of a non-zero column of $M_n$ (if $M_n$ does not have a non-zero column, the problem is trivial) such that $\gcd(x_1, x_2) = 1$. This defines $\vec{x}$ uniquely up to a sign. Similarly, let $\vec{y} = \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}^T \in \mathbb{Z}^2$ be a non-zero multiple of a non-zero row of $M_1$ such that $\gcd(y_1, y_2) = 1$. Now it suffices to check whether there is $M \in \langle \mathcal{M} \rangle$ such that $\begin{pmatrix} y_1 & y_2 \end{pmatrix}M\vec{x} = 0$. By Lemma [15], the latter equation is equivalent to $M\vec{x} = \begin{pmatrix} -y_2 & y_1 \end{pmatrix}^T$. Compute the matrices $B, C$ from Theorem [16]. Now it suffices to check whether there are $M \in \langle \mathcal{M} \rangle$ and $k \in \mathbb{Z}$ with $M = B \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}^k C$. Equivalently, one may check whether the identity matrix is in the set described by the regular expression

$$B \left( \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \cup \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix} \right)^* C \left( A_1^{-1} \cup \cdots \cup A_m^{-1} \right)^* \text{ where } \mathcal{M} = \{ A_1, \ldots, A_m \}.$$ 

(Note that $A_i^{-1} \in \text{SL}(2,\mathbb{Z})$.) By Theorem [17], this can be checked in NP.

**7 Conclusion**

Motivated by their connections to affine reachability, we have studied membership, vector reachability, and scalar reachability for two-dimensional upper-triangular integer matrices. To gauge the (relative) difficulty of these problems, we have established several complexity results and reductions. Concerning upper complexity bounds, we have employed a variety of techniques, including existential Presburger arithmetic, Z-VASS, register machines with affine updates over $\mathbb{Z}$, solving linear Diophantine equations over the integers, and special properties of $\text{SL}(2,\mathbb{Z})$. We have also established lower bounds, including hardness of vector reachability for affine reachability over $\mathbb{Q}$, a connection between membership and scalar reachability, and a simpler proof for NP-hardness of the mortality problem.

A Proof of the claim in the proof for Lemma 3

In this section, we provide the omitted proof for the claim in the proof of Lemma 3.

Let the $\mathbb{Z}$-VASS $(Q, \Sigma, \delta)$ be defined as in the proof for Lemma 3: $Q := \{(+1, +1), (+1, -1), (-1, +1), (-1, -1)\}$, and for each state $(s, t)$ and each $(s', a', t') \in \mathcal{M}$ we add a transition $((s, t), st'a', (ss', tt'))$.

We must prove the following proposition:

**Proposition 18.** There exists a run from $(+1, +1)$ to $(s_n, t_n)$ of length $n$ and value $a \in \mathbb{Z}$ if and only if there are matrices $M_1, \ldots, M_n \in \mathcal{M}$ such that $M_1 \cdots M_n = \left(s_n \begin{array}{c} t_n \end{array} a \right)$.

**Proof.** We prove this claim by induction on $n$. The case $n = 0$ implies $a = 0$ and is easy. For the step, suppose there is a run from $(+1, +1)$ to $(s_n, t_n)$ of length $n$ and value $a$. By the induction hypothesis, there are matrices $M_1 \cdots M_n = \left(s_n \begin{array}{c} t_n \end{array} a \right)$. Consider the run of length $n + 1$ and value $a + x$ obtained by extending the previous run by a transition $((s_n, t_n), x, (s_{n+1}, t_{n+1})) \in \delta$. The definition of $\delta$ implies that there is matrix $M_{n+1} = \left(s' a' \begin{array}{c} t' \end{array} \right) \in \mathcal{M}$ such that $x = s_n t_n a'$ and $s_{n+1} = s_n s'$ and $t_{n+1} = t_n t'$. Hence:

$$M_1 \cdots M_{n+1} = \left(s_n \begin{array}{c} t_n \end{array} a \right) \left(s_n s_{n+1} \begin{array}{c} s_n t_n t' x \end{array} \right) = \left(s_{n+1} \begin{array}{c} t_n t' x + t_{n+1} a \end{array} \right)$$

The other direction (from matrix product to run) is similar. This proves the proposition. ◀

B Proof of Theorem 10

**Theorem 10.** The membership problems for UT$[A_{11} \neq 0]$ and for UT$[A_{22} \neq 0]$ are in PSPACE.

**Proof.** We only give the proof for UT$[A_{22} \neq 0]$; the proof for UT$[A_{11} \neq 0]$ is symmetric. Fix some $T \in UT$ and $\mathcal{M} \subseteq UT[A_{22} \neq 0]$. If $T_{11} \neq 0$, then $T \in \langle UT[A_{11} \neq 0] \cap \mathcal{M} \rangle$ must hold, which by Theorem 6 can be verified in NP, and thus in PSPACE. So let us now assume $T_{11} = 0$. Then we have

$$T = \left(\begin{array}{cc} 0 & T_{12} \\ 0 & T_{22} \end{array}\right) \in \langle \mathcal{M} \rangle$$

$$\Leftrightarrow T = M_1 \cdot A \cdot M_2$$

$$\Leftrightarrow \left(\begin{array}{cc} 0 & T_{12} \\ 0 & T_{22} \end{array}\right) = M_1 \cdot A \cdot M_2 \cdot \left(\begin{array}{c} 0 \\ 1 \end{array}\right) \text{ for some } M_1, M_2 \in \langle \mathcal{M} \rangle, A \in \mathcal{M} \cap \text{UT} [A_{11} = 0].$$

Thus our problem reduces to the following constrained reachability problem: Is $\vec{y} = \left(\begin{array}{c} T_{12} \\ T_{22} \end{array}\right)$ reachable from $\vec{x} = \left(\begin{array}{c} 0 \\ 1 \end{array}\right)$ via a product of matrices from $\mathcal{M}$, such that at least one matrix from UT$[A_{11} = 0]$ occurs in the product? This problem is decidable in PSPACE via a minor modification of the approach outlined in the proof of Theorem 6. The polynomial register machine constructed in the proof of Theorem 6 only needs to additionally track whether a matrix from UT$[A_{11} = 0]$ has been applied. With $R_\delta = (Q, \Delta, \lambda)$ from
the proof of Theorem 6, this can be realized with the modified polynomial register machine $R'_B = (Q', \Delta', \lambda')$ where $Q' = \{0, 1\} \times Q$, $\Delta' = Q' \times Q'$ and $\lambda': Q' \times Q' \to \lambda(Q \times Q)$ is defined minimally such that for every $q, q' \in Q$, every $f_{M, \alpha} \in \lambda((q, q'))$, and every $b \in \{0, 1\}$ the following holds:

$$(b, q) \xrightarrow{f_{M, \alpha}} (b, q') \text{ if } M \in UT[A_{11} \neq 0],$$

$$(b, q) \xrightarrow{f_{M, \alpha}} (1, q') \text{ if } M \in UT[A_{11} = 0].$$

After guessing the matrix sequence $B$ as outlined in the proof of Theorem 6, a nondeterministic Turing machine only needs to verify $(0, (0, 1)) \xrightarrow{\rightarrow_{R'_B}(1, (T_{22}, T_{21}))}$ in order to obtain a positive witness for the constrained reachability problem, which can be done in PSPACE, and the statement follows.

\section*{C Proof of Equivalences in Section 5}

In this section we prove the equivalences $(6) \iff (7)$ and $(7) \iff (8)$ from Section 5. Let us recall the definitions of Section 5:

Fix $M \subseteq UT$, $\vec{x}$, $\vec{y}$. Define $A := M \cap UT[A_{22} = 0]$, $B := M \cap UT[A_{11} = 0]$, $C := (M \setminus (A \cup B))$, $Y := \begin{pmatrix} y_1 & y_2 \\ 0 & 0 \end{pmatrix}$, and $X := \begin{pmatrix} 0 & x_1 \\ 0 & x_2 \end{pmatrix}$.

Further define

$$A' := \begin{cases} A & \text{if } |y_1| = 1, \\ \emptyset & \text{otherwise.} \end{cases}$$

$$B' := \begin{cases} B & \text{if } |x_2| = 1, \\ \emptyset & \text{otherwise.} \end{cases}$$

Then the following equivalences hold:

$\exists M \in \langle M \rangle : \vec{y}^T M \vec{x} \in \{\pm 1\} \iff (6)$

$\exists A \in A \cup \{I\}, B \in B \cup \{I\}, C \in \langle C \rangle : \vec{y}^T \cdot (A \cdot C \cdot B) \cdot \vec{x} \in \{\pm 1\} \iff (7)$

$\begin{pmatrix} 0 & \pm 1 \\ 0 & 0 \end{pmatrix} \in \bigcup_{A \in A' \cup \{Y\}, B \in B' \cup \{X\}} \langle C \cup \{A, B\} \rangle.$

$\exists M \in \langle M \rangle : \vec{y}^T M \vec{x} \in \{\pm 1\}.$

Proof of $(6) \iff (7)$. The direction $(7) \Rightarrow (6)$ is immediate. Let us now prove $(6) \Rightarrow (7)$. Assume $(6)$:

$\exists M \in \langle M \rangle : \vec{y}^T M \vec{x} \in \{\pm 1\}.$

Fix $M$. If $M \in \langle C \rangle$, then $(7)$ is directly implied. So let us assume $M \not\in \langle C \rangle$ instead. We only need to consider the case where $M$ can be decomposed into

$$M = M_1 \cdot A \cdot C \cdot B \cdot M_2$$

such that $M_1 \in \langle M \rangle$, $A \in A$, $B \in B$, $C \in C$, and $M_2 \in \langle M \rangle$. The other cases are similar. For every $M \in UT$ there exist $\alpha, \beta \in \mathbb{Z}$ such that $M \cdot A = \alpha A$ and $B \cdot M = \beta B$, and thus we can rewrite $(9)$ to

$$M = \alpha \cdot A \cdot C \cdot B \cdot \beta$$

(10)
for some $\alpha, \beta \in \mathbb{Z}$. Now, by assumption $\vec{y}^T M \vec{x} \in \{\pm 1\}$ holds, thus we must have $|\alpha| = |\beta| = 1$ in (10). From this we obtain $\vec{y}^T (A \cdot C \cdot B) \vec{x} \in \{\pm 1\}$. Hence (7) holds. This proves the implication.

**Proof of (7) $\Rightarrow$ (8).** Let us first prove the implication (7) $\Rightarrow$ (8). To this end, assume that (7) holds:

$$\exists A \in A \cup \{I\}, B \in B \cup \{I\}, C \in \langle C \rangle : \vec{y}^T \cdot (A \cdot C \cdot B) \cdot \vec{x} \in \{\pm 1\}$$

Fix $A, B, C$. If $A = B = I$, then (8) is immediate via

$$\vec{y}^T \cdot C \cdot \vec{x} \in \{\pm 1\} \iff (X \cdot C \cdot Y) = \begin{pmatrix} 0 & \pm 1 \\ 0 & 0 \end{pmatrix}.$$  

So let us consider the most instructive case where $A \in A \setminus \{I\}$ and $B \in A \setminus \{I\}$ holds – the remaining cases can be proved by analogous reasoning. In this case, we obtain from (7) the equality:

$$Y \cdot A \cdot C \cdot B \cdot X = y_1 \cdot A \cdot C \cdot B \cdot x_2 = \begin{pmatrix} 0 & \pm 1 \\ 0 & 0 \end{pmatrix}$$  

(11)

From (11) we obtain $|y_1| = |x_2| = 1$, and in particular $A' = A$ and $B' = B$, and thus:

$$A \cdot C \cdot B = \begin{pmatrix} 0 & \pm 1 \\ 0 & 0 \end{pmatrix}$$  

(12)

where $A \in A' = A$ and $B \in B' = B$. This implies (8), and we are done showing the implication (7) $\Rightarrow$ (8).

Now let us prove the implication (8) $\Rightarrow$ (7). Assume (8):

$$\begin{pmatrix} 0 & \pm 1 \\ 0 & 0 \end{pmatrix} \in \bigcup_{A \in A' \cup \{Y\}, B \in B' \cup \{X\}} \langle C \cup \{A, B\} \rangle.$$  

(13)

By the argument given in the proof of (7) $\Rightarrow$ (6), (13) entails:

$$\begin{pmatrix} 0 & \pm 1 \\ 0 & 0 \end{pmatrix} = A \cdot C \cdot B$$  

for some $C \in \langle C \rangle$.  

(14)

Now, if $A = Y$ and $B = X$, (7) follows. In the other cases $A'$ or $B'$ is non-empty, which by definition of $A'$ and $B'$ means that $|y_1| = 1$ or $|x_1| = 1$ must hold, which in turn implies that $Y \cdot A = \pm A$ or $B \cdot X = \pm B$. Let us consider the most instructive case where $A \neq Y$ and $B \neq X$; the other cases are similar. Then by the previous remarks, we have:

$$X \cdot A \cdot C \cdot B \cdot Y = \pm A \cdot C \cdot \pm B = \begin{pmatrix} 0 & \pm 1 \\ 0 & 0 \end{pmatrix}.$$  

This entails (7), and we are done.
