Abstract

Analogs of the classical Sylvester theorem have been known for matrices with entries in noncommutative algebras including the quantized algebra of functions on $GL_N$ and the Yangian for $\mathfrak{gl}_N$. We prove a version of this theorem for the twisted Yangians $Y(\mathfrak{g}_N)$ associated with the orthogonal and symplectic Lie algebras $\mathfrak{g}_N = \mathfrak{o}_N$ or $\mathfrak{sp}_N$. This gives rise to representations of the twisted Yangian $Y(\mathfrak{g}_{N-M})$ on the space of homomorphisms $\text{Hom}_{\mathfrak{g}_M}(W, V)$, where $W$ and $V$ are finite-dimensional irreducible modules over $\mathfrak{g}_M$ and $\mathfrak{g}_N$, respectively. In the symplectic case these representations turn out to be irreducible and we identify them by calculating the corresponding Drinfeld polynomials. We also apply the quantum Sylvester theorem to realize the twisted Yangian as a projective limit of certain centralizers in universal enveloping algebras.
1 Introduction

Let $\mathfrak{g}$ be a complex reductive Lie algebra and $\mathfrak{a} \subset \mathfrak{g}$ a reductive subalgebra. Suppose that $V$ is a finite-dimensional irreducible $\mathfrak{g}$-module and consider its restriction to the subalgebra $\mathfrak{a}$. This restriction is isomorphic to a direct sum of irreducible finite-dimensional $\mathfrak{a}$-modules $W_\mu$ with certain multiplicities $m_\mu$:

$$V|_\mathfrak{a} \cong \bigoplus_\mu m_\mu W_\mu.$$  

If each $W_\mu$ is provided with a basis and the decomposition is multiplicity-free (i.e., $m_\mu \leq 1$ for all $\mu$) then it can be used to get a basis of $V$ as the union of the bases of the spaces $W_\mu$ which occur in the decomposition. This observation played a key role in the construction of the Gelfand–Tsetlin bases for the representations of the general linear and orthogonal Lie algebras. Although the restriction of an irreducible finite-dimensional representation of the symplectic Lie algebra $\mathfrak{sp}_{2n}$ to the subalgebra $\mathfrak{sp}_{2n-2}$ is not multiplicity-free in general, this approach can be extended to the symplectic case with the use of the isomorphism

$$V \cong \bigoplus_\mu U_\mu \otimes W_\mu, \quad (1.1)$$

where

$$U_\mu = \text{Hom}_\mathfrak{a}(W_\mu, V), \quad \dim U_\mu = m_\mu.$$  

The space $U_\mu$ is an irreducible module over the algebra $C(\mathfrak{g}, \mathfrak{a}) = U(\mathfrak{g})^\mathfrak{a}$, the centralizer of $\mathfrak{a}$ in the universal enveloping algebra $U(\mathfrak{g})$; see e.g. Dixmier [2, Section 9.1]. Now, if some bases of the spaces $U_\mu$ and $W_\mu$ are given then the decomposition (1.1) yields the natural tensor product basis of $V$. The general difficulty of this approach is the complicated structure of the algebra $C(\mathfrak{g}, \mathfrak{a})$. For each pair of the classical Lie algebras

$$(\mathfrak{g}, \mathfrak{a}) = (\mathfrak{gl}_N, \mathfrak{gl}_M), \quad (\mathfrak{o}_N, \mathfrak{o}_M), \quad (\mathfrak{sp}_N, \mathfrak{sp}_M),$$

(with even $N$ and $M$ in the symplectic case), the centralizer $C(\mathfrak{g}, \mathfrak{a})$ and its representations can be studied with the use of the quantum algebras called Yangians and twisted Yangians. The Yangian $Y(\mathfrak{gl}_N)$ for the general linear Lie algebra $\mathfrak{gl}_N$ is a deformation of the universal enveloping algebra $U(\mathfrak{gl}_N \otimes \mathbb{C}[x])$ in the class of Hopf algebras; see e.g. Drinfeld [3]. The twisted Yangian $Y(\mathfrak{g}_N)$ for the orthogonal or symplectic Lie algebra $(\mathfrak{g}_N = \mathfrak{o}_N$ or $\mathfrak{g}_N = \mathfrak{sp}_N)$ was introduced by Olshanski [18]. This is a subalgebra of $Y(\mathfrak{gl}_N)$ and it can also be presented by generators and defining relations; see also [14]. Finite-dimensional irreducible representations of the algebras $Y(\mathfrak{gl}_N)$ and $Y(\mathfrak{g}_N)$ admit a complete parametrization; see Drinfeld [4] and Tarasov [20] for the Yangian case, and the author’s work [10] for the twisted Yangian case. The Olshanski centralizer construction [18, 19] provides ‘almost surjective’ algebra homomorphisms

$$Y(\mathfrak{gl}_{N-M}) \to C(\mathfrak{gl}_N, \mathfrak{gl}_M), \quad Y(\mathfrak{g}_{N-M}) \to C(\mathfrak{g}_N, \mathfrak{g}_M) \quad (1.2)$$
which allow one to equip the corresponding $C(\mathfrak{g}, \mathfrak{a})$-module $U_\mu$ in (1.1) with the structure of a representation of the Yangian or twisted Yangian, respectively. In particular, in the case $N - M = 2$ this module over the twisted Yangian $Y(\mathfrak{g}_2)$ admits a natural basis which leads to a construction of weight bases of Gelfand–Tsetlin type for the representations of the orthogonal and symplectic Lie algebras; see [13] for a review of these results.

In this paper we exploit the relationship between the (twisted) Yangians and the classical Lie algebras in the reverse direction: we use the weight bases constructed in [13] to investigate the representations of the twisted Yangians $Y(\mathfrak{g}_{N-M})$ emerging from the homomorphisms (1.2).

By the results of [4] and [10] the isomorphism class of each finite-dimensional irreducible representation $V$ of the (twisted) Yangian is determined by its highest weight which is a tuple of formal series over $\mathbb{C}$ in a formal parameter. Moreover, simultaneous multiplication of all components of the highest weight by a fixed invertible formal series corresponds to a representation obtained from $V$ by the composition with a simple automorphism of the (twisted) Yangian. It is natural to combine these representations into a single similarity class. In the case of the Yangian $Y(\mathfrak{gl}_N)$ these similarity classes correspond to finite-dimensional irreducible representations of the Yangian for the special linear Lie algebra $\mathfrak{sl}_N$. Both in the case of the Yangian and the twisted Yangian the similarity classes are parameterized by families of the Drinfeld polynomials $(P_1(u), \ldots, P_r(u))$ with some additional data in the twisted case. Each $P_i(u)$ is a monic polynomial in $u$, and $r$ is the rank of the corresponding Lie algebra.

Given partitions $\lambda = (\lambda_1, \ldots, \lambda_N)$ and $\mu = (\mu_1, \ldots, \mu_M)$, let $V(\lambda)$ and $V(\mu)$ be the finite-dimensional irreducible representation of $\mathfrak{gl}_N$ and $\mathfrak{gl}_M$ with the highest weights $\lambda$ and $\mu$, respectively. The space $\text{Hom}_{\mathfrak{gl}_M}(V(\mu), V(\lambda))$ is then an irreducible representation of the Yangian $Y(\mathfrak{gl}_{N-M})$. Its Drinfeld polynomials were calculated by Nazarov and Tarasov [17]. The result is a simple combinatorial rule which allows one to ‘read off’ each polynomial $P_i(u)$ from the contents of the cells of the skew diagram $\lambda/\mu$. These skew representations of the Yangian (they were called elementary in [17]), may be regarded as building blocks for the class of tame representations. This class is characterized by the property that the action of a natural commutative subalgebra of the Yangian in such a representation is semisimple. By [17], each tame representation is isomorphic to a tensor product of skew representations.

A different way to define the homomorphism (1.2) in the case of $\mathfrak{gl}_N$ is provided by the quantum Sylvester theorem. Recall that the classical Sylvester theorem is the following identity for a numerical $N \times N$ matrix $A = (a_{ij})$:

$$\det B = \det A \cdot \left( a_{m+1, \ldots, N}^{i, m+1, \ldots, N} \right)^{m-1},$$

where $B = (b_{ij})$ is the $m \times m$ matrix formed by the minors $b_{ij} = a_{i, m+1, \ldots, N}^{i, m+1, \ldots, N}$ of $A$. The sequences of top and bottom indices indicate the row and column numbers of the minor, respectively. The most general noncommutative analog of this identity
was given by Gelfand and Retakh in the context of the theory of quasideterminants originated in their work \[6\]; see also \[5\] for a review of this theory. ‘Quantum’ versions of this identity apply to the matrices formed by the generators of certain quantum algebras, and the determinants are replaced by appropriate quantum determinants. In particular, such a version was given by Krob and Leclerc \[8\] for the quantized algebra of functions on $GL_N$. Their approach is also applicable to the Yangian $Y(gl_N)$. A different proof for the Yangian case is given in \[12\] where the corresponding quantum Sylvester theorem was used to give a modified version of the Olshanski centralizer construction. This provided a new definition of the skew representations of the Yangian and the calculation of their Drinfeld polynomials.

In this paper we produce a quantum Sylvester theorem for the twisted Yangian $Y(g_N)$ with the use of the Sklyanin minors of the matrix of generators of $Y(g_N)$. We first obtain the theorem for the extended twisted Yangian $X(g_N)$ (Section 2), following the approach of \[8\]. The twisted Yangian $Y(g_N)$ is a quotient of $X(g_N)$ which yields the corresponding result for $Y(g_N)$ (Section 3). In Section 4 we apply the quantum Sylvester theorem to construct a new homomorphism \[12\] for the twisted Yangian and introduce the corresponding skew representations. We show that in the symplectic case each skew representation is irreducible and calculate its highest weight and the Drinfeld polynomials. The Drinfeld polynomials are found by the following simple combinatorial rule somewhat analogous to the Yangian case \[17\] (see Section 4 below for a detailed formulation). Given a partition $\nu = (\nu_1, \ldots, \nu_n)$ we draw its diagram $\Gamma(\nu)$ as follows. First, place the row with $\nu_n$ unit cells on the plane in such a way that the center of the leftmost cell coincides with the origin. Then place the second row with $\nu_{n-1} - \nu_n$ cells in such a way that the southwest corner of this row coincides with the northeast corner of the first row. Continuing in this manner, we complete this procedure by placing an infinite row of cells in such a way that its southwest corner coincides with the northeast corner of the row with $\nu_1 - \nu_2$ cells. The diagram $\Gamma(\nu)$ is obtained as the union of the rows just placed and their images under the central symmetry with respect to the southwest corner of the first row. The figure below represents the diagram for the partition $\nu = (7, 4)$, where the dot indicates the origin.

To each cell of the diagram we attach its diagonal number, where by diagonals we mean the lines passing northwest-southeast through the integer points of the plane. The line on the figure indicates the 0-th diagonal and the diagonal numbers are consecutive integers increasing from right to left. For any nonnegative integer $p$ denote by $\Gamma(\lambda)^{(p)}$ the diagram $\Gamma(\lambda)$ lifted $p$ units up.
Suppose now that $V(\lambda)$ and $V(\mu)$ are the irreducible finite-dimensional representations of $\mathfrak{sp}_{2n}$ and $\mathfrak{sp}_{2m}$ corresponding to partitions $\lambda$ and $\mu$ having $n$ and $m$ parts, respectively. Then the Drinfeld polynomials $P_1(u), \ldots, P_{n-m}(u)$ for the skew representation $\text{Hom}_{\text{sp}_{2m}}(V(\mu), V(\lambda))$ of the twisted Yangian $Y(\text{sp}_{2n-2m})$ can be calculated by the following rule: all roots of the polynomial $P_k(u)$ are simple and they coincide with the diagonal numbers decreased by 1/2 of the cells of the intersection $\Gamma(\mu) \cap \Gamma(\lambda)^{(k-1)}$ (see Theorem 4.9 and Example 4.10 below).

Finally, in Section 5 we give a realization of the twisted Yangian $Y(\mathfrak{g}_N)$ as a projective limit of centralizers in the universal enveloping algebras. This is a new version of the centralizer construction (cf. [19, 15]) which is based on the quantum Sylvester theorem.

The recent work of Nazarov [16] is also devoted to the skew representations of the twisted Yangians although from a different perspective. He uses the classical Weyl’s approach and gives a realization of the skew representations in the tensor powers of the vector representation by applying certain generalized Young symmetrizers.

## 2 Extended twisted Yangian

We start by stating and proving some auxiliary results about the extended twisted Yangian $X(\mathfrak{g}_N)$; see [14] for more details.

### 2.1 Preliminaries

We shall be considering the orthogonal and symplectic cases simultaneously, unless otherwise stated. Given a positive integer $N$, we number the rows and columns of $N \times N$ matrices by the indices $\{-n, \ldots, -1, 0, 1, \ldots, n\}$ if $N = 2n + 1$, and by $\{-n, \ldots, -1, 1, \ldots, n\}$ if $N = 2n$. Similarly, in the latter case the range of summation indices $-n \leq i, j \leq n$ will usually exclude 0. It will be convenient to use the symbol $\theta_{ij}$ which is defined by

$$\theta_{ij} = \begin{cases} 1 & \text{in the orthogonal case}, \\ \text{sgn } i \cdot \text{sgn } j & \text{in the symplectic case}. \end{cases}$$

Throughout the paper, whenever the double sign $\pm$ or $\mp$ occurs, the upper sign corresponds to the orthogonal case and the lower sign to the symplectic case. By $A \mapsto A^t$ we will denote the matrix transposition such that $(A^t)_{ij} = \theta_{ij} A_{-j,-i}$. Let the $E_{ij}$ denote the standard basis vectors of the general linear Lie algebra $\mathfrak{gl}_N$. These vectors may be also regarded as elements of the universal enveloping algebra $U(\mathfrak{gl}_N)$. For this reason we want to distinguish the $E_{ij}$ from the standard matrix units $e_{ij}$ which are considered as basis elements of the endomorphism algebra End $\mathbb{C}^N$. Introduce the following elements of the Lie algebra $\mathfrak{gl}_N$:

$$F_{ij} = E_{ij} - \theta_{ij} E_{-j,-i}, \quad -n \leq i, j \leq n.$$
The Lie subalgebra $\mathfrak{g}_N$ of $\mathfrak{gl}_N$ spanned by the elements $F_{ij}$ is isomorphic to the orthogonal Lie algebra $\mathfrak{o}_N$ or the symplectic Lie algebra $\mathfrak{sp}_N$ (in the latter case $N$ is even).

The extended twisted Yangian $X(\mathfrak{g}_N)$ corresponding to the Lie algebra $\mathfrak{g}_N$ is the associative algebra with generators $s_{ij}^{(1)}$, $s_{ij}^{(2)}$, ... where $-n \leq i, j \leq n$, subject to the defining relations written in terms of the generating series

$$s_{ij}(u) = \delta_{ij} + s_{ij}^{(1)} u^{-1} + s_{ij}^{(2)} u^{-2} + \cdots \in X(\mathfrak{g}_N)[[u^{-1}]]$$

as follows

$$(u^2 - v^2) [s_{ij}(u), s_{kl}(v)] = (u + v) (s_{kj}(u)s_{il}(v) - s_{kl}(v)s_{ij}(u))$$

$$- (u - v) \left( \theta_{k,-j}s_{i,-k}(u)s_{-j,l}(v) - \theta_{k,-l}s_{k,-i}(v)s_{-l,j}(u) \right)$$

$$+ \theta_{i,-j}(s_{k,-i}(u)s_{-j,l}(v) - s_{k,-l}(v)s_{-j,i}(u)),$$

where $u$ and $v$ denote formal variables. The defining relations can also be presented in a convenient matrix form. Denote by $S(u)$ the $N \times N$ matrix whose $ij$-th entry is $s_{ij}(u)$. We may regard $S(u)$ as an element of the algebra $X(\mathfrak{g}_N)[[u^{-1}]] \otimes \text{End} \mathbb{C}^N$ given by

$$S(u) = \sum_{i,j} s_{ij}(u) \otimes e_{ij},$$

where the $e_{ij}$ denote the standard matrix units. For any positive integer $m$ we shall be using the algebras of the form

$$X(\mathfrak{g}_N)[[u^{-1}]] \otimes \text{End} \mathbb{C}^N \otimes \cdots \otimes \text{End} \mathbb{C}^N, \quad (2.1)$$

with $m$ copies of $\text{End} \mathbb{C}^N$. For any $a \in \{1, \ldots, m\}$ we denote by $S_a(u)$ the matrix $S(u)$ which acts on the $a$-th copy of $\text{End} \mathbb{C}^N$. That is, $S_a(u)$ is an element of the algebra (2.1) of the form

$$S_a(u) = \sum_{i,j} s_{ij}(u) \otimes 1 \otimes \cdots \otimes 1 \otimes e_{ij} \otimes 1 \otimes \cdots \otimes 1,$$

where the $e_{ij}$ belong to the $a$-th copy of $\text{End} \mathbb{C}^N$ and $1$ is the identity matrix. Similarly, if

$$C = \sum_{i,j,k,l} c_{ijkl} e_{ij} \otimes e_{kl} \in \text{End} \mathbb{C}^N \otimes \text{End} \mathbb{C}^N,$$

then for distinct indices $a, b \in \{1, \ldots, m\}$ we introduce the element $C_{ab}$ of the algebra (2.1) by

$$C_{ab} = \sum_{i,j,k,l} c_{ijkl} 1 \otimes 1 \otimes \cdots \otimes 1 \otimes e_{ij} \otimes 1 \otimes \cdots \otimes 1 \otimes e_{kl} \otimes 1 \otimes \cdots \otimes 1,$$
where the $e_{ij}$ and $e_{kl}$ belong to the $a$-th and $b$-th copies of End $\mathbb{C}^N$, respectively. Consider now the permutation operator

$$P = \sum_{i,j} e_{ij} \otimes e_{ji} \in \text{End} \mathbb{C}^N \otimes \text{End} \mathbb{C}^N.$$ 

The rational function $R(u) = 1 - Pu^{-1}$ with values in the tensor product algebra $\text{End} \mathbb{C}^N \otimes \text{End} \mathbb{C}^N$ is called the Yang $R$-matrix. Introduce its transposed $R^t(u)$ by

$$R^t(u) = 1 - Qu^{-1}, \quad Q = \sum_{i,j} \theta_{ij} e_{j,-i} \otimes e_{ji}. \quad (2.2)$$

The defining relations for the extended twisted Yangian $X(g_N)$ are equivalent to the quaternary relation

$$R(u - v)S_1(u)R^t(-u - v)S_2(v) = S_2(v)R^t(-u - v)S_1(u)R(u - v). \quad (2.3)$$

Let $u_1, \ldots, u_k$ be independent variables. For $k \geq 2$ consider the rational function $R(u_1, \ldots, u_k)$ with values in $(\text{End} \mathbb{C}^N)^\otimes k$ defined by

$$R(u_1, \ldots, u_k) = (R_{k-1,k})(R_{k-2,k}R_{k-2,k-1}) \cdots (R_{1k} \cdots R_{12}),$$

where we abbreviate $R_{ij} = R_{ij}(u_i - u_j)$.

Set $S_i = S_i(u_i), \quad 1 \leq i \leq k$ and $R_{ij}^t = R_{ij}^t(-u_i - u_j), \quad 1 \leq i < j \leq k$.

For an arbitrary permutation $(p_1, \ldots, p_k)$ of the numbers $1, \ldots, k$, we abbreviate

$$\langle S_{p_1}, \ldots, S_{p_k} \rangle = S_{p_1}(R_{p_1p_2}^t \cdots R_{p_1p_k}^t)S_{p_2}(R_{p_2p_3}^t \cdots R_{p_2p_k}^t) \cdots S_{p_k}.$$

The identity

$$R(u_1, \ldots, u_k)\langle S_1, \ldots, S_k \rangle = \langle S_k, \ldots, S_1 \rangle R(u_1, \ldots, u_k) \quad (2.4)$$

can be deduced from the quaternary relation $[14]$; see [14] Proposition 4.2. Now specialize the variables $u_i$ by setting

$$u_i = u - i + 1, \quad i = 1, \ldots, k. \quad (2.5)$$

It is well known that under this specialization, $R(u_1, \ldots, u_k)$ coincides with the anti-symmetrization operator $A_k$ on $(\mathbb{C}^N)^\otimes k$, where

$$A_k = \sum_{\sigma \in \mathfrak{S}_k} \text{sgn} \sigma \cdot P_\sigma,$$

and $P_\sigma$ denotes the image of $\sigma \in \mathfrak{S}_k$ under the natural action of $\mathfrak{S}_k$ on $(\mathbb{C}^N)^\otimes k$; see e.g. [14] Proposition 2.3. Hence specializing the variables in (2.4) we get

$$A_k \langle S_1, \ldots, S_k \rangle = \langle S_k, \ldots, S_1 \rangle A_k.$$
This element of the tensor product \( X(\mathfrak{g}_N)[[u^{-1}]] \otimes (\text{End} \mathbb{C}^N)^{\otimes k} \) can be written as
\[
\sum s_{b_1 \cdots b_k}^{a_1 \cdots a_k}(u) \otimes e_{a_1 b_1} \otimes \cdots \otimes e_{a_k b_k},
\]
summed over the indices \( a_i, b_i \in \{-n, \ldots, n\} \). We also set \( s_{b_i}^a(u) = s_{ab}(u) \). We call the elements \( s_{b_1 \cdots b_k}^{a_1 \cdots a_k}(u) \) of \( X(\mathfrak{g}_N)[[u^{-1}]] \) the Sklyanin minors of the matrix \( S(u) \).

Clearly, the Sklyanin minors are skew-symmetric with respect to permutations of the upper indices and of the lower indices:
\[
s_{b_1 \cdots b_k}^{a_1 \cdots a_k}(u) = sgn \cdot s_{b_1 \cdots b_k}^{a_1 \cdots a_k}(u) \quad \text{and} \quad s_{b_1(1) \cdots b_k(k)}^{a_1 \cdots a_k}(u) = sgn \cdot s_{b_1 \cdots b_k}^{a_1 \cdots a_k}(u)
\]
for any \( \sigma \in \mathfrak{S}_k \).

**Proposition 2.1.** We have the relations
\[
(u^2 - v^2)[s_{pq}(u), s_{b_1 \cdots b_k}^{a_1 \cdots a_k}(v)]
\]
\[
= (u + v) \sum_{i=1}^k \left( s_{a_i q}(u) s_{b_1 \cdots b_k}^{a_1 \cdots q \cdots a_k}(v) - s_{b_1 \cdots q \cdots a_k}(u) s_{b_1 \cdots b_k}^{a_1 \cdots q \cdots a_k}(v) \right)
\]
\[
- (u - v) \sum_{i=1}^k \left( \theta_{a_i, -q} s_{b_i, -a_i}(u) s_{b_1 \cdots b_k}^{a_1 \cdots q \cdots a_k}(v) - \theta_{p, -b_i} s_{b_1 \cdots b_k}^{a_1 \cdots q \cdots a_k}(u) s_{b_1 \cdots b_k}^{a_1 \cdots -a_k}(v) \right)
\]
\[
+ \theta_{p, -q} \sum_{i=1}^k (s_{a_i, -p}(u) s_{b_1 \cdots b_k}^{a_1 \cdots q \cdots a_k}(v) - s_{b_1 \cdots -p \cdots a_k}(u) s_{b_1 \cdots b_k}^{a_1 \cdots q \cdots a_k}(v))
\]
\[
+ \sum_{i \neq j} (\theta_{a_i, -q} s_{a_i, -a_j}(u) s_{b_1 \cdots b_k}^{a_1 \cdots -q \cdots a_k}(v) - \theta_{p, -a_j} s_{b_1 \cdots b_k}^{a_1 \cdots a_k}(u) s_{b_1 \cdots b_k}^{a_1 \cdots -q \cdots a_k}(v))
\]
where in the Sklyanin minors the indices \( p \) and \( q \) replace \( a_i \) and \( b_i \), respectively, in the first sum; the indices \( -q \) and \( -p \) replace \( a_i \) and \( b_i \), respectively, in the second and third sums; in the fourth sum \( p \) and \( -q \) replace \( a_i \) and \( a_j \), respectively, and \( -p \) and \( q \) replace \( b_i \) and \( b_j \), respectively.

**Proof.** By (2.4), we have the relation
\[
R(u, v, v - 1, \ldots, v - k + 1) \langle S_0, \ldots, S_k \rangle = \langle S_k, \ldots, S_0 \rangle R(u, v, v - 1, \ldots, v - m + 1),
\]
where we have used an extra copy of the algebra \( \text{End} \mathbb{C}^N \) labelled by \( 0 \) and the parameters are specialized as follows
\[
u_0 = u, \quad \text{and} \quad u_i = v - i + 1 \quad \text{for} \quad i = 1, \ldots, k.
\]
Then one easily verifies (see e.g. [12]) that the product of \( R \)-matrices in (2.1) simplifies to
\[
R(u, v, v - 1, \ldots, v - k + 1) = A_k \left( 1 - \frac{1}{u - v} \right) \left( P_{01} + \cdots + P_{0k} \right).
\]
Applying the transposition over the zeroth copy of $\text{End } \mathbb{C}^N$ and replacing $u$ by $-u$ we also deduce that

$$A_k R_{01}^0 \cdots R_{0k}^k = A_k \left( 1 + \frac{1}{u+v} (Q_{01} + \cdots + Q_{0k}) \right).$$ \hspace{1cm} (2.7)

Hence (2.6) takes the form

$$\left( 1 - \frac{1}{u-v}(P_{01} + \cdots + P_{0k}) \right) S_0(u) \left( 1 + \frac{1}{u+v} (Q_{01} + \cdots + Q_{0k}) \right) A_k (S_1, \ldots, S_k)$$

$$= (S_k, \ldots, S_1) A_k \left( 1 + \frac{1}{u+v} (Q_{01} + \cdots + Q_{0k}) \right) S_0(u) \left( 1 - \frac{1}{u-v}(P_{01} + \cdots + P_{0k}) \right).$$

It remains to apply both sides to the vector $e_q \otimes e_{b_1} \otimes \cdots \otimes e_{b_k}$ and compare the coefficients at the vector $e_p \otimes e_{a_1} \otimes \cdots \otimes e_{a_k}$, where the $e_i$ denote the canonical basis vectors of $\mathbb{C}^N$.

**Corollary 2.2.** Suppose that for some indices $i, j, l, m \in \{1, \ldots, k\}$ we have $a_i = -b_l$ and $b_j = -a_m$. Then

$$[s_{a_i b_j}(u), s_{a_1 \cdots a_k}(v)] = 0.$$

**Proof.** By the skew-symmetry property, the Sklyanin minor is zero if it has two repeated upper or lower indices. Hence we may assume that $i = m$ if and only if $j = l$. Suppose first that $i \neq m$. Then using the skew-symmetry of Sklyanin minors, we derive from Proposition 2.1 that

$$(u-v-1)(u+v+1) [s_{a_i b_j}(u), s_{a_1 \cdots a_k}(v)] = \theta_{a_i, -b_j} [s_{-b_j, -a_i}(u), s_{a_1 \cdots a_k}(v)].$$

The same relation holds with $i$ and $j$ replaced by $m$ and $l$, respectively, which proves the claim in the case under consideration. If $a_i = -b_j$ then Proposition 2.1 immediately gives

$$(u-v-1)(u+v+1) [s_{a_i b_j}(u), s_{a_1 \cdots a_k}(v)] = 0,$$

completing the proof.

The series

$$\text{sdet } S(u) = s_{-n \cdots -n}(u) \in \text{X}(g_N)[[u^{-1}]]$$

is called the **Sklyanin determinant** of the matrix $S(u)$. Corollary 2.2 implies that all the coefficients of this series belong to the center of the algebra $\text{X}(g_N)$; see also [14, Theorem 4.8] for a slightly different proof.

The matrix $S(u)$ is invertible and we shall denote by $S^{-1}(u)$ the inverse matrix. The mapping

$$\varphi_N : S(u) \mapsto S^{-1}(-u - N/2)$$ \hspace{1cm} (2.8)

is a homomorphism on the algebra $\text{X}(g_N)$.
defines an involutive automorphism of the algebra $X(\mathfrak{g}_N)$; see [14, Proposition 6.5].

The Sklyanin comatrix $\hat{S}(u)$ is defined by the relation

$$\hat{S}(u) S(u - N + 1) = \text{sdet} S(u). \tag{2.9}$$

Due to (2.8), the mapping

$$S(u) \mapsto \hat{S}(-u + N/2 - 1) \tag{2.10}$$

defines a homomorphism of $X(\mathfrak{g}_N)$ into itself.

We shall also use the auxiliary minors $s_{b_1 \ldots b_{k-1},c}^{a_1 \ldots a_k}(u) \in X(\mathfrak{g}_N)[[u^{-1}]]$ defined by

$$A_k \langle S_1, \ldots, S_{k-1} \rangle R_{1k}^t \cdots R_{k-1,k}^t = \sum_{a_i, b_i, c} \hat{s}_{b_1 \ldots b_{k-1},c}^{a_1 \ldots a_k}(u) \otimes e_{a_1 b_1} \otimes \cdots \otimes e_{a_{k-1} b_{k-1}} \otimes e_{a_k c}, \tag{2.11}$$

summed over $a_i, b_i, c \in \{ -n, \ldots, n \}$. Since

$$A_k \langle S_1, \ldots, S_{k-1} \rangle R_{1k}^t \cdots R_{k-1,k}^t S_k = A_k \langle S_1, \ldots, S_k \rangle,$$

we immediately obtain the relation

$$s_{b_1 \ldots b_k}^{a_1 \ldots a_k}(u) = \sum_{c=-n}^{n} \hat{s}_{b_1 \ldots b_{k-1},c}^{a_1 \ldots a_k}(u) s_c b_k(u - k + 1). \tag{2.12}$$

We obviously have

$$\hat{s}_{b_1 \ldots b_{k-1},c}^{a_1 \ldots a_k}(u) = \text{sgn} \sigma \cdot \hat{s}_{b_1 \ldots b_{k-1},c}^{a_1 \ldots a_k}(u)$$

for any $\sigma \in \mathfrak{S}_k$. Also,

$$\hat{s}_{b_1 \ldots b_{k-1},c}^{a_1 \ldots a_k}(u) = \text{sgn} \sigma \cdot \hat{s}_{b_1 \ldots b_{k-1},c}^{a_1 \ldots a_k}(u)$$

for any $\sigma \in \mathfrak{S}_{k-1}$; see [9]. Furthermore, it is straightforward to obtain the following property of the auxiliary minors from their definition (cf. [9, Proposition 4.4]): if $c \notin \{a_1, \ldots, a_{k-1}\}$ and $c \notin \{-b_1, \ldots, -b_{k-1}\}$ then

$$\hat{s}_{b_1 \ldots b_{k-1},c}^{a_1 \ldots a_k}(u) = 0 \tag{2.13}$$

if $c \neq a_k$, while

$$\hat{s}_{b_1 \ldots b_{k-1},c}^{a_1 \ldots a_{k-1},c}(u) = s_{b_1 \ldots b_{k-1}}^{a_1 \ldots a_{k-1}}(u). \tag{2.14}$$

Set $(a_1, \ldots, a_N) = (-n, \ldots, n)$. Then the matrix elements $\hat{s}_{a_i a_j}(u)$ of the Sklyanin comatrix $\hat{S}(u)$ are given by

$$\hat{s}_{a_i a_j}(u) = (-1)^{N-i} s_{a_1 \ldots a_i \ldots a_N, a_j}(u), \tag{2.15}$$

where the hat on the right hand side indicates the index to be omitted; see [9, Section 6].
2.2 Sylvester theorem

We shall need some complementary minor identities for the algebra $X(\mathfrak{g}_N)$; cf. \cite{11}, \cite{8}. Fix a nonnegative integer $m < n$ and set $M = 2m$ or $M = 2m + 1$ if $N = 2n$ or $N = 2n + 1$, respectively, so that $N - M = 2n - 2m$. Set $\mathcal{B} = \{-m, \ldots, m\}$ and denote by $\mathcal{A}$ the complement of the subset $\mathcal{B}$ in the set $\{-n, \ldots, n\}$ so that the elements of the set $\mathcal{A}$ are

$$(a_1, \ldots, a_{N-M}) = (-n, \ldots, -m - 1, m + 1, \ldots, n).$$

The images of some Sklyanin minors and auxiliary minors with respect to the automorphism $\varpi_N$ defined in (2.8) are provided by the following.

**Proposition 2.3.** We have the identities

$$s\text{det} S(u) \cdot \varpi_N \left( s_{a_1 \cdots a_{N-M}}^{a_1 \cdots a_{N-M}} (-u + N/2 - 1) \right) = s_{-m \cdots m}(-u),$$

(2.16)

and

$$s\text{det} S(u) \cdot \varpi_N \left( s_{a_1 \cdots a_{N-M}}^{a_1 \cdots a_{N-M}} (-u + N/2 - 1) \right)
= (-1)^{N-M-i} s_{-m \cdots m, a_i}(-u),$$

(2.17)

for any $i, j \in \{1, \ldots, N - M\}$. In particular,

$$s\text{det} S(u) \cdot \varpi_N (s\text{det} (-u + N/2 - 1)) = 1.$$  
(2.18)

**Proof.** By definition of the Sklyanin determinant,

$$A_N \langle S_1, \ldots, S_N \rangle = A_N s\text{det} S(u).$$

(2.19)

This implies the relation

$$A_N \langle S_1, \ldots, S_M \rangle \prod_{i=1, \ldots, M} (R_{i,i+1}^t - R_{i,i+1}^t)$$

$$= A_N s\text{det} S(u) S_{N}^{-1} (R_{N-1,N}^t)^{-1} S_{N-1}^{-1} \cdots (R_{M+1,M+2}^t)^{-1} S_{M+1}^{-1}.$$

Note that since $Q^2 = NQ$ we find from (2.2) that

$$R_i^t(-u) = R_i^t(-u + N).$$

Therefore, the right hand side can be written as

$$A_N s\text{det} S(u) S_{N}^\circ R_{N-1,N}^\circ S_{N-1}^\circ \cdots R_{M+1,M+2}^\circ S_{M+1}^\circ,$$

where we have used the notation $S^\circ(u) = \varpi_N(S(u))$ and

$$S_i^\circ = S_i^\circ(u_i^\circ), \quad R_{ij}^\circ = R_{ij}^t(-u_i^\circ - u_j^\circ), \quad u_i^\circ = -u_i - N/2 \quad (2.20)$$

which are the images of $m \cdots m$. \hfill $\Box$
with \( u_i = u - i + 1 \) for \( i = 1, \ldots, N \). Now apply both sides to the basis vector

\[
v = e_{-m} \otimes \cdots \otimes e_m \otimes e_{a_1} \otimes \cdots \otimes e_{a_{N-M}},
\]

where the \( e_r \) denote the canonical basis vectors of \( \mathbb{C}^N \). Comparing the coefficients at the vector \( A_N v \) we come to (2.10).

The proof of (2.17) is similar with the use of the relation

\[
A_N \langle S_1, \ldots, S_{M+1} \rangle \prod_{i=1,\ldots,M} (R_{i,M+1}^i \cdots R_{iN}^i)
= A_N \sdet S(u) S_N^{-1}(R_{N-1,N}^1) \cdots S_{M+2}^{-1}(R_{M+1,N}^1) \cdots (R_{M+1,M+2}^1)^{-1}
\]

implied by (2.19). Using (2.20) we can rewrite the right hand side as

\[
A_N \sdet S(u) S_N^a R_{N-1,N}^b S_N^{-1} \cdots S_{M+2}^a R_{M+1,N}^{a+1} \cdots R_{M+1,M+2}^{a+1}.
\]

The proof is completed by applying both sides to the vector

\[
v_{ij} = e_{-m} \otimes \cdots \otimes e_m \otimes e_{a_1} \otimes \cdots \otimes e_{a_i} \otimes \cdots \otimes e_{a_{N-M}}
\]

and comparing the coefficients at the vector \( A_N v_{11} \).

It follows from the defining relations for the extended twisted Yangian that the subalgebra of \( X(\mathfrak{g}_N) \) generated by the elements \( s^{(r)}_{ij} \) with \( i, j \in B \) can be regarded as a natural homomorphic image of the extended twisted Yangian \( X(\mathfrak{g}_M) \). The homomorphism takes the generators \( s^{(r)}_{ij} \) of \( X(\mathfrak{g}_M) \) to the elements of \( X(\mathfrak{g}_N) \) with the same name. We let \( X(\mathfrak{g}_{N-M}) \) denote the extended twisted Yangian whose generator series \( s_{ab}(u) \) are enumerated by elements \( a, b \in A \). The mapping \( v : X(\mathfrak{g}_{N-M}) \rightarrow X(\mathfrak{g}_N) \) which sends \( s_{ab}(u) \) to the series with the same name in \( X(\mathfrak{g}_N) \) is an algebra homomorphism. Following [1] consider the homomorphism \( \vartheta : X(\mathfrak{g}_{N-M}) \rightarrow X(\mathfrak{g}_N) \) defined as the composition

\[
\vartheta = \varpi_N \circ v \circ \varpi_{N-M}.
\]

Its action on the generators of \( X(\mathfrak{g}_{N-M}) \) can be described with the use of the Gelfand–Retakh quasideterminants [6, 7]. Given an arbitrary \( N \times N \) matrix \( X = (x_{ij}) \) over a ring with 1, denote by \( X^{ij} \) the matrix obtained from \( X \) by deleting the \( i \)-th row and \( j \)-th column. Suppose that the matrix \( X^{ij} \) is invertible. The \( ij \)-th quasideterminant of \( X \) is defined by the formula

\[
|X|_{ij} = x_{ij} - \sum_{k \neq j, l \neq i} x_{ik} (X^{ij})^{-1}_{kl} x_{lj}.
\]

In a more graphic fashion, the quasideterminant \( |X|_{ij} \) is denoted by boxing the entry \( x_{ij} \). The following proposition is proved in the same way as its Yangian counterpart; see [1] Lemma 4.2.]
Proposition 2.4. For any $1 \leq i, j \leq N - M$, we have

$$\vartheta : s_{a_i, a_j}(u + M/2) \mapsto \begin{vmatrix} s_{-m, -m}(u) & \cdots & s_{-m, m}(u) & s_{-m, a_j}(u) \\ \vdots & \ddots & \vdots & \vdots \\ s_{m, -m}(u) & \cdots & s_{m, m}(u) & s_{m, a_j}(u) \\ s_{a_i, -m}(u) & \cdots & s_{a_i, m}(u) & s_{a_i, a_j}(u) \end{vmatrix}.$$ 

We shall need an expression for the image of $s_{a_i, a_j}(u)$ in terms of Sklyanin minors.

Proposition 2.5. For any $1 \leq i, j \leq N - M$, we have

$$\vartheta : s_{a_i, a_j}(u) \mapsto \left[ s_{-m, -m}(u + M/2) \right]^{-1} s_{-m, -m, a_i}(u + M/2).$$

Proof. Considering (2.17) as a relation in the algebra $X(\mathfrak{g}_{N-M})$ by replacing $N$ with $N - M$ and replacing $M$ with 0, we get

$$s^{a_1 \cdots a_{N-M}}(u) \cdot \varpi_{N-M} \left( s^{a_1 \cdots a_{N-M}}(-u + n - m - 1) \right) = (-1)^{N-M-i} s_{a_i, a_j}(u).$$

Now apply $\varpi_{N-M}$ to both sides and use (2.17) to obtain

$$\varpi_{N-M} : s_{a_i, a_j}(u) \mapsto (-1)^{N-M-i} \left[ s^{a_1 \cdots a_{N-M}}(-u + n - m - 1) \right]^{-1} \times s^{a_1 \cdots a_{N-M}}(-u + n - m - 1).$$

Next apply the homomorphism $\vartheta$ and observe that the images of the Sklyanin minors and auxiliary minors occurring in this expression coincide with the respective minors in the algebra $X(\mathfrak{g}_N)$. Indeed, we have the following identity analogous to (2.17) which is verified in the same way:

$$A_{k-1} R^i_{1k} \cdots R^i_{k-1,k} = A_{k-1} \left( 1 + \frac{Q_{1k} + \cdots + Q_{k-1,k}}{2u - k + 1} \right). \tag{2.23}$$

Therefore the left hand side of (2.21) can be written as

$$A_k S_1 \left( 1 + \frac{Q_{12}}{2u - 1} \right) S_2 \left( 1 + \frac{Q_{13} + Q_{23}}{2u - 2} \right) \cdots S_{k-1} \left( 1 + \frac{Q_{1k} + \cdots + Q_{k-1,k}}{2u - k + 1} \right).$$

If we now put $k = N - M$ and apply this operator to the vector

$$e_{a_1} \otimes \cdots \otimes e_{a_i} \otimes \cdots \otimes e_{a_{N-M}} \otimes e_{a_j}$$

then the coefficient at the vector $e_{a_1} \otimes \cdots \otimes e_{a_{N-M}}$ will be an expression involving only the entries $s_{a_b}(u)$ of the matrix $S(u)$ with $a, b \in A$. This proves the claim for the auxiliary minors. The argument for the Sklyanin minors is the same.

Finally, the calculation of the image of $s_{a_i, a_j}(u)$ under $\vartheta$ is completed by the application of $\varpi_N$ with the use of (2.11) and (2.17) for the algebra $X(\mathfrak{g}_N)$. \(\square\)
For any elements \(a, b \in A\) introduce the Sklyanin minors
\[
s_{ab}^x(u) = s_{-m \cdots -m, a}^x (u + M/2) \tag{2.24}
\]
and denote by \(S_{ab}^x(u)\) the \((N - M) \times (N - M)\) matrix whose \(ab\)-entry is \(s_{ab}^x(u)\). Also, denote by \(S_{BB}(u)\) the submatrix of \(S(u)\) whose rows and columns are numbered by the elements of \(B\).

The following is a version of the quantum Sylvester theorem for the extended twisted Yangian \(X(\mathfrak{g}_N)\); cf. [6], [8], [12].

**Theorem 2.6.** The mapping
\[
s_{ab}(u) \mapsto s_{ab}^x(u) \tag{2.25}
\]
defines an algebra homomorphism \(X(\mathfrak{g}_{N-M}) \to X(\mathfrak{g}_N)\). Moreover,
\[
\text{sdet } S_{ab}^x(u) = \text{sdet } S_{BB}(u + M/2) \times \text{sdet } S_{BB}(u + M/2 - 1) \cdots \text{sdet } S_{BB}(u + M/2 - N + M + 1).
\]

**Proof.** By Proposition 2.5, we have
\[
\vartheta : s_{ab}(u) \mapsto [\text{sdet } S_{BB}(u + M/2)]^{-1} \cdot s_{ab}^x(u). \tag{2.26}
\]
As we observed in the proof of Proposition 2.5 the expansion of \(\text{sdet } S_{BB}(u)\) only contains the series \(s_{ij}(u)\) with \(i, j \in \{-m, \ldots, m\}\) (and with some shifts in \(u\)). Hence, by Corollary 2.2 the series \(\text{sdet } S_{BB}(u)\) commutes with \(s_{ab}^x(u)\) for any \(a, b \in A\). Since \(\vartheta\) preserves the defining relations of the extended twisted Yangian, we can conclude that the assignment (2.25) defines a homomorphism.

Furthermore, applying (2.18) and (2.16), we deduce
\[
\vartheta : s_{a_{1} \cdots a_{N-M}}(u) \mapsto [\text{sdet } S_{BB}(u + M/2)]^{-1} \cdot \text{sdet } S(u + M/2).
\]

Now we calculate this image in a different way and compare the results. The expansion of the Sklyanin minor \(s_{a_{1} \cdots a_{N-M}}(u)\) has the form of a linear combination of the products
\[
s_{b_{1}c_{1}}(u) \cdots s_{b_{N}c_{N}}(u - N + M + 1), \quad b_{i}, c_{i} \in A,
\]
the coefficients being rational functions in \(u\). Using the relation (2.26) we derive the desired formula.

Denote by \(\hat{\sigma}_{ab}(u)\) the entries of the Sklyanin comatrix corresponding to the matrix \(S_{ab}^x(u)\).

**Proposition 2.7.** For any \(a, b \in A\) we have the relation
\[
\hat{\sigma}_{ab}(u) = \hat{s}_{ab}(u + M/2) \times \text{sdet } S_{BB}(u + M/2 - 1) \cdots \text{sdet } S_{BB}(u + M/2 - N + M + 2).
\]
Proof. We use the same argument as in the proof of Theorem 2.6. Let us calculate the image of the auxiliary minor \( \tilde{s}_{a_1 \cdots a_{N-M}}^{a_1 \cdots a_{N-M}, a_j}(u) \) under the map \( \vartheta \) in two different ways; see (2.22). Using (2.17) we get

\[
\varphi_{N-M}(\tilde{s}_{a_1 \cdots a_{N-M}}^{a_1 \cdots a_{N-M}, a_j}(u)) = (-1)^{N-M-i} \left[ s_{a_1 \cdots a_{N-M}}(-u + n - m - 1) \right]^{-1} \cdot s_{a_i a_j}(-u + n - m - 1).
\]

Now apply \( \vartheta \) and \( \varphi \) by using (2.16) and (2.17) to conclude that

\[
\varphi : \tilde{s}_{a_1 \cdots a_{N-M}}^{a_1 \cdots a_{N-M}, a_j}(u) \mapsto \left[ \text{sdet } S_{BB}(u + M/2) \right]^{-1} \cdot \tilde{s}_{a_i a_j}(u + M/2).
\]

On the other hand, the expansion of the auxiliary minor \( \tilde{s}_{a_1 \cdots a_{N-M}}^{a_1 \cdots a_{N-M}, a_j}(u) \) in terms of the matrix elements has the form of a linear combination of products

\[
s_{b_1 c_1}(u) s_{b_2 c_2}(u - 1) \cdots s_{b_{N-1} c_{N-1}}(u - N + 2), \quad b_i, c_i \in \{1, \ldots, N\},
\]

the coefficients being rational functions in \( u \). The proof is completed by the application of (2.26).

Interchanging the roles of the sets \( \mathcal{A} \) and \( \mathcal{B} \) in the above arguments one can easily derive the corresponding dual versions of Theorem 2.6 and Proposition 2.7. Here we only record the counterpart of the first part of Theorem 2.6 which will be used below.

Proposition 2.8. The mapping

\[
s_{ij}(u) \mapsto g(u) s_{ij}(u)
\]

defines an algebra homomorphism \( X(\mathfrak{g}_M) \to X(\mathfrak{g}_N) \).

3 Sylvester theorem for the twisted Yangian

The twisted Yangian \( Y(\mathfrak{g}_N) \) corresponding to the Lie algebra \( \mathfrak{g}_N \) is the quotient of the extended twisted Yangian \( X(\mathfrak{g}_N) \) by the following symmetry relation

\[
\theta_{ij}s_{-j,-i}(-u) = s_{ij}(u) \pm s_{ij}(u) - s_{ij}(-u) \quad \frac{2u}{2u},
\]

or, in the matrix form,

\[
S'(u) = S(u) \pm \frac{S(u) - S(-u)}{2u}.
\]

From now on, we shall mainly work with the twisted Yangian and so we keep the same notation \( s_{ij}^{(r)} \) for the generators of the algebra \( Y(\mathfrak{g}_N) \). Note that for any even series \( g(u) \in 1 + \mathbb{C}[[u^{-2}]]u^{-2} \) the mapping

\[
s_{ij}(u) \mapsto g(u) s_{ij}(u)
\]
defines an automorphism of \( Y(\mathfrak{g}_N) \).

As we shall see below, the homomorphism of Theorem \ref{thm:homomorphism} respects the symmetry relation in the orthogonal case, while in the symplectic case a minor correction is needed to obtain a corresponding homomorphism of the twisted Yangians. In order to treat both cases simultaneously, introduce the following notation

\[
\alpha_p(u) = \begin{cases} 
  1 & \text{in the orthogonal case} \\
  \frac{u + 1/2}{u - p + 1/2} & \text{in the symplectic case.}
\end{cases}
\]

The image of the Sklyanin determinant in the twisted Yangian \( Y(\mathfrak{g}_N) \) acquires the following symmetry property

\[
\alpha_n(u)^{-1} \cdot \text{sdet} S(u) = \alpha_n(-u + N - 1)^{-1} \cdot \text{sdet} S(-u + N - 1), \tag{3.3}
\]

see \cite[Section 4.11]{frt}. Moreover, the mapping

\[
S(u) \mapsto \alpha_n(u) \cdot \tilde{S}(-u + N/2 - 1) \tag{3.4}
\]

defines a homomorphism of \( Y(\mathfrak{g}_N) \) into itself; see \cite[Proposition 2.1]{frt}.

We can now prove a quantum Sylvester theorem for the twisted Yangian \( Y(\mathfrak{g}_N) \). We use the notation of the previous section. In particular, recall that \( s_{ab}^*(u) \) denotes the quantum minor as in \cite{frt} for any \( a, b \in \mathcal{A} \).

**Theorem 3.1.** The mapping

\[
s_{ab}(u) \mapsto \alpha_{-m}(u) s_{ab}^*(u) \tag{3.5}
\]
defines an algebra homomorphism \( Y(\mathfrak{g}_{N-M}) \to Y(\mathfrak{g}_N) \). Moreover,

\[
\text{sdet} \left[ \alpha_{-m}(u) S^*(u) \right] = \alpha(u) \cdot \text{sdet} S(u + M/2) \times \text{sdet} S_{BB}(u + M/2 - 1) \cdots \text{sdet} S_{BB}(u + M/2 - N + M + 1),
\]

where

\[
\alpha(u) = \alpha_{-m}(u) \alpha_{-m}(u - 1) \cdots \alpha_{-m}(u - N + M + 1).
\]

**Proof.** Denote by \( S^*(u) \) the matrix which occurs on the right hand side of (3.4). Then by (3.3) we have

\[
\varpi_N(S(u)) = \frac{\alpha_n(u + N/2)}{c(u + N/2)} \cdot S^*(u),
\]

where we have put \( c(u) = \text{sdet} S(u) \) for brevity. Denote by \( S_{\mathcal{A}_A}^*(u) \) the submatrix of \( S^*(u) \) whose rows and columns are numbered by the elements of \( \mathcal{A} \) and let \( \tilde{s}_{ab}^*(u) \) denote the entries of the Sklyanin comatrix corresponding to \( S_{\mathcal{A}_A}^*(u) \). Using the
definition of the auxiliary minors and applying (2.15) and (2.17), we come to the relation
\[ s_{-m \cdots m, a_i} (u + M/2) = c(u + M/2) \times \prod_{i=1}^{N-M-1} \frac{\alpha_n(-u + n - m + N/2 - i)}{c(-u + n - m + N/2 - i)} \cdot \hat{S}_{a_i}^*(u - u - n - m - 1), \quad (3.6) \]
where we have also used the fact that the coefficients of the Sklyanin determinant are central in the twisted Yangian \( Y(g_N) \). Observe that by (3.3) we have
\[ c(u + M/2) \cdot \alpha_n(-u + n - m + N/2 - 1) = \alpha_n(u + M/2). \]
Therefore, (3.6) takes the form
\[ s_{-m \cdots m, a_i} (u + M/2) = \alpha_n(u - u - n - m - 1), \]
where
\[ \varphi(u) = \prod_{i=2}^{N-M-1} \frac{\alpha_n(-u + n - m + N/2 - i)}{c(-u + n - m + N/2 - i)}. \]
By the symmetry property (3.3) we have \( \varphi(u) = \varphi(-u) \), and so the multiplication of the generator series \( s_{ij}(u) \) by \( \varphi(u) \) preserves the twisted Yangian defining relations. Furthermore, by (3.1), the mapping
\[ s_{ab}(u) \mapsto \alpha_{n-m}(u) \hat{S}_{ab}^*(-u + n - m - 1), \quad a, b \in A \]
preserves the defining relations of \( Y(g_{N-M}) \). Thus, we may conclude that the mapping
\[ s_{ab}(u) \mapsto \alpha_{n-m}(u) \alpha_n(u + M/2)^{-1} s_{-m \cdots m, a_i} (u + M/2) \]
defines a homomorphism \( Y(g_{N-M}) \to Y(g_N) \). To complete the proof, observe that \( \alpha_{n-m}(u) \alpha_n(u + M/2)^{-1} = \alpha_{-m}(u) \).

The formula for the Sklyanin determinant of the matrix \( \alpha_{-m}(u)S^t(u) \) is immediate from Theorem 2.6 and the definition of \( \text{sdet} S^t(u) \).

The corresponding version of Proposition 2.8 for the twisted Yangian has the following form.

**Proposition 3.2.** The mapping
\[ s_{ij}(u) \mapsto \alpha_{m-n}(u) \cdot s_{-n \cdots m-1, i, m+1 \cdots n} (u + n - m), \quad -m \leq i, j \leq m \]
defines an algebra homomorphism \( Y(g_M) \to Y(g_N) \).
Now we shall demonstrate that in the case of the twisted Yangian the entries of the Sklyanin comatrix can be expressed in terms of Sklyanin minors; cf. (2.15). We need the following lemma.

**Lemma 3.3.** For the twisted Yangian $Y(\mathfrak{g}_N)$ we have

$$A_N S_1(u) R^t_{12}(-2u + 1) \cdots R^t_{1N}(-2u + N - 1) = \frac{2u + 1}{2u - 1} A_N S^t_1(-u). \tag{3.7}$$

**Proof.** We have the relation $(N - 1)! A_N = A_N A'_{N-1}$, where $A'_{N-1}$ denotes the anti-symmetrizer corresponding to the subset of indices $\{2, \ldots, N\}$. By (2.7),

$$A'_{N-1} R^t_{12}(-2u + 1) \cdots R^t_{1N}(-2u + N - 1) = A'_{N-1} \left(1 + \sum_{1 \leq i < j \leq N} Q_{ij} \right).$$

Therefore, the left hand side of (3.7) takes the form

$$A_N S_1(u) \left(1 + \sum_{1 \leq i < j \leq N} Q_{ij} \right).$$

Apply this operator to a basis vector

$$v_{ij} = e_{a_j} \otimes e_{a_1} \otimes \cdots \otimes \tilde{e}_{a_i} \otimes \cdots \otimes e_{a_N}, \quad i, j \in \{1, \ldots, N\},$$

where $(a_1, \ldots, a_N) = (-n, \ldots, n)$. The coefficient at $A_N v_{ii}$ will be equal to $s_{a_i a_j}(u)$ if $a_j = -a_i$, and equal to the expression

$$\frac{2u - 1}{2u + 1} s_{a_i a_j}(-u)$$

if $a_j \neq -a_i$. In both cases the coefficient coincides with

$$\frac{2u + 1}{2u - 1} s_{a_i a_j}(-u)$$

due to the symmetry relation (3.1). \qed

As before, we set $(a_1, \ldots, a_N) = (-n, \ldots, n)$.

**Proposition 3.4.** For any $i, j \in \{1, \ldots, N\}$ we have the relation

$$\tilde{s}^t_{a_i a_j}(u) = (-1)^{i+j} \cdot \alpha_{N-1}(u) \cdot s_{a_i \cdots \hat{a}_j \cdots a_N}(-u + N - 2).$$

**Proof.** The relations (2.19) and (2.21) with $M = N - 2$ imply that

$$A_N \langle S_1, \ldots, S_{N-1} \rangle = A_N \tilde{S}_N(u) (R^t_{N-1, N})^{-1} \cdots (R^t_{1, N})^{-1}. \tag{3.8}$$

Using the notation (2.20) and the definition of the matrix $S^*(u)$ we can write $\tilde{S}(u) = \alpha_n(u) S^*(u_N)$ so that (3.8) becomes

$$A_N \langle S_1, \ldots, S_{N-1} \rangle = \alpha_n(u) A_N S^*_N(u_N) R^*_N \cdots R^*_1. \tag{3.9}$$
However, $S(u) \mapsto S^*(u)$ defines a homomorphism $Y(\mathfrak{g}_N) \to Y(\mathfrak{g}_N)$. Therefore, writing $A_N = \text{sgn}\, \sigma \cdot A_N P_\sigma$, where $\sigma = (1N)(2N-1) \cdots$, and applying Lemma 3.3 we can simplify the right hand side of (3.9) as

$$\alpha_n(u) A_N S_N^*(u_N) R_{N-1,N}^0 \cdots R_{1N}^0 = \alpha_n(u) \frac{2u_N^2 + 1}{2u_N} A_N S_N^*(u_N).$$

Hence, we come to the identity

$$A_N (S_1, \ldots, S_{N-1}) = \alpha_{n-1}(u) A_N S_N^*((-u_N^2)).$$

Applying both sides to the basis vector $e_{a_1} \otimes \cdots \otimes e_{a_i} \otimes \cdots \otimes e_{a_N} \otimes e_{a_j}$ we get

$$\alpha_{n-1}(u) s_{a_j}(u - N/2 + 1) = (-1)^{i+j} s_{a_j}(u - N/2 + 1) = (-1)^{i+j} s_{a_j}(u).$$

The argument is completed by using the definition of $S^*(u)$.

Suppose now that $m = n - 1$. As before, we identify the subalgebra of $Y(\mathfrak{g}_N)$ generated by the elements $s_{ab}^{(r)}$ for $a, b \in \{-n, n\}$ with the twisted Yangian $Y(\mathfrak{g}_2)$. The restriction of the homomorphism (3.4) to the subalgebra $Y(\mathfrak{g}_2)$ defines the homomorphism

$$\phi : Y(\mathfrak{g}_2) \to Y(\mathfrak{g}_N).$$

The defining relations of the twisted Yangian imply that the map

$$s_{ab}(u) \mapsto \text{sgn}\, a \cdot \text{sgn}\, b \cdot s_{ab}(u), \quad a, b \in \{-n, n\}$$

defines an automorphism $\psi : Y(\mathfrak{g}_2) \to Y(\mathfrak{g}_2)$.

**Corollary 3.5.** The homomorphism $\phi$ coincides with the homomorphism (3.5) in the symplectic case, while in the orthogonal case the homomorphism (3.5) coincides with the composition $\phi \circ \psi$.

**Proof.** This is immediate from Proposition 3.4 and the skew-symmetry of the Sklyanin minors.

The symmetry relation (3.1) allows one to obtain the following expansion of the auxiliary minors (see [9, Proposition 4.4]): if $-b_1 \in \{a_1, \ldots, a_{k-1}, c\}$ and $c \notin \{-b_2, \ldots, -b_{k-1}\}$ then

$$s_{a_1 \cdots a_{k-1}, c} b_1 \cdots b_{k-1} (u) = \frac{2u + 1}{2u} \sum_{i=1}^{k-1} (-1)^{i-1} s_{a_i, b_1} (u) s_{a_1 \cdots \hat{a}_i \cdots a_{k-1}} b_2 \cdots b_{k-1} (u - 1).$$

Using this relation together with (2.12) and (2.13) one can derive explicit formulas for the Sklyanin determinant and some Sklyanin minors. The formulas use a special map

$$\omega_N : \mathfrak{S}_N \to \mathfrak{S}_N, \quad p \mapsto p'$$

(3.11)
from the symmetric group $\mathfrak{S}_N$ into itself which is defined by the following inductive procedure. Given a set of positive integers $c_1 < \cdots < c_N$ we regard $\mathfrak{S}_N$ as the group of their permutations. If $N = 2$ we define $\omega_2$ as the map $\mathfrak{S}_2 \to \mathfrak{S}_2$ whose image is the identity permutation. For $N > 2$ define a map from the set of ordered pairs $(c_k, c_l)$ with $k \neq l$ into itself by the rule

$$
\begin{align*}
(c_k, c_l) &\mapsto (c_l, c_k), & k, l < N, \\
(c_k, c_N) &\mapsto (c_{N-1}, c_k), & k < N - 1, \\
(c_N, c_k) &\mapsto (c_k, c_{N-1}), & k < N - 1, \\
(c_{N-1}, c_N) &\mapsto (c_{N-1}, c_{N-2}), \\
(c_N, c_{N-1}) &\mapsto (c_{N-1}, c_{N-2}).
\end{align*}
$$

(3.12)

Let $p = (p_1, \ldots, p_N)$ be a permutation of the indices $c_1, \ldots, c_N$. Its image under the map $\omega_N$ is the permutation $p' = (p_1', \ldots, p_{N-1}', c_N)$, where the pair $(p_1', p_{N-1}')$ is the image of the ordered pair $(p_1, p_{N-1})$ under the map (3.12). Then the pair $(p_j', p_{j-2}')$ is found as the image of $(p_j, p_{j-2})$ under the map (3.12) which is defined on the set of ordered pairs of elements obtained from $(c_1, \ldots, c_N)$ by deleting $p_1$ and $p_N$. The procedure is completed in the same manner by determining consequently the pairs $(p_i', p_{N-i})$.

Now suppose that $M$ is a positive integer and $M = 2m$ or $M = 2m + 1$. For the proof of the following formula for the Sklyanin minor in the twisted Yangian $Y(\mathfrak{g}_N)$ see [9].

Proposition 3.6. Suppose that $a_1, \ldots, a_M, b_M$ are arbitrary indices from the set $\{-n, \ldots, n\}$. We have

$$
\begin{align*}
&\text{s}_{a_1 \cdots a_M, b_M}^{-a_1 \cdots a_M, b_M}(u) \\
&= \alpha_m(u) \sum_{p \in \mathfrak{S}_M} \text{sgn} pp' \cdot s_{\alpha_p(1), \alpha_p'(1)}^{t} (-u) \cdots s_{\alpha_p(m), \alpha_p'(m)}^{t} (-u + m - 1) \\
&\quad \times \text{s}_{-a_p(m+1), a_p'(m+1)} u - m) \cdots \text{s}_{-a_p(M), a_p'(M)} u - M + 1),
\end{align*}
$$

where the $s_{ij}^t(u)$ denote the entries of the matrix $S^t(u)$. \hfill \Box

Remark 3.7. Although this determinant-like formula does not apply to arbitrary Sklyanin minors $\text{s}_{b_1 \cdots b_k}^{-a_1 \cdots a_k}(u)$, it provides explicit formulas for the Sklyanin determinant $\text{s}_{b_1 \cdots b_k}^{-a_1 \cdots a_k}(u)$ and the matrix elements $\hat{s}_{ij}(u)$ of the Sklyanin comatrix; see Proposition 3.8.

For the use in Section 5 we shall prove the following simple property of the map (3.11).

Lemma 3.8. The map $\mathfrak{S}_N \to \mathfrak{S}_N$ defined by $p \mapsto p(p')^{-1}$ is bijective.

Proof. Suppose that $p$ and $q$ are two elements of $\mathfrak{S}_N$ such that $p(p')^{-1} = q(q')^{-1}$. It suffices to show that $p = q$. By definition of the map $\omega_N$ we have $p_N' = q_N' = N$.
which implies that \( p_N = q_N \). Then, due to the formulas (3.12), we have \( p_1' = q_1' \). Hence, \( p_1 = q_1 \). Now, since the pairs \((p_1, p_N)\) and \((q_1, q_N)\) coincide, so do their images under the map (3.12). In particular, \( p_{N-1}' = q_{N-1}' \). This implies that \( p_{N-1} = q_{N-1} \) and the proof is completed by repeating this argument for the pairs \((p_{i+1}, p_{N-i})\) and \((q_{i+1}, q_{N-i})\) with \( i = 1, 2, \ldots \).

\[ \square \]

4 Skew representations

As before, we suppose that \( N = 2n \) or \( N = 2n + 1 \) so that

\[ \mathfrak{g}_N = \mathfrak{o}_{2n+1}, \quad \mathfrak{sp}_{2n}, \quad \text{or} \quad \mathfrak{o}_{2n}. \quad (4.1) \]

The finite-dimensional irreducible representations of \( \mathfrak{g}_N \) are in a one-to-one correspondence with \( n \)-tuples \( \lambda = (\lambda_1, \ldots, \lambda_n) \) where the numbers \( \lambda_i \) satisfy the conditions

\[ \lambda_i - \lambda_{i+1} \in \mathbb{Z}_+ \quad \text{for} \quad i = 1, \ldots, n-1, \]

and

\[ -2 \lambda_1 \in \mathbb{Z}_+ \quad \text{for} \quad \mathfrak{g}_N = \mathfrak{o}_{2n+1}, \]
\[ -\lambda_1 \in \mathbb{Z}_+ \quad \text{for} \quad \mathfrak{g}_N = \mathfrak{sp}_{2n}, \]
\[ -\lambda_1 - \lambda_2 \in \mathbb{Z}_+ \quad \text{for} \quad \mathfrak{g}_N = \mathfrak{o}_{2n}. \]

Such an \( n \)-tuple \( \lambda \) is called the highest weight\(^1\) of the corresponding representation which we shall denote by \( V(\lambda) \). It contains a unique, up to a constant factor, nonzero vector \( \xi \) (the highest vector) such that

\[ F_{ii} \xi = \lambda_i \xi \quad \text{for} \quad i = 1, \ldots, n, \]
\[ F_{ij} \xi = 0 \quad \text{for} \quad -n \leq i < j \leq n. \]

Let \( M \) be a nonnegative integer such that \( N - M \) is even and positive. So, \( M = 2m \) or \( M = 2m + 1 \) for some \( m < n \). We shall identify the Lie algebra \( \mathfrak{g}_M \) with the subalgebra of \( \mathfrak{g}_N \) spanned by the elements \( F_{ij} \) with the indices satisfying \(-m \leq i, j \leq m\). Denote by \( V(\lambda)^+ \) the subspace of \( \mathfrak{g}_M \)-highest vectors in \( V(\lambda) \):

\[ V(\lambda)^+ = \{ \eta \in V(\lambda) \mid F_{ij} \eta = 0, \quad -m \leq i < j \leq m \}. \]

Given a \( \mathfrak{g}_M \)-weight \( \mu = (\mu_1, \ldots, \mu_m) \) we denote by \( V(\lambda)^{\mu} \) the corresponding weight subspace in \( V(\lambda)^+ \):

\[ V(\lambda)^{\mu} = \{ \eta \in V(\lambda)^+ \mid F_{ii} \eta = \mu_i \eta, \quad i = 1, \ldots, m \}. \]

We have a natural vector space isomorphism \( V(\lambda)^{\mu} \cong \text{Hom}_{\mathfrak{g}_M}(V(\mu), V(\lambda)) \).

\(^{1}\)In a more common notation, the highest weight is the \( n \)-tuple \((-\lambda_n, \ldots, -\lambda_1)\). In particular, in the symplectic case this \( n \)-tuple is a partition.
For any $i, j \in \{-n, \ldots, n\}$ introduce the series in $u^{-1}$ with coefficients in the universal enveloping algebra $U(\mathfrak{g}_N)$ by

$$f_{ij}(u) = \delta_{ij} + F_{ij}(u)\left(u \pm \frac{1}{2}\right)^{-1}.\$$

The mapping

$$\pi : s_{ij}(u) \mapsto f_{ij}(u)$$

defines a surjective homomorphism $Y(\mathfrak{g}_N) \to U(\mathfrak{g}_N)$ called the evaluation homomorphism; see [19] and [14, Proposition 3.11]. Let $F(u)$ denote the $N \times N$ matrix whose $ij$-th entry is the series $f_{ij}(u)$. We may introduce the Sklyanin minors $f_{a_1 \cdots a_k}(u)$ of this matrix as the images of the corresponding minors of the matrix $S(u)$ with respect to the evaluation homomorphism,

$$\pi : s_{a_1 \cdots a_k}(u) \mapsto f_{a_1 \cdots a_k}(u).$$

By Theorem 3.1, we have a homomorphism $Y(\mathfrak{g}_{N-M}) \to U(\mathfrak{g}_N)$ given by

$$\rho : s_{ab}(u) \mapsto \alpha_{-m}(u) f_{-m \cdots m, a}^{-1}(u + M/2).$$

(4.3)

Due to Corollary 2.2, the image of this homomorphism is contained in the centralizer $U(\mathfrak{g}_N)^{\mathfrak{g}_M}$ of the subalgebra $\mathfrak{g}_M$ in the universal enveloping algebra $U(\mathfrak{g}_N)$. On the other hand, the vector space $V(\lambda)_\mu$ is obviously a representation of $U(\mathfrak{g}_N)^{\mathfrak{g}_M}$. Thus, $V(\lambda)_\mu$ becomes equipped with the $Y(\mathfrak{g}_{N-M})$-module structure defined via the homomorphism $\rho$. We call this module the skew representation of $Y(\mathfrak{g}_{N-M})$.

In the particular case $M = 0$ (with even $N$) the skew representation is just the evaluation module $V(\lambda)$ over $Y(\mathfrak{g}_N)$ defined via the evaluation homomorphism (4.2).

The universal enveloping algebra $U(\mathfrak{g}_{N-M})$ can be identified with a subalgebra of the twisted Yangian $Y(\mathfrak{g}_{N-M})$ via the embedding $F_{ab} \mapsto s_{ab}^{(1)}$, see [14] Proposition 3.12. The elements $F_{ab}$ are stable under the composition of this embedding with the homomorphism $\rho$. Indeed, if $a \neq b$ then this is verified directly from the definition of the Sklyanin minors with the use of (2.22). If $a = b$ then we may assume without loss of generality that $m = n - 1$ and $a = \pm n$. So, the claim follows from Corollary 3.5 and (3.3). In other words, the restriction of the $Y(\mathfrak{g}_{N-M})$-module $V(\lambda)_\mu$ to the subalgebra $U(\mathfrak{g}_{N-M})$ coincides with its natural action defined by the $U(\mathfrak{g}_N)$-action on $V(\lambda)$.

We shall now concentrate on the symplectic case $\mathfrak{g}_N = \mathfrak{sp}_N$ where $N = 2n$. Our next goal is to prove that the skew representations of $Y(\mathfrak{sp}_{N-M})$ are irreducible. First we show the following.

**Proposition 4.1.** The centralizer $U(\mathfrak{sp}_N)^{\mathfrak{sp}_M}$ is generated by the image of the homomorphism $\rho$ and the center of $U(\mathfrak{sp}_N)$.
Proof. For a different homomorphism \( \rho' : \mathcal{Y}(\mathfrak{sp}_{N-M}) \to U(\mathfrak{sp}_N)^{\mathfrak{sp}_M} \) given by

\[
s_{ab}(u) \mapsto \alpha_n(u) \hat{f}_{ab}(-u + n - 1), \quad a, b \in \mathcal{A},
\]

where \( \hat{f}_{ab}(u) \) is the image of \( \hat{s}_{ab}(u) \) under the evaluation homomorphism [12], this statement was proved in [15, Section 4]. Denote by \( \mathcal{U}' \) the subalgebra of \( U(\mathfrak{sp}_N)^{\mathfrak{sp}_M} \) generated by the center of \( U(\mathfrak{sp}_N) \) and the coefficients of the series \( f_{-m_1,...,m_n}^{a,b}(u) \) with \( a, b \in \mathcal{A} \). It is sufficient to prove that all the coefficients of the series \( \hat{f}_{ab}(u) \) belong to \( \mathcal{U}' \). However, the center of \( U(\mathfrak{sp}_N) \) is generated by the coefficients of the Sklyanin determinant \( \text{sdet} F(u) \), i.e., the image of \( \text{sdet} S(u) \) under the evaluation homomorphism [12]; see [9, Theorem 5.2]. Then by Theorem [12] the coefficients of the series \( \text{sdet} F_{BB}(u) \) belong to \( \mathcal{U}' \). Due to Proposition [27] the coefficients of the series \( f_{ab}(u) \) also belong to \( \mathcal{U}' \). \( \square \)

Corollary 4.2. The skew representation \( V(\lambda)^{\mu}_+ \) of the twisted Yangian \( \mathcal{Y}(\mathfrak{sp}_{N-M}) \) is irreducible.

Proof. Since the representation \( V(\lambda)^{\mu}_+ \) of \( U(\mathfrak{sp}_N)^{\mathfrak{sp}_M} \) is irreducible [2, Section 9.1], the statement follows from Proposition [12] as the central elements of \( U(\mathfrak{sp}_N) \) act on \( V(\lambda)^{\mu}_+ \) by scalar operators. \( \square \)

Remark 4.3. In general, the corresponding statement for the orthogonal twisted Yangian \( \mathcal{Y}(\mathfrak{o}_{N-M}) \) is false; see [13] for the particular case \( N - M = 2 \). If \( N \) is even, then the \( \mathcal{Y}(\mathfrak{o}_2) \)-module \( V(\lambda)^{\mu}_+ \) is still irreducible. If \( N \) is odd, then for general parameters \( \lambda \) and \( \mu \) the \( \mathcal{Y}(\mathfrak{o}_2) \)-module \( V(\lambda)^{\mu}_+ \) is isomorphic to the direct sum of two irreducibles. It looks plausible that, in general, the \( \mathcal{Y}(\mathfrak{o}_{N-M}) \)-module \( V(\lambda)^{\mu}_+ \) is completely reducible. It would be interesting to obtain its irreducible decomposition.

Now recall the classification results for representations of the twisted Yangian \( \mathcal{Y}(\mathfrak{sp}_N) \); see [10]. If \( V \) is a finite-dimensional irreducible representation of \( \mathcal{Y}(\mathfrak{sp}_N) \) then \( V \) contains a unique, up to a scalar factor, vector \( \xi \neq 0 \) such that

\[
s_{ii}(u) \xi = \mu_i(u) \xi \quad \text{for} \quad i = 1, \ldots, n,
\]

\[
s_{ij}(u) \xi = 0 \quad \text{for} \quad -n \leq i < j \leq n,
\]

where each \( \mu_i(u) \) is a formal series in \( u^{-1} \) with coefficients in \( \mathbb{C} \). Moreover, there exist monic polynomials \( P_i(u), \ldots, P_n(u) \) in \( u \) with \( P_1(u) = P_1(-u + 1) \) such that

\[
\frac{\mu_{i-1}(u)}{\mu_i(u)} = \frac{P_i(u + 1)}{P_i(u)}, \quad i = 2, \ldots, n
\]

and

\[
\frac{\mu_1(-u)}{\mu_1(u)} = \frac{P_1(u + 1)}{P_1(u)}.
\]

The \( n \)-tuple \( \mu(u) = (\mu_1(u), \ldots, \mu_n(u)) \) is called the highest weight and the \( P_i(u) \) are called the Drinfeld polynomials of the representation \( V \). Furthermore, given an
-tuple \((P_1(u), \ldots, P_n(u))\) of monic polynomials with \(P_1(u) = P_1(-u + 1)\) there exists a finite-dimensional irreducible representation \(V\) of \(Y(\mathfrak{sp}_N)\) having this \(n\)-tuple as the family of its Drinfeld polynomials. The isomorphism class of such representation \(V\) is determined uniquely, up to the twisting by an automorphism of \(Y(\mathfrak{sp}_N)\) of the form
\[
s_{ij}(u) \mapsto g(u)s_{ij}(u),
\]
where \(g(u)\) is a series in \(u^{-2}\) with constant term 1.

Since the Sklyanin determinant \(\text{sdet} S(u)\) is central in \(Y(\mathfrak{sp}_N)\), it acts on \(V\) by scalar multiplication. The scalar can be calculated with the use of Proposition 3.6; see also [9]. We have
\[
\text{sdet} S(u)|_V = \alpha_n(u) \prod_{i=1}^n \mu_i(-u + i - 1) \mu_i(u - N + i). \quad (4.7)
\]

**Proposition 4.4.** With the above notation, for any \(k = 1, \ldots, n\) in the representation \(V\) we have
\[
s_{-k+1 \ldots k}(u) \xi = \mu_k(u - 2k + 2) s_{-k+1 \ldots k-1}(u) \xi.
\]

**Proof.** By (2.12) we can write
\[
s_{-k+1 \ldots k}(u) = \sum_{c=-n}^n \hat{s}_{-k+1 \ldots k-1, c}(u) s_{c,k}(u - 2k + 2).
\]

Apply both sides to the highest vector \(\xi\). We have \(s_{c,k}(u - 2k + 2) \xi = 0\) if \(c < k\). On the other hand, if \(c > k\) then \(\hat{s}_{-k+1 \ldots k-1, c}(u) = 0\) by (2.13). Finally, if \(c = k\) then (2.14) gives
\[
\hat{s}_{-k+1 \ldots k-1, k}(u) = s_{-k+1 \ldots k-1}(u)
\]
completing the proof. \(\square\)

Our aim now is to identify the representation \(V(\lambda)^+_u\) of \(Y(\mathfrak{sp}_N - M)\) by calculating its highest weight and Drinfeld polynomials. Note that for the evaluation module \(V(\lambda)\) over \(Y(\mathfrak{sp}_N)\) these can be immediately found from (4.2). In particular, the \(i\)-th component of the highest weight is given by
\[
\frac{u + \lambda_i - 1/2}{u - 1/2}, \quad i = 1, \ldots, n. \quad (4.8)
\]

In the case \(M > 0\) we employ the basis in the \(\mathfrak{sp}_N\)-module \(V(\lambda)\) constructed in [11]. This basis is parameterized by the patterns \(\Lambda\) which are arrays of non-
positive integers of the form

\[
\begin{array}{cccc}
\lambda_{n1} & \lambda_{n2} & \cdots & \lambda_{nn} \\
\lambda'_{n1} & \lambda'_{n2} & \cdots & \lambda'_{nn} \\
\lambda_{n-1,1} & \cdots & \lambda_{n-1,n-1} \\
\lambda'_{n-1,1} & \cdots & \lambda'_{n-1,n-1} \\
\cdots & \cdots & \cdots & \cdots \\
\lambda'_{11} & \cdots & \cdots & \cdots \\
\end{array}
\]

where \( \lambda = (\lambda_{n1}, \ldots, \lambda_{nn}) \) is the top row of \( \Lambda \) and the following *betweenness conditions* hold

\[
0 \geq \lambda'_{ki} \geq \lambda_{ki} \geq \lambda'_{k2} \geq \lambda_{k2} \geq \cdots \geq \lambda'_{k,k-1} \geq \lambda_{k,k-1} \geq \lambda'_{kk} \geq \lambda_{kk}
\]

for \( k = 1, \ldots, n \), and

\[
0 \geq \lambda'_{k1} \geq \lambda_{k-1,1} \geq \lambda'_{k2} \geq \lambda_{k-1,2} \geq \cdots \geq \lambda'_{k,k-1} \geq \lambda_{k-1,k-1} \geq \lambda'_{kk}
\]

for \( k = 2, \ldots, n \). The representation \( V(\lambda) \) admits a basis \( \zeta_\Lambda \) parameterized by all patterns \( \Lambda \). The formulas for the matrix elements of a family of generators of the Lie algebra \( \mathfrak{sp}_N \) in this basis can be explicitly written down; see [11]. We shall only need these formulas for the generators \( F_{kk} \). We have

\[
F_{kk} \zeta_\Lambda = \left( 2 \sum_{i=1}^{k-1} \lambda'_{ki} - k \sum_{i=1}^{k} \lambda_{ki} - \sum_{i=1}^{k-1} \lambda_{k-1,i} \right) \zeta_\Lambda, \quad k = 1, \ldots, n. \quad (4.9)
\]

Given a highest weight \( \mu = (\mu_1, \ldots, \mu_m) \) for \( \mathfrak{sp}_M \), a basis of the space \( V(\lambda)_{\mu}^+ \) is formed by those vectors \( \zeta_\Lambda \) for which the row \( (\lambda_{m1}, \ldots, \lambda_{mm}) \) of \( \Lambda \) coincides with \( \mu \) and

\[
\lambda_{ki} = \lambda'_{ki} = \mu_i, \quad 1 \leq i \leq k \leq m.
\]

Omitting the same triangle part below the \( m \)-th row of all such patterns \( \Lambda \) we get trapezium-like patterns (still denoted by \( \Lambda \)) with the top row \( \lambda \) and the bottom row \( \mu \), as illustrated:

\[
\begin{array}{cccc}
\lambda_1 & \lambda_2 & \cdots & \lambda_n \\
\lambda'_{n1} & \lambda'_{n2} & \cdots & \lambda'_{n,n} \\
\cdots & \cdots & \cdots & \cdots \\
\lambda'_{m+1,1} & \lambda'_{m+1,2} & \cdots & \lambda'_{m+1,m+1} \\
\mu_1 & \mu_2 & \cdots & \mu_m \\
\end{array}
\]

Due to the betweenness conditions, the space \( V(\lambda)_{\mu}^+ \) is nonzero if and only if

\[
\mu_i \geq \lambda_{i+n-m}, \quad i = 1, \ldots, m,
\]
and
\[ \lambda_i \geq \mu_{i+n-m}, \quad i = 1, \ldots, n, \]
assuming \( \mu_i = -\infty \) for \( i > m \). We also set \( \mu_i = 0 \) for \( i \leq 0 \). In what follows we suppose that \( V(\lambda)^+ \) is nonzero.

Denote by \( h \) the diagonal Cartan subalgebra of \( \mathfrak{sp}_{N-M} \) spanned by the basis vectors \( F_{kk} \) with \( k = m+1, \ldots, n \). Let the \( \varepsilon_k \in h^* \) with \( k = m+1, \ldots, n \) be the dual basis vectors of \( h^* \). Consider the root system for \( \mathfrak{sp}_{N-M} \) with respect to \( h \) where the basis vectors \( F_{ij} \) with \( i < j \) are positive root vectors so that the positive roots are \( -2\varepsilon_k \) with \( k = m+1, \ldots, n \) and \( \pm \varepsilon_i - \varepsilon_j \) with \( m+1 \leq i < j \leq n \). By (4.9), the weight \( w(\Lambda) = (w_{m+1}, \ldots, w_n) \) of a trapezium pattern \( \Lambda \) with respect to \( h \) is given by

\[ w_k = 2 \sum_{i=1}^{k} \lambda'_{ki} - \sum_{i=1}^{k} \lambda_{ki} - \sum_{i=1}^{k-1} \lambda_{k-1,i}, \quad k = m+1, \ldots, n. \]

We shall need the standard partial ordering on the set of weights of an \( \mathfrak{sp}_{N-M} \)-module \( V \). We shall write \( w \preccurlyeq w' \) for two weights \( w \) and \( w' \) of \( V \) if \( w' - w \) is a linear combination of positive roots with nonnegative integral coefficients.

Since the vectors \( \zeta_\Lambda \) corresponding to the trapezium patterns \( \Lambda \) form a basis of the \( \mathfrak{sp}_{N-M} \)-module \( V(\lambda)^+_\mu \), the set of weights of this module is comprised by the weights \( w(\Lambda) \) for all possible patterns \( \Lambda \).

Given three integers \( i, j, k \) we shall denote by \( \text{mid}\{i, j, k\} \) that of the three which is between the two others. If one of the indices, say, \( k \) is the symbol \(-\infty\) then \( \text{mid}\{i, j, k\} \) is understood as \( \text{min}\{i, j\} \). Consider the trapezium array \( \Lambda_0 \) whose entries are determined by

\[ \lambda_{ki} = \text{mid}\{\lambda_i, \mu_{i+k-m}, \mu_{i+m-k}\} \quad (4.10) \]

and

\[ \lambda'_{ki} = \text{mid}\{\lambda_i, \mu_{i+k-m-1}, \mu_{i+m-k}\} \]

for all possible values of \( i \) and \( k \). One easily verifies that \( \Lambda_0 \) is a pattern.

**Proposition 4.5.** The \( \mathfrak{sp}_{N-M} \)-module \( V(\lambda)^+_\mu \) has a unique maximal weight. This weight coincides with \( w(\Lambda_0) \).

**Proof.** Suppose that \( w(\Lambda) \) is a maximal weight of \( V(\lambda)^+_\mu \) for some pattern \( \Lambda \). Then the entries of \( \Lambda \) should satisfy

\[ \lambda'_{ki} = \max\{\lambda_{ki}, \lambda_{k-1,i}\} \quad (4.11) \]

for all \( k = m+1, \ldots, n-1 \) and \( i = 1, \ldots, k \), where we assume \( \lambda_{ki} = -\infty \) for \( i > k \). Indeed, if the equality is not attained for some \( k \) and \( i \) then by the betweenness conditions we have \( \lambda'_{ki} > \max\{\lambda_{ki}, \lambda_{k-1,i}\} \). Therefore, decreasing the entry \( \lambda'_{ki} \) by
1 we get a pattern of greater weight than $w(\Lambda)$ which contradicts the maximality of $w(\Lambda)$. Thus, the weight $w(\Lambda) = (w_m, \ldots, w_n)$ can now be written as

$$w_k = \sum_{i=1}^{k-1} |\lambda_{ki} - \lambda_{k-1,i}| + \lambda_{kk}, \quad k = m + 1, \ldots, n.$$ 

We shall argue by induction on $n - m$ to show that the $\lambda_{ki}$ must be given by (4.10). This will imply the statement since the entries of $\Lambda_0$ do satisfy (4.11) which is easily seen. In the case $n - m = 1$ there is nothing to prove. Suppose that $n - m = 2$.

Omitting the primed entries, we can depict $\Lambda$ as

$$\begin{array}{cccccc}
\lambda_1 & \lambda_2 & \cdots & \lambda_{n-2} & \lambda_{n-1} & \lambda_n \\
\rho_1 & \rho_2 & \cdots & \rho_{n-2} & \rho_{n-1} \\
\mu_1 & \mu_2 & \cdots & \mu_{n-2} \\
\end{array}$$

where we have put $\rho_i = \lambda_{n-1,i}$. The weight $w(\Lambda) = (w_{n-1}, w_n)$ is given by

$$w_{n-1} = \sum_{i=1}^{n-2} |\rho_i - \mu_i| + \rho_{n-1},$$

$$w_n = \sum_{i=1}^{n-1} |\lambda_i - \rho_i| + \lambda_n. \quad (4.12)$$

Suppose that (4.10) is violated for some $i$ so that $\rho_i \neq \text{mid}\{\lambda_i, \mu_{i+1}, \mu_{i-1}\}$. Observe that by the betweenness conditions we have

$$\rho_{i+1} \leq \text{mid}\{\lambda_i, \mu_{i+1}, \mu_{i-1}\} \leq \rho_{i-1}.$$ 

Hence, if $\rho_i < \text{mid}\{\lambda_i, \mu_{i+1}, \mu_{i-1}\}$ (respectively, $\rho_i > \text{mid}\{\lambda_i, \mu_{i+1}, \mu_{i-1}\}$) then we can increase (respectively, decrease) the value of $\rho_i$ by 1 without violating the betweenness conditions and thus to get another pattern $\Lambda'$. Due to the formulas (4.12), we have $w(\Lambda) < w(\Lambda')$ which contradicts the maximality of $w(\Lambda)$. This proves the statement in the case under consideration.

Suppose now that $n - m > 2$. Let us set $\rho_i = \lambda_{n-1,i}$ as above, and consider the set of patterns having $\rho = (\rho_1, \ldots, \rho_{n-1})$ as the top row and $\mu$ as the bottom row. Then, by the maximality of $w(\Lambda)$, the trapezium subpattern of $\Lambda$ with the top row $\rho$ and bottom row $\mu$ will clearly be of a maximal weight amongst all patterns of this set. By the induction hypothesis, we must have

$$\lambda_{ki} = \text{mid}\{\rho_i, \mu_{i+k-m}, \mu_{i+m-k}\} \quad (4.13)$$

for all $k = m + 1, \ldots, n - 2$ and $i = 1, \ldots, k$. Similarly, the subpattern of $\Lambda$ having the top row $\lambda$ and the bottom row $\sigma = (\sigma_1, \ldots, \sigma_{n-2})$ is of a maximal
weight amongst all patterns of this form, where we have put \( \sigma_i = \lambda_{n-2,i} \). By the statement for the case \( n - m = 2 \), we must have

\[
\rho_i = \text{mid}\{\lambda_i, \sigma_{i+1}, \sigma_{i-1}\}, \quad i = 1, \ldots, n - 1.
\]

Combining this with the relations \( \sigma_i = \text{mid}\{\rho_i, \mu_{i+n-m-2}, \mu_{i+m-n+2}\} \) implied by (4.13), we get the desired relation for the row \( \rho \) of \( \Lambda \).

\[
\rho_i = \text{mid}\{\lambda_i, \mu_{i+n-m-1}, \mu_{i+m-n+1}\}, \quad i = 1, \ldots, n - 1.
\]

Indeed, this is easily verified by looking at all possible combinations of the three values of each of \( \sigma_{i-1} \) and \( \sigma_{i+1} \). Finally, substituting these values of \( \rho_i \) into (4.13) we conclude that (4.10) holds for all possible \( k \) and \( i \). Thus, \( \Lambda \) coincides with \( \Lambda_0 \).

**Corollary 4.6.** The vector \( \zeta_{\Lambda_0} \) is the highest vector of the \( Y(\mathfrak{sp}_{N-M}) \)-module \( V(\lambda)^+_\mu \).

**Proof.** It suffices to demonstrate that \( \zeta_{\Lambda_0} \) is annihilated by all generators \( s_{ab}(u) \) of \( Y(\mathfrak{sp}_{N-M}) \) with \( a < b \), since by [10] Remark 4.4 the vector \( \zeta_{\Lambda_0} \) will then have to be an eigenvector for all \( s_{aa}(u) \) with \( a = m + 1, \ldots, n \).

Recall that \( s_{ab}(u) \) acts on \( V(\lambda)^+_\mu \) as a Sklyanin minor which is a series in \( u^{-1} \) with coefficients in the universal enveloping algebra \( U(\mathfrak{sp}_N) \); see (4.3). Using Proposition 2.1 it is easy to derive that the weight of all these coefficients coincides with the weight of the element \( F_{ab} \) with respect to the adjoint action of the Cartan subalgebra \( \mathfrak{h} \) of \( \mathfrak{sp}_{N-M} \). Therefore, if \( a < b \) then the vector \( s_{ab}(u) \zeta_{\Lambda_0} \) has the weight \( w(\Lambda_0) + a \) for a positive root \( a \). Now the claim follows from Proposition 4.5.

Corollary 4.6 implies that the highest weight \( \mu(u) = (\mu_{m+1}(u), \ldots, \mu_n(u)) \) of the \( Y(\mathfrak{sp}_{N-M}) \)-module \( V(\lambda)^+_\mu \) is determined by the relations

\[
s_{aa}(u) \zeta_{\Lambda_0} = \mu_a(u) \zeta_{\Lambda_0}, \quad a = m + 1, \ldots, n.
\]

In order to calculate \( \mu(u) \) we shall use the results of [11], where the particular case \( m = n - 1 \) was considered. In [11] the vector space \( V(\lambda)^+_\mu \) was endowed with the \( Y(\mathfrak{sp}_2) \)-module structure defined by the composition of an automorphism of the type (3.2) and the homomorphism (4.4). Therefore, using Corollary 3.5 we can reformulate the result for the \( Y(\mathfrak{sp}_2) \)-module structure on \( V(\lambda)^+_\mu \) defined by the homomorphism (4.3) to obtain the following.

**Proposition 4.7.** For \( m = n - 1 \) in the \( Y(\mathfrak{sp}_2) \)-module \( V(\lambda)^+_\mu \) we have

\[
\alpha_{-n+1}(u) f_{-n+1}^{u+1} \cdots f_n^{u+n-1} \zeta_{\Lambda_0} = \prod_{i=2}^n \frac{u - \text{mid}\{\lambda_{i-1}, \mu_{i-1}\} + i - 1/2}{u + i - 1/2} \prod_{i=1}^n \frac{u + \text{mid}\{\lambda_i, \mu_i\} - i + 1/2}{u - i + 1/2} \zeta_{\Lambda_0}.
\]

28
In the case of arbitrary \( m < n \) introduce the following notation:

\[
\nu(u) = \prod_{i=1}^{m} \frac{(u + \mu_i - i + 1/2)(u - \mu_i + i + 1/2)}{(u - i + 1/2)(u + i + 1/2)}. \tag{4.14}
\]

**Theorem 4.8.** The highest weight \( \mu(u) = (\mu_{m+1}(u), \ldots, \mu_n(u)) \) of the \( Y(sp_{N-M}) \)-module \( V(\lambda)_{\mu}^{+} \) is given by the formulas

\[
\mu_k(u) = \nu(u) \cdot \prod_{i=1}^{k-1} \frac{u - \text{max}\{\lambda_i, \mu_{i+k-m}\} + k - m + i - 1/2}{u - \mu_{i+k-m-1} + k - m + i - 1/2}
\times \prod_{i=1}^{k-1} \frac{u + \text{min}\{\lambda_i, \mu_{i+m-k}\} + k - m - i - 1/2}{u + \mu_{i+m-k+1} + k - m - i - 1/2}
\times \frac{u + \text{min}\{\lambda_k, \mu_m\} - m - 1/2}{u - m - 1/2},
\]

where \( k = m + 1, \ldots, n \).

**Proof.** Let us denote by \( \varphi_{ab}(u) \) the image of the series \( s_{ab}(u) \) under the homomorphism \( \rho \) defined in \( \text{[13]} \), that is,

\[
\varphi_{ab}(u) = \alpha_{-m}(u) f_{-m \cdots m, a} (u + M/2). \tag{4.15}
\]

Combine these series into the \((N-M) \times (N-M)\) matrix \( \Phi(u) \). We shall use the usual notation for the Sklyanin comatrix and the Sklyanin minors of \( \Phi(u) \).

Applying Proposition \( \text{[24]} \), we obtain the following expression for the \( mn \)-th entry of the Sklyanin comatrix \( \Phi(u) \),

\[
\hat{\varphi}_{mn}(u) = \alpha_{-m}(u) \hat{f}_{mn}(u + M/2) \cdot f_G(u - 1) \cdots f_G(u - N + M + 2), \tag{4.16}
\]

where we have put \( f_G(u) = \alpha_{-m}(u) \text{sdet} F_{BG}(u + M/2) \). On the other hand, by Proposition \( \text{[34]} \) we have

\[
\hat{\varphi}_{mn}(u) = \alpha_{N-M-1}(u) \varphi_{-n+1 \cdots -m-1, m+1 \cdots n} (-u + N - M - 2)
\]

and

\[
\hat{f}_{mn}(u) = \alpha_{N-1}(u) f_{-n+1 \cdots n} (-u + N - 2).
\]

Therefore, by \( \text{[31]} \),

\[
\alpha_{N-M-1}(u) \varphi_{-n+1 \cdots -m-1, m+1 \cdots n} (-u + N - M - 2) =
\alpha_{N-1}(u + M/2) f_{-n+1 \cdots n} (-u + N - M/2 - 2)
\times \alpha_{-m}(u) f_G(u - 1) \cdots f_G(u - N + M + 2). \tag{4.17}
\]
Similarly, applying Theorem 3.1 we derive the identity

\[
\alpha_{N-M}(u) \varphi_{-n \ldots -m-1, m+1 \ldots n} (-u + N - M - 1) = \\
\alpha_N(u + M/2) f_{-n \ldots n} (-u + N - M/2 - 1) \\
\times \alpha_m(u) f_B(u - 1) \cdots f_B(u - N + M + 1).
\]

Replacing here \(n\) by \(n - 1\) and \(u\) by \(u - 1\) we get

\[
\alpha_{N-M-2}(u - 1) \varphi_{-n+1 \ldots -m-1, m+1 \ldots n} (-u + N - M - 2) = \\
\alpha_{N-2}(u + M/2 - 1) f_{-n+1 \ldots n-1} (-u + N - M/2 - 2) \\
\times \alpha_m(u - 1) f_B(u - 2) \cdots f_B(u - N + M + 2). \quad (4.18)
\]

Due to Proposition 4.4 in \(V(\lambda)^+\) we have

\[
\varphi_{-n+1 \ldots -m-1, m+1 \ldots n}(v) \zeta_{\lambda_0} = \\
\mu_n(v - N + M + 2) \varphi_{-n+1 \ldots -m-1, m+1 \ldots n-1}(v) \zeta_{\lambda_0}.
\]

Hence, comparing (4.17) and (4.18) we come to the relation

\[
f_B(u - 1) f_{-n+1 \ldots n} (-u + 2n - m - 2) \zeta_{\lambda_0} = \\
\mu_n(-u) f_{-n+1 \ldots n-1} (-u + 2n - m - 2) \zeta_{\lambda_0}.
\]

Therefore, for each \(k = m + 1, \ldots, n\) the corresponding component of the highest weight of the \(Y(sp_{N-M})\)-module \(V(\lambda)^+_\mu\) can be found from the relation

\[
f_B(-u - 1) f_{-k+1 \ldots k} (u + 2k - m - 2) \zeta_{\lambda_0} = \\
\mu_k(u) f_{-k+1 \ldots k-1} (u + 2k - m - 2) \zeta_{\lambda_0}. \quad (4.19)
\]

Observe that each of the Sklyanin minors \(f_{-k+1 \ldots k}(v)\) and \(f_{-k+1 \ldots k-1}(v)\) commutes with all elements of the subalgebra \(sp_{2k-2}\) by Corollary 4.2. Therefore, since the basis \(\{\zeta_{\lambda}\}\) of \(V(\lambda)\) is consistent with the embeddings \(sp_{2k-2} \subset sp_{2k}\), the vector \(\zeta_{\lambda_0}\) is an eigenvector for each of these minors. The corresponding eigenvalue for the first minor can be calculated from Proposition 4.7 so that

\[
\alpha_{-k+1}(u) f_{-k+1 \ldots k} (u + k - 1) \zeta_{\lambda_0} = \\
\prod_{i=2}^{k} \frac{u - \min\{\lambda_{k,i-1}, \lambda_{k-1,i-1}\} + i - 1/2}{u + i - 1/2} \\
\times \prod_{i=1}^{k} \frac{u + \max\{\lambda_{k,i}, \lambda_{k-1,i}\} - i + 1/2}{u - i + 1/2} \zeta_{\lambda_0}, \quad (4.20)
\]

30
where the $\lambda_{ki}$ are the entries of $\Lambda_0$. The second minor coincides with the image of the Sklyanin determinant for $Y(\mathfrak{sp}_{2k-2})$ under the evaluation homomorphism $\mathbf{1}_w^2$. Hence the corresponding eigenvalue can be found from (4.7) and (4.8) which gives

$$
\alpha_{-k+1}(u) f_{-k+1} \cdots f_{-1} (u + k - 1) \zeta_{\Lambda_0} = \prod_{i=2}^{k} \frac{u - \lambda_{k-1,i-1} + i - 1/2}{u + i - 1/2} \cdot \prod_{i=1}^{k-1} \frac{u + \lambda_{k-1,i} - i + 1/2}{u - i + 1/2} \zeta_{\Lambda_0};
$$

see also [9]. Note that since $f_{\mathfrak{g}}(u) = \alpha_{-m}(u) f_{-m} \cdots f_{-1} (u + m)$, the last formula with $k = m + 1$ also applies for the calculation of $f_{\mathfrak{g}}(u) \zeta_{\Lambda_0}$. Hence,

$$
f_{\mathfrak{g}}(-u - 1) \zeta_{\Lambda_0} = \nu(u) \zeta_{\Lambda_0} \quad (4.21)
$$

with $\nu(u)$ defined in (4.14). Furthermore, the formulas (4.10) for the entries of $\Lambda_0$ imply that

$$
\max\{\lambda_{ki}, \lambda_{k-1,i}\} = \text{mid}\{\lambda_i, \mu_{i+k-m-1}, \mu_{i+m-k}\} \quad (4.22)
$$

and

$$
\min\{\lambda_{ki}, \lambda_{k-1,i}\} = \text{mid}\{\lambda_i, \mu_{i+k-m}, \mu_{i+m-k+1}\}. \quad (4.23)
$$

Using (4.19) we obtain the following expression for $\mu_k(u)$:

$$
\mu_k(u) = \nu(u) \prod_{i=2}^{k} \frac{u - \text{mid}\{\lambda_i, \mu_{i+k-m-1}, \mu_{i+m-k}\} + k - m + i - 3/2}{u - \text{mid}\{\lambda_i, \mu_{i+k-m-2}, \mu_{i+m-k}\} + k - m + i - 3/2} \times \prod_{i=1}^{k-1} \frac{u + \text{mid}\{\lambda_i, \mu_{i+k-m-1}, \mu_{i+m-k+1}\} + k - m - i - 1/2}{u + \text{mid}\{\lambda_i, \mu_{i+k-m-1}, \mu_{i+m-k+1}\} + k - m - i - 1/2} \times \frac{u + \text{mid}\{\lambda_k, \mu_m\} - m - 1/2}{u - m - 1/2}. \quad (4.24)
$$

Finally, replace the index $i$ in the first product by $i + 1$ and note that if $\lambda_i \geq \mu_{i+k-m-1}$ then the corresponding factor equals 1. Similarly, if $\lambda_i \leq \mu_{i+m-k+1}$ then the corresponding factor in the second product equals 1. This brings the expression for $\mu_k(u)$ to the required form.

We can now compute the Drinfeld polynomials for the $Y(\mathfrak{sp}_{N-M})$-module $V(\lambda)^+_{\mathfrak{g}}$ by using Theorem 4.8. Given any $\mathfrak{sp}_{2n}$-highest weight $\lambda = (\lambda_1, \ldots, \lambda_n)$, set $\lambda_{-i} = -\lambda_i$ for $i = 1, \ldots, n$. We also assume that $\lambda_0 = 0$ while $\lambda_k = -\infty$ and $\lambda_{-k} = +\infty$ for $k > n$. Introduce the diagram $\Gamma(\lambda)$ as a certain infinite set of unit squares (cells) on the plane whose centers have integer coordinates. The coordinates $(i, j)$ of a cell are interpreted as the row and column number so that
i increases from top to bottom and j increases from left to the right. With these assumptions\(^2\),

$$\Gamma(\lambda) = \{(i, j) \in \mathbb{Z}^2 \mid -n \leq i \leq n + 1, \quad \lambda_i \leq j < \lambda_{i-1}\}.$$  

The diagram has a central symmetry, as illustrated below for \(\lambda = (-4, -7)\) and \(n = 2\):

![Diagram](image)

Note that in the case \(n = 0\) the definition of the diagram formally makes sense with \(\lambda\) considered to be empty. Thus, \(\Gamma(\emptyset)\) consists of two infinite rows of cells:

![Diagram](image)

By the content of a cell \(\alpha = (i, j)\) with coordinates \(i\) and \(j\) we shall mean the number \(c(\alpha) = j - i\). For any nonnegative integer \(p\) we shall denote by \(\Gamma(\lambda)^{(p)}\) the image of \(\Gamma(\lambda)\) with respect to the shift operator \((i, j) \mapsto (i - p, j)\). In other words, \(\Gamma(\lambda)^{(p)}\) is obtained from the diagram \(\Gamma(\lambda)\) by lifting each cell \(p\) units up.

We let \(P_1(u), \ldots, P_{n-m}(u)\) denote the Drinfeld polynomials corresponding to the \(\mathfrak{sp}_{N-M}\)-module \(V(\lambda)^{+}\).

**Theorem 4.9.** For each \(k = 1, \ldots, n - m\) the Drinfeld polynomial \(P_k(u)\) is given by

$$P_k(u) = \prod_\alpha (u + c(\alpha) + 1/2),$$

where \(\alpha\) runs over the cells of the intersection \(\Gamma(\mu) \cap \Gamma(\lambda)^{(k-1)}\).

**Example 4.10.** Let \(\lambda = (-2, -8, -10, -13)\) and \(\mu = (-4, -7)\) so that \(n = 4\) and \(m = 2\). (In a more standard notation, \(\lambda\) and \(\mu\) can be thought of as the partitions \((13, 10, 8, 2)\) and \((7, 4)\), respectively). The polynomial \(P_1(u)\) is calculated from the figure:

\(^2\)This definition of \(\Gamma(\lambda)\) corresponds to the one outlined in the Introduction for the partition \((\lambda_{-n}, \ldots, \lambda_{-1})\).
The horizontal and vertical shadings indicate the diagrams $\Gamma(\lambda)$ and $\Gamma(\mu)$, respectively. The cells belonging to the intersection $\Gamma(\mu) \cap \Gamma(\lambda)$ have the coordinates $(3, -10), (3, -9), (2, -7), (2, -6), (2, -5), (1, -2), (1, -1), (0, 0), (0, 1), (-1, 4), (-1, 5), (-1, 6), (-2, 8), (-2, 9)$. Hence,

$$P_1(u) = (u - 25/2)(u - 23/2)(u - 17/2)(u - 15/2)(u - 13/2)(u - 5/2)(u - 3/2)(u + 3/2)(u + 11/2)(u + 13/2)(u + 15/2)(u + 21/2)(u + 23/2).$$

Note that the property $P_1(u) = P_1(-u + 1)$ is implied by the central symmetry of the set $\Gamma(\mu) \cap \Gamma(\lambda)$.

The polynomial $P_2(u)$ is calculated from the figure:

The cells which belong to the intersection $\Gamma(\mu) \cap \Gamma(\lambda)^{(1)}$ have the coordinates $(3, -13), (3, -12), (3, -11), (1, -4), (1, -3), (-2, 7)$. Hence,

$$P_2(u) = (u - 31/2)(u - 29/2)(u - 27/2)(u - 9/2)(u - 7/2)(u + 19/2).$$

**Example 4.11.** In the case $m = 0$ the vector space $V(\lambda)^\perp_{\mu}$ can be identified with $V(\lambda)$ and the corresponding $Y(\mathfrak{sp}_{2n})$-module coincides with the evaluation
module defined by the evaluation homomorphism (1.2). Applying Theorem 4.9 to
the diagrams \( \Gamma(\lambda) \) and \( \Gamma(\emptyset) \) we obtain

\[
P_1(u) = (u + \lambda_1 - 1/2)(u + \lambda_1 + 1/2) \cdots (u - 3/2)
\times (u + 1/2)(u + 3/2) \cdots (u - \lambda_1 - 1/2)
\]

and

\[
P_k(u) = (u + \lambda_k - 1/2)(u + \lambda_k + 1/2) \cdots (u + \lambda_{k-1} - 3/2), \quad k = 2, \ldots, n.
\]

On the other hand, the highest weight of this module is given by (4.8). Due to
(4.5) and (4.6) this obviously agrees with the above calculation of the
\( P_k(u) \).

**Proof of Theorem 4.9.** We shall derive the statement from Theorem 4.8 and the
definition of the Drinfeld polynomials (4.5) and (4.6). In order to calcu late
\( P_1(u) \) observe that the component \( \mu_{m+1}(u) \) of the highest weight can also be found from
the formula

\[
\varphi_{m+1,m+1}(u) \zeta_{\Lambda_0} = \mu_{m+1}(u) \zeta_{\Lambda_0};
\]

see (4.15). Hence, applying (4.20) with \( k = m + 1 \) and using (4.22) and (4.23) we
get

\[
\mu_{m+1}(u) = \prod_{i=1}^{m+1} \frac{u - \text{mid}\{\lambda_i-1, \mu_i-1, \mu_i\} + i - 1/2}{u + i - 1/2}
\times \prod_{i=1}^{m+1} \frac{u + \text{mid}\{\lambda_i, \mu_i-1, \mu_i\} - i + 1/2}{u - i + 1/2}.
\]

Therefore, by (4.6),

\[
\frac{P_1(u+1)}{P_1(u)} = \prod_{i=1}^{m+1} \frac{u + \text{mid}\{\lambda_i-1, \mu_i-1, \mu_i\} - i + 1/2}{u + \text{mid}\{\lambda_i, \mu_i-1, \mu_i\} - i + 1/2}
\times \prod_{i=1}^{m+1} \frac{u - \text{mid}\{\lambda_i, \mu_i-1, \mu_i\} + i - 1/2}{u - \text{mid}\{\lambda_i-1, \mu_i-1, \mu_i\} + i - 1/2}.
\]

This gives \( P_1(u) = Q(u) Q(-u+1) (-1)^{\text{deg}Q}, \) where

\[
Q(u) = \prod_{i=1}^{m+1} (u + \beta_i)(u + \beta_i + 1) \cdots (u + \alpha_i - 1)
\]

with

\[
\alpha_i = \text{mid}\{\lambda_i-1, \mu_i-1, \mu_i\} - i + 1/2 \quad \text{and} \quad \beta_i = \text{mid}\{\lambda_i, \mu_i-1, \mu_i\} - i + 1/2.
\]
Thus, the factor corresponding to the index $i$ in the product in (4.24) can be interpreted as the product $\prod_{\lambda}(u + c(\alpha) + 1/2)$, where $\alpha$ runs over the cells of the intersection of the diagrams $\Gamma(\lambda) \cap \Gamma(\mu)$ whose first coordinate is $i$. Taking into account the central symmetry of $\Gamma(\lambda) \cap \Gamma(\mu)$, we derive the desired formula for $P_r(u)$.

Now using (4.5) and replacing the index $k$ by $r = k - m$ in Theorem 4.8, we derive the following expression for the Drinfeld polynomial $P_{r+1}(u)$ with $1 \leq r < n - m$:

\[
\frac{P_{r+1}(u + 1)}{P_{r+1}(u)} = \frac{u - \max\{\lambda_{i+1}, \mu_{i+r+1}\} + r + i + 1/2}{u - \max\{\lambda_i, \mu_{i+r+1}\} + r + i + 1/2} \times \frac{u - \max\{\lambda_i, \mu_{i+r}\} + r + i - 1/2}{u - \mu_{i+r-1} + r + i - 1/2} \times \frac{u + \min\{\lambda_i, \mu_{i-r-1}\} + r - i + 1/2}{u + \min\{\lambda_i, \mu_{i-r}\} + r - i + 1/2} \times \frac{u + \min\{\lambda_{i+1}, \mu_{i-r}\} + r - i - 1/2}{u + \mu_{i-r+1} + r - i + 1/2}.
\]

(4.25)

Note that the expression has the form

\[
\frac{P_{r+1}(u + 1)}{P_{r+1}(u)} = \prod_j \frac{u + \alpha_j}{u + \beta_j}
\]

for some parameters $\alpha_j$ and $\beta_j$ with $\alpha_j - \beta_j \in \mathbb{Z}_+$. This implies that $P_{r+1}(u)$ is given by

\[
P_{r+1}(u) = \prod_j (u + \beta_j)(u + \beta_j + 1) \cdots (u + \alpha_j - 1).
\]

(4.26)

It is straightforward to verify that this product coincides with $\prod_{\alpha}(u + c(\alpha) + 1/2)$, where $\alpha$ runs over the cells of the intersection $\Gamma(\mu) \cap \Gamma(\lambda)^{(r-1)}$. Indeed, changing the product index $i$ respectively by $i - r$ and by $i - r + 1$ in the third and fourth products in (4.25), we bring these products to the form

\[
\prod_{\lambda_{i+r} > \mu_i}^{m+1} \frac{u + \min\{\lambda_{i+r-1}, \mu_{i-1}\} - i + 1/2}{u + \min\{\lambda_{i+r-1}, \mu_{i-1}\} - i + 1/2} \times \prod_{\lambda_{i+r} \leq \mu_i < \lambda_{i+r-1}}^{m+1} \frac{u + \min\{\lambda_{i+r-1}, \mu_{i-1}\} - i + 1/2}{u + \mu_i - i + 1/2}.
\]

(4.27)
Therefore, the factor corresponding to the index $i$ contributes into the product $\prod_\alpha (u + c(\alpha) + 1/2)$, where $\alpha$ runs over the cells of the intersection $\Gamma(\mu) \cap \Gamma(\lambda)^{(r-1)}$ whose first coordinate is $i$. Note that writing

$$-\max\{\lambda_i, \mu_i + r + 1\} = \min\{\lambda_{-i}, \mu_{-i} - r - 1\}$$

we can similarly bring the first and second products in (4.25) to the form (4.27), where the product is taken over negative indices. This contributes the product $\prod_\alpha (u + c(\alpha) + 1/2)$ into (4.26), where $\alpha$ runs over the cells of the intersection $\Gamma(\mu) \cap \Gamma(\lambda)^{(r-1)}$ whose first coordinate is non-positive.

5 Centralizer construction

We now return to our general situation so that $g_N$ denotes either the orthogonal or symplectic Lie algebra; see (4.1). We start by recalling the construction of the Olshanski algebra $A_M$; see [19, 15]. Fix a nonnegative integer $M$ such that $N - M$ is even. So, if $N = 2n$ or $N = 2n + 1$ then $M = 2m$ or $M = 2m + 1$, respectively, for some $m \leq n$. Denote by $g'_{N-M}$ the subalgebra of $g_N$ spanned by the elements $F_{ij}$ subject to the condition $m+1 \leq |i|, |j| \leq n$. Let $A_M(N)$ denote the centralizer of $g'_{N-M}$ in the universal enveloping algebra $U(g_N)$. Let $U(g_N)^0$ denote the centralizer of $F_{nn}$ in $U(g_N)$ and let $I(N)$ be the left ideal in $U(g_N)$ generated by the elements $F_{ni}, i = -n, \ldots, n$. Then $I(N)^0 = I(N) \cap U(g_N)^0$ is a two-sided ideal in $U(g_N)^0$ which coincides with the intersection $J(N) \cap U(g_N)^0$, where $J(N)$ is the right ideal in $U(g_N)$ generated by the elements $F_{ni}, i = -n, \ldots, n$. One has a vector space decomposition

$$U(g_N)^0 = I(N)^0 \oplus U(g_{N-2}).$$

Therefore the projection of $U(g_N)^0$ onto $U(g_{N-2})$ with the kernel $I(N)^0$ is an algebra homomorphism. Its restriction to the subalgebra $A_M(N)$ defines a filtration-preserving homomorphism

$$\pi_N : A_M(N) \to A_M(N-2) \quad (5.1)$$

so that one can define the algebra $A_M$ as the projective limit with respect to this sequence of homomorphisms in the category of filtered algebras; see [15] for more details.

Taking the composition of the homomorphism $Y(g_M) \to Y(g_N)$ defined in Proposition 4.2 and the evaluation homomorphism 4.2, we obtain another homomorphism $\psi_N : Y(g_M) \to U(g_N)$ which takes $s_{ij}(u)$ to the series

$$\alpha_{m-n}(u) \cdot f_{-n \ldots -m-1, i, m+1 \ldots n}(u + n - m), \quad -m \leq i, j \leq m, \quad (5.2)$$

where we have used the notation of Section 4 for the images of the Sklyanin minors with respect to 4.2. Observe now that by Corollary 2.2 the image of $\psi_N$ is contained in the centralizer $A_M(N)$, so that $\psi_N : Y(g_M) \to A_M(N)$.

36
Proposition 5.1. The sequence of homomorphisms \((\psi_N| N = M + 2k, k = 0, 1, \ldots)\) defines a homomorphism

\[ \psi : Y(\mathfrak{g}_M) \rightarrow \Lambda_M. \]

Proof. We have to verify that the homomorphisms \(\psi_N\) are compatible with the sequence of homomorphisms \((\pi_M)\), that is, the following diagram is commutative:

\[
\begin{array}{c}
Y(\mathfrak{g}_M) \quad \quad Y(\mathfrak{g}_M) \quad \quad \cdots \quad \quad Y(\mathfrak{g}_M) \quad \quad \cdots \\
\downarrow \psi_M \quad \quad \downarrow \psi\pi_{M+2} \quad \quad \cdots \quad \quad \downarrow \psi N \quad \quad \cdots \\
\Lambda_M(M) \quad \quad \Lambda_M(M+2) \quad \quad \cdots \quad \quad \Lambda_M(N) \quad \quad \cdots
\end{array}
\]

Let us calculate the image of the series \(\psi_N(s_{ij}(u))\) under the homomorphism \(\pi_N\). Applying (2.12), we obtain

\[
f_{-n-\cdots-m-1, i, m+1\cdots n} (u + n - m) = \sum_{c} f_{-n-\cdots-m-1, i, m+1\cdots n}^{-c}(u + n - m) f_{cn}(u - n + m),
\]

where by \(f_{b_1\cdots b_{k-1},c}(u)\) we denote the image of the auxiliary minor \(\tilde{s}^{a_1\cdots a_k}_{b_1\cdots b_{k-1},c}(u)\) under the evaluation homomorphism (12). Now observe that \(f_{cn}(u-n+m)\) belongs to the left ideal \(I(N)\) unless \(c = n\). In this case \(f_{nn}(u-n+m) \equiv 1 \mod I(N)\).

Furthermore, by (5.11),

\[
f_{-n-\cdots-m-1, i, m+1\cdots n}^{a_1\cdots a_k} (v) = \frac{2v+1}{2v\pm 1} \sum_{i=1}^{2n-2m} (-1)^{-i} f_{a_i,-n}^{a_1\cdots \hat{a_i}\cdots a_{2n-2m}} f_{-n+1\cdots-m-1,j,m+1\cdots n-1}(v-1),
\]

where we have set \((a_1,\ldots,a_{2n-2m}) = (-n\cdots-m-1, i, m+1\cdots n-1)\) and \(v = u + n - m\). Now \(f_{a_i,-n}(v) = \theta_{-n,a_i} f_{n,-a_i}(-v)\) belongs to the right ideal \(J(N)\) unless \(a_i = -n\), that is, \(i = 1\). In this case \(f_{nn}(-v) \equiv 1 \mod J(N)\). Note that

\[
\alpha_{m-n}(u) = \frac{2v+1}{2v\pm 1} = \alpha_{m-n+1}(u).
\]

Hence, \(\pi_N\) takes \(\psi_N(s_{ij}(u))\) to the series

\[
\alpha_{m-n+1}(u) \cdot f_{-n+1\cdots-m-1,i,m+1\cdots n-1}(u + n - m - 1)
\]

which coincides with \(\psi_{N-2}(s_{ij}(u))\). Thus, the sequence of coefficients at each power of \(u^{-1}\) in \(\psi_N(s_{ij}(u))\) with \(N = M + 2k, k = 0, 1, \ldots\) defines an element of \(\Lambda_M\). \(\square\)
Corollary 2.2 implies that all the coefficients of the series

\[ \alpha_{m-n}(u) \cdot f^{-n}\cdots-m-1,m+1\cdots n \ (u+n-m) = 1 + \delta_{1}^{(m+1)} u_{1}^{1} + \delta_{2}^{(m+2)} u_{2}^{2} + \cdots \]  

belong to the center of the universal enveloping algebra \( U(\mathfrak{g}_{N-M}) \). Hence, for any \( i \) the coefficient \( \delta_{i}^{(m+1)} \) is an element of the centralizer \( A_{M}(N) \). The argument of the proof of Proposition 5.1 shows that the image of the series (5.3) under the homomorphism \( \pi_{N} \) is

\[ \alpha_{m-n+1}(u) \cdot f^{-n+1}\cdots-m-1,m+1\cdots n-1 \ (u+n-m-1). \]

Therefore, for each \( i \) the sequence \( c_{i} = (\delta_{i}^{(m+1)} | n \geq m+1) \) determines an element of the projective limit algebra \( A_{M} \). Denote by \( C_{M} \) the subalgebra of \( A_{M} \) generated by all \( c_{i} \) with \( i \geq 1 \). The subalgebra \( C_{M} \) is studied in detail in [15, Section 3] where it was identified with the algebra of virtual Laplace operators. Up to an obvious change of notation, the series (5.3) coincides with the Sklyanin minor \( f_{B}(u) \) introduced in the proof of Theorem 4.8. So its Harish-Chandra image can be found from (4.21) which shows that the elements \( c_{2i} \) with even indices are algebraically independent and generate the algebra \( C_{M} \); cf. [15, Section 3].

**Theorem 5.2.** The homomorphism \( \psi : Y(\mathfrak{g}_{M}) \hookrightarrow A_{M} \) is injective. Moreover, one has an isomorphism

\[ A_{M} = C_{M} \otimes Y(\mathfrak{g}_{M}), \]

where \( Y(\mathfrak{g}_{M}) \) is identified with its image under the embedding \( \psi \).

**Proof.** Our argument is similar to the proof of [15, Theorem 4.17]. Consider the canonical filtration of the universal enveloping algebra \( U(\mathfrak{g}_{N}) \). The corresponding graded algebra \( \text{gr} U(\mathfrak{g}_{N}) \) is isomorphic to the symmetric algebra \( S(\mathfrak{g}_{N}) \) of the space \( \mathfrak{g}_{N} \). Elements of \( S(\mathfrak{g}_{N}) \) can be naturally identified with polynomials in matrix elements of an \( N \times N \) matrix \( x = (x_{ij})_{i,j=-n}^{n} \) such that \( x^{t} = -x \). Denote by \( P_{M}(N) \) the subalgebra of the elements of \( S(\mathfrak{g}_{N}) \) which are invariant under the adjoint action of the Lie algebra \( \mathfrak{g}_{N-M} \). The algebra \( A_{M} \) possesses a natural filtration induced by the canonical filtrations on the centralizers \( A_{M}(N) \). The corresponding graded algebra \( \text{gr} A_{M} \) is naturally isomorphic to the projective limit \( P_{M} \) of the commutative algebras \( P_{M}(N) \) with respect to homomorphisms \( P_{M}(N) \to P_{M}(N-2) \) analogous to (5.1); see [15, Section 4]. The images in \( P_{M}(N) \) of the coefficients the series (5.2) and (5.3) can be found from the explicit formulas for the Sklyanin minors; see Proposition 5.6. Indeed, apply the proposition to the Sklyanin minor \( s^{-n}\cdots-m-1,m+1\cdots n \ (u+n-m) \) then replace each series \( s_{ij}(u) \) by its image \( f_{ij}(u) \) under the evaluation homomorphism \( \psi \). Observe that the image of \( s_{ij}(u) \) coincides with \( f_{ij}(u+1) \). Since we are only interested in the highest degree component of the coefficient at each power of \( u^{-1} \), we may replace each expression of type \( f_{ij}(u+c) \) by \( \delta_{ij} + F_{ij} u^{-1} \). Hence, denoting the elements...
of the set \( \mathcal{A} = \{-n, \ldots, -m - 1, m + 1, \ldots, n\} \) by \( a_1, \ldots, a_{N-M} \) we can write, modulo lower degree terms at each power of \( u \),

\[
f^{-a_1 \cdots -a_{N-M}}(u + n - m) = \alpha_{n-m}(u + n - m)
\]

\[
\times \sum_{p \in \mathcal{S}_M} \text{sgn} \, pp' \cdot (1 + F u^{-1})^{-a_{p(1)}} \cdots (1 + F u^{-1})^{-a_{p(N-M)}},
\]

where \( F \) denotes the \( (N - M) \times (N - M) \) matrix whose rows and columns are enumerated by the elements of the set \( \mathcal{A} \) and whose \( ij \)-th entry is \( F_{ij} \). Since these matrix elements commute modulo lower degree terms, taking into account the relation

\[
\alpha_{m-n}(u) \alpha_{n-m}(u + n - m) = 1,
\]

we can conclude from Lemma 3.8 that the image of the series (5.2) in \( P_M(N) \) is the determinant \( \det(1 + x u^{-1})_{\mathcal{A},\mathcal{A}} \). The same argument shows that the image of the series (5.3) in \( P_M(N) \) is \( \det(1 + x u^{-1})_{\mathcal{A},\mathcal{A}_i}, \) where

\[
\mathcal{A}_i = \{-n, \ldots, -m - 1, i, m + 1, \ldots, n\}.
\]

Our next step is to show that every element \( \phi \) of the algebra \( P_M(N) \) such that \( \deg \phi < n - m \) can be represented as a polynomial in the coefficients of the series \( \det(1 + x u^{-1})_{\mathcal{A},\mathcal{A}} \) and \( \det(1 + x u^{-1})_{\mathcal{A},\mathcal{A}_i} \). However, it was proved in [14, Section 4.9] that \( \phi \) can be presented as a polynomial in the elements \( \text{tr} (x_{\mathcal{A},\mathcal{A}})^k \) and \( \Lambda_{ij}^{(k)} \) with \(-m \leq i, j \leq m \) and \( k \geq 1 \), where \( \Lambda_{ij}^{(k)} = \sum x_{c_1 c_2 \cdots c_k - ij} \), summed over the indices \( c_r \in \mathcal{A} \). On the other hand, each element \( \text{tr} (x_{\mathcal{A},\mathcal{A}})^k \) is a polynomial in the coefficients of the series \( \det(1 + x u^{-1})_{\mathcal{A},\mathcal{A}} \). This follows from the fact that the coefficients of the characteristic polynomial \( \det(u + x)_{\mathcal{A},\mathcal{A}} \) form a complete set of invariants of the matrix \( x_{\mathcal{A},\mathcal{A}} \). (Explicit expressions for the elements \( \text{tr} (x_{\mathcal{A},\mathcal{A}})^k \) in terms of the coefficients of the characteristic polynomial can be derived e.g. from the Liouville formula; cf. [14, Remark 5.8]). The claim now follows from the well known identity

\[
\det(1 + x u^{-1})_{\mathcal{A},\mathcal{A}_i} = \det(1 + x u^{-1})_{\mathcal{A},\mathcal{A}} \cdot \left( \delta_{ij} + \sum_{k=1}^{\infty} (-1)^{k-1} \Lambda_{ij}^{(k)} u^{-k} \right); \quad (5.4)
\]

see e.g. [6][7]. Indeed, the identity implies that the elements \( \Lambda_{ij}^{(k)} \) are polynomials in the coefficients of the series \( \det(1 + x u^{-1})_{\mathcal{A},\mathcal{A}} \) and \( \det(1 + x u^{-1})_{\mathcal{A},\mathcal{A}_i} \). This allows us to conclude that the algebra \( \Lambda_M \) is generated by the subalgebra \( C_M \) and the image of the homomorphism \( \psi \).

Observe that since the matrix \( x \) satisfies \( x^t = -x \) we have the relations

\[
\det(1 + x u^{-1})_{\mathcal{A},\mathcal{A}} = \det(1 - x u^{-1})_{\mathcal{A},\mathcal{A}}
\]

and

\[
\Lambda_{ij}^{(k)} = (-1)^k \theta_{ij} \Lambda_{-j,-i}^{(k)}.
\]
Hence, we can write
\[
\det(1 + xu^{-1})_{AA} = 1 + \sum_{r=1}^{\infty} \Lambda(2r) u^{-2r}
\]
for some polynomials \(\Lambda^{(2r)}\) in the matrix elements of \(x\). For the elements \(\Lambda^{(k)}_{ij}\) we shall impose the following restrictions on \(i,j,k\):
\[
i + j < 0 \text{ for } k \text{ odd, } \quad i + j \leq 0 \text{ for } k \text{ even}
\]
in the orthogonal case, and
\[
i + j < 0 \text{ for } k \text{ even, } \quad i + j \leq 0 \text{ for } k \text{ odd}
\]
in the symplectic case. Fix a positive integer \(K\) and assume that the index \(k\) satisfies \(1 \leq k \leq K\). It follows from the argument of [15, Section 4.10] that there exists a large enough value of \(N\) such that the polynomials \(\Lambda^{(k)}\) for even \(k\), and \(\Lambda^{(k)}_{ij}\) with the above restrictions on \(i,j,k\) are algebraically independent. Due to the identity (5.4), the same statement will hold if each polynomial \(\Lambda^{(k)}_{ij}\) is replaced by the coefficient at \(u^{-k}\) of the series \(\det(1 + xu^{-1})_{A_iA_j}\). This proves the injectivity of \(\psi\) and the tensor product decomposition for the algebra \(A_M\). \(\square\)
