Price Discrimination with Loss Averse Consumers*

March 2015

Abstract

This paper proposes a theory of price discrimination based on consumer loss aversion. A seller offers a menu of bundles before a consumer learns his willingness to pay, and the consumer experiences gain-loss utility with reference to his prior (rational) expectations about contingent consumption. With binary consumer types, the seller finds it optimal to abandon screening under an intermediate range of loss aversion if the low willingness-to-pay consumer is sufficiently likely. We also identify sufficient conditions under which partial or full pooling dominates screening with a continuum of types. Our predictions are consistent with several observed practices of price discrimination.

JEL Classification: D030, D42, D82, D86, L11

Keywords: Reference-dependent preferences, loss aversion, price discrimination, personal equilibrium, preferred personal equilibrium.

1 Introduction

When facing heterogeneous buyers, price discrimination allows a seller to capture a larger portion of the total market surplus than offering a single product quality. Price discrimination is prevalent but sellers often employ just a small number of product types, despite our casual and statistical observations that suggest significant heterogeneity among buyers’ willingness to pay. The lack of sufficient product variety has been commonly attributed to the existence of some fixed costs of launching products of different qualities (e.g. Dixit and Stiglitz (1977), Spence (1980)). In many instances, however, these costs tend to be small or immaterial thereby making it difficult to justify the observed patterns of firm strategy by resorting to such costs alone.

One application that illuminates the case in point is ticket pricing in the entertainment markets. The seats in existing venues provide different views and the cost of offering multiple seating categories is essentially zero. But, the practice of price discrimination in this industry, sometimes known as “scaling the house,” displays wide variations both within and across markets as well as across time (see the survey of Courty (2000)). In particular, many ticket sellers indeed choose to offer uniform pricing or very few seating categories. ¹ Movie theaters usually offer a single seat category.

Leslie (2004) investigates the revenue impact of price discrimination at a single Broadway play and observes that almost 75% of the performances offered just two seating categories with the remainder offering three. In a large panel dataset on US pop music concerts analyzed by Courty and Pagliero (2012a,b), two categories were used by more than half of the sample and another quarter came with single price ticketing. In a study of another industry with potentially low fixed product costs, Crawford and Shum (2007) report that 70% of over 1000 US cable TV providers in their sample year of 1995 offered a single package of channels only. Given the substantial returns to multiple products estimated by the authors, these observations pose something of a puzzle as to why the sellers fail to fully exploit the profit potential of price discrimination.

In this paper, we address this gap between the observed patterns and existing theories of price discrimination by developing an alternative theory that incorporates a now well-established bias from rational decision making, namely, consumer loss aversion (Kahneman and Tversky (1979)). The basic intuition is simple: with reference-dependent preferences,

¹Seats in entertainment venues that offer a uniform price are usually allocated on the first-come-first-served basis, and hence, the customers can be thought of as facing a single, random seat quality.
screening certain types of consumers would lead them to experience an asymmetrically large utility loss relative to their reference points and as a consequence the firm would have to meet additional costs to satisfy the incentive constraints needed for screening.

Specifically, we introduce Kőszegi and Rabin’s (2006) expectation model of reference-dependent preferences into a standard screening model à la Mussa and Rosen (1978). In our setup, a monopolist seller offers a menu of bundles before a buyer privately observes his willingness to pay and decides whether or not to make a purchase. As in Kőszegi and Rabin (2006), henceforth referred to as KR, the buyer anticipates his future consumption choice for each possible contingency and experiences “gain-loss utility” with reference to his own past expectation of contingent consumption, in addition to standard “consumption/intrinsic utility.” Furthermore, the expectation must be correct; that is, it must be consistent with the buyer’s optimal consumption choice in each realization of uncertainty. This requirement of rational expectation, or personal equilibrium (PE), implies that the menu must satisfy incentive compatibility and (ex post) participation constraints that account for reference-dependent preferences and loss aversion.

In addition to the large existing literature documenting empirical support for loss aversion in a variety of economic situations, a slew of recent studies point to the specific role played by expectations in the formation of reference points (e.g. Mas (2006), Abeler, Falk, Götte and Huffman (2011), Card and Dahl (2011), Crawford and Meng (2011), Ericson and Fuster (2011), Sprenger (2011), Gill and Prowse (2012)). The price discrimination setting offers a natural ground to explore the expectation-based approach to reference point formation, because its essential ingredient is the uncertainty of consumer demand. We usually know products that are available before discovering the specific conditions that determine our preferences. Consider a sports fan whose willingness to pay for the sports TV package is influenced by the performance of his favorite team during pre-season. This consumer may form an expectation that he would purchase the premium package if and only if the favorite team ends up having a promising pre-season. But, once the regular season starts, he compares the expected purchase to what he could have consumed.

We show that loss aversion indeed serves to limit the benefits of price discrimination and can even result in the optimality of a full pooling menu in a situation where buyers

\footnote{Kőszegi and Rabin (2007, 2009) extend their previous model to incorporate risky and intertemporal decisions. Other models of expectation-based reference-dependent preferences are analyzed by Bell (1985), Loomes and Sugden (1986), Gul (1991) and Shalev (2000).}

\footnote{Our main results also hold under alternative timelines with ex ante participation and therefore can be applied to a variety of applications. See Section 5.2.}
with standard preferences would be separated via a menu with strictly increasing quality-price schedule. Moreover, the expectation-based approach brings into play an additional determinant of optimal contractual form: it depends on an interplay between the extent of consumer loss aversion and the shape of the distribution of consumer’s willingness to pay, offering a new perspective on how to interpret the variations in the degree of price discrimination observed in the real world. In particular, our results suggest that given a (sufficient) level of loss aversion, the firm is more likely to shy away from screening in markets with large population of consumers with low willingness to pay.

Consistent with this finding, in contrast to pop concerts, high-brow entertainment events, such as classical concerts, usually offer many seating categories (e.g. Huntington (1993)); in their cross-section study of cable TV providers, Crawford and Shum (2007) report evidence that markets offering more cable packages tend to be “populated by households with greater tastes for cable service quality (p.201, Crawford and Shum (2007)).” Our predictions can also shed light on observed pricing practices in other industries. For example, buses and motels usually offer a single type of seats and rooms, and this contrasts with the standard features of trains and hotels that frequently serve upscale travelers.

Our main message is most clearly conveyed in the case of binary consumer types, where the effect of loss aversion manifests itself in two ways. First, when each consumer compares the alternative of non-participation to the bundle of his choice ex post, he experiences a loss on quality and a gain in money. Thus, as the consumer becomes more loss averse, he becomes willing to pay more for a given quality, which implies that the seller can profitably increase the quality for the type whose participation constraint is binding (i.e. the low willingness-to-pay type).

Second, for the consumer who acquires an information rent (i.e. the high willingness-to-pay type), deviation to lower quality-price bundle leads to another channel of gain-loss comparisons across the two utility dimensions. In this case, however, the comparison is weighted by the ex ante likelihood of the alternative event. Given loss aversion, the deviation incentive would be greater when the low willingness-to-pay type, and thus a lower price, was anticipated with a larger probability. The combination of the above two effects generates the following: when the likelihood of low willingness-to-pay consumer is sufficiently large and the degree of loss aversion lies in an intermediate range, the seller’s optimal strategy is to offer the same bundle to both types.\footnote{\textsuperscript{4}When the buyer is very loss averse, a reverse-screening menu, where the low consumer type purchases a}
In our model, multiple personal equilibria may arise from a menu. Our treatment above follows the standard mechanism design approach by assuming that the firm can select the PE and hence focusing on truthful self-selection. An alternative approach suggested by KR is to assume that it is the consumer who is capable of choosing his favorite PE, or the preferred personal equilibrium (PPE). We derive the optimal menu under the concept of PPE and binary consumer types, and show that a pooling menu continues to be optimal under a wide range of parameter values. To our knowledge, this is the first non-trivial analysis of PPE in a model of adverse selection to date.

In another extension, we incorporate a continuum of consumer types into the analysis. Here, focusing on the case in which full separation is optimal under standard preferences, we establish conditions under which partial or even full pooling is optimal among menus with monotone quality and price.

Our paper contributes to the growing literature on firm behavior under boundedly rational agents (see the surveys of Ellison (2006), Spiegler (2011), Köszegi (2014)). Among this literature, monopolist’s screening problems with loss averse consumers have recently been studied independently by Herweg and Mierendorff (2013) and Cabarjal and Ely (2014).

Herweg and Mierendorff (2013) consider a seller who chooses from two-part tariffs for a loss averse consumer with uncertain demand and demonstrate the optimality of flat tariff. They model the consumer also in the frame of KR but gain-loss utilities arise only in the money dimension. In contrast, we assume gain-loss utilities arising from both money and quality dimensions while allowing for menu contracts and a variety of participation timelines. Also, in our setup with menus, the issue of multiple personal equilibria becomes relevant. Our results show that loss aversion can lead to bunching over quality as well as price.

In Cabarjal and Ely (2014), the seller offers a menu to a consumer who already knows his type and admits an exogenously given reference point that is type-dependent. The consumer exhibits reference-dependent preferences only with respect to quality consumption. In terms of results, their main concern is to explain how the shape of optimal contract depends on the precise form of the reference point.

Loss aversion has been fruitfully incorporated in other contexts of firm behavior. Heidhues and Köszegi (2014), Spiegler (2012) and Rosato (2013) consider monopoly pricing with complete information. In these models, the monopolist can optimally commit to a random higher quality-price bundle than the high consumer type, can be made incentive feasible and even optimal. However, this result does not hold when there is a continuum of types. See Section 5.1.
pricing strategy. In contrast, we explore the role of loss aversion in a model with demand uncertainty and menu contracts. The consumer’s expectations concern his future demand, not the price realization. Also using the KR model, Heidhues and Kőszegi (2008) explain why firms with differentiated products and heterogeneous costs may end up charging a uniform price. The competition model of differentiated products is also explored by Karle and Peitz (2013) and Zhou (2011). De Meza and Webb (2007) and Herweg, Müller and Weinschenk (2010) study the role of loss aversion in agency problems. In auctions, loss averse bidders are introduced by Eisenhuth (2010), and Grillo (2013) considers a cheap talk game in which the receiver is loss averse.

Finally, our paper complements other approaches aimed at understanding the implications of biased consumers for monopolist behavior. Time-inconsistent preferences or self-control problems have been explored in the context of contract design by DellaVigna and Malmendier (2004), Eliaz and Spiegler (2006), Esteban, Miyagawa and Shum (2007) and Heidhues and Kőszegi (2010); Eliaz and Spiegler (2008) and Grubb (2009)) investigate the role of overconfident consumers.

This paper is organized as follows. Section 2 lays out a price discrimination setup with KR’s reference-dependent preferences for the binary-type case. In Section 3 we characterize the optimal menu in our model by adopting truthful personal equilibrium as the solution concept. The optimal menu under preferred personal equilibrium is characterized in Section 4. We offer several extensions in Section 5, including an analysis of a continuum of consumer types. Section 6 concludes. All proofs are relegated to the Appendix unless mentioned otherwise. We also present the details of some omitted analyses in a Supplementary Material.

2 The Setup

2.1 Price Discrimination with Loss Averse Consumers

Consider a market that consists of a monopolistic seller of some product and its buyer. Let \( b = (q, t) \) denote a “bundle” in which the product of quality \( q \) is sold for the payment of \( t \), and let \( \emptyset = (0, 0) \) denote the null bundle or outside option. The seller’s profit from a bundle \( b = (q, t) \) is \( t - cq \), where \( c > 0 \) is the constant marginal cost of production. There is no cost of offering a bundle.

We assume that the buyer has reference-dependent preferences, which consist of “con-
sumption (or intrinsic) utility” and “gain-loss utility.” First, the buyer’s consumption utility from a bundle \( b = (q, t) \) is given by

\[ m(b; \theta) := \theta v(q) - t, \]

where \( \theta \) is a measure of willingness-to-pay and \( v(\cdot) \) is a (differentiable) function satisfying \( v(0) = 0, v'(\cdot) > 0, v''(\cdot) < 0, \lim_{q \to 0} v'(q) = \infty \) and \( \lim_{q \to \infty} v'(q) = 0 \). We assume that \( \theta \) is randomly drawn and becomes privately known to the buyer when it is realized. For now, \( \theta \) is assumed to take binary values, \( \theta_L > 0 \) and \( \theta_H > \theta_L \) with probability \( p \in (0, 1) \) and \( 1 - p \), respectively. Later in Section 5.1, we will consider a continuum of types.\(^5\)

Next, we explain the gain-loss utility. The situation we have in mind is as follows. The seller commits to a menu of bundles, \( M \), which is observed by the buyer before his willingness-to-pay, \( \theta \), is known. The buyer then anticipates his choice of bundle for each possible contingency of the realization of his type, and this expectation serves as his reference point when actual consumption takes place after the uncertainty becomes resolved. We will later require that this expectation be consistent with the buyer’s actual choice; that is, the expectation should be rational.

The following timeline will be useful to illustrate the model and compare it with the standard screening model.

\[ \text{Time} \]
\[ \begin{align*}
\text{The seller offers a menu;} & \quad \theta \text{ realized} & \quad \text{The buyer chooses/consumes} \\
\text{The buyer forms a reference point} & \quad \text{a (no) bundle from the menu}
\end{align*} \]

In the standard contract theory, the type parameter \( \theta \) usually represents the agent’s inherent preference for consumption which is realized and privately observed prior to the contracting stage. In our setup, \( \theta \) can be interpreted as a random utility component that becomes known to the buyer only when the uncertainty, which determines the buyer’s willingness to pay, gets resolved around the time of consumption. Prior to learning \( \theta \) and making the actual purchase, the buyer has time to observe the seller’s menu already existing in the market (and possibly being bought by other buyers) and forms a contingent consumption plan that will serve as reference point. As argued in the Introduction, we consider the above timeline as plausible in many real-world situations.

\(^5\)The consumer in our model has vertically differentiated tastes for quality. We also consider the implications of loss aversion in the model with horizontal demand heterogeneity. See Section 5.3.
Formally, let \( r_i = (q_r^i, t_r^i) \) denote the bundle that the buyer expects to choose if his type is realized to be \( \theta_i, i = H, L \). Given \( R := \{r_L, r_H\} \), type-\( \theta \) buyer’s gain-loss utility from a bundle \( b = (q, t) \) takes the following form:

\[
n(b; \theta, R) := p[\mu(\theta v(q) - \theta_L v(q_L^r)) + \mu(t_r^L - t)] + (1 - p)[\mu(\theta v(q) - \theta_H v(q_H^r)) + \mu(t_r^H - t)],
\]

(1)

where \( \mu \) is an indicator function such that, for any \( k_1, k_2 \in \mathbb{R}_+ \),

\[
\mu(k_1 - k_2) := \begin{cases} 
  k_1 - k_2 & \text{if } k_1 \geq k_2 \\
  \lambda(k_1 - k_2), \lambda > 1 & \text{if } k_1 < k_2.
\end{cases}
\]

To explain our formulation, consider the term \( \mu(\theta v(q) - \theta_L v(q_L^r)) \) in the RHS of (1), for instance. This captures type \( \theta \)’s gain-loss utility from consuming quality \( q \) relative to state \( \theta_L \), which is then weighted by the probability \( p \) with which the buyer had expected \( \theta_L \) to occur. Note that the consumer in our model experiences gain-loss from the difference in the final utilities that he would obtain across two states. The parameter \( \lambda \) measures the degree of loss aversion.

Following Tversky and Kahneman (1991) and K˝oszegi and Rabin (2006), we assume that the gain-loss utility is additively separable across the two consumption dimensions, quality and monetary transfer.\(^7\) Given the reference point \( R \) (expected choices of bundles), a type-\( \theta \) buyer’s overall utility from \( b = (q, t) \) is the sum of consumption and gain-loss utilities:\(^8\)

\[
u(b; \theta, R) := m(b; \theta) + n(b; \theta, R).
\]

### 2.2 Personal Equilibrium

We now introduce the notion of *personal equilibrium* proposed by KR, which incorporates the idea that the reference point formed by an economic agent should be in accordance with

\(^6\)When we write a menu as an ordered pair of two bundles, the first (second) element refers to the bundle consumed by the low (high) type. When the two elements are the same and equal to \( r \), with slight abuse of notation, we sometimes write the corresponding menu simply as \( \{r\} \).

\(^7\)The additive separability of gain-loss utility is consistent with the *endowment effect* observed in many empirical studies. An alternative formulation would be to apply the gain-loss utility to the total utility, \( \theta v(q) - t \). It turns out that the predictions of our model under such a gain-loss specification are no different from the model with standard preferences. See Section S.7 of the Supplementary Material.

\(^8\)To adjust the magnitude of gain-loss utility relative to consumption utility, we could introduce a parameter, say \( \beta \), and multiply it to the gain-loss utility term. Here, we set \( \beta \) equal to 1 for simplicity; the qualitative features of our results remain the same for any \( \beta \) provided it is not too small.
his actual choices.

**Definition 1.** Given any menu $M$, $R = \{r_i\}_{i=H,L} \subseteq M \cup \{\emptyset\}$ is a personal equilibrium (PE) if

$$u(r_i|\theta_i, R) \geq u(b|\theta_i, R), \forall b \in M \cup \{\emptyset\}, \forall i = H, L. \tag{2}$$

We say that $R = \{r_i\}_{i=L,H}$ is a truthful personal equilibrium (TPE) if it is a PE given $M = R$.

Condition (2) requires that each bundle $r_i$ in the PE be optimal for type $\theta_i$ with $R$ as the reference point so that $r_i$ is the bundle the buyer actually chooses if his type turns out to be $\theta_i$. Note that the equilibrium utility of each type must be no lower than its utility from choosing the null option since the buyer can always opt out after the realization of his type.

In the case of a TPE, the reference point itself is offered as a menu and therefore each type only needs to prefer his choice of bundle over the other type’s bundle or the null bundle. That is, $R = \{r_i\}_{i=L,H}$ is a TPE if and only if the incentive compatibility and individual rationality requirements hold as follows: for each $i = H, L$,

$$u(r_i|\theta_i, R) \geq u(r_{-i}|\theta_i, R) \quad (IC_i)$$

$$u(r_i|\theta_i, R) \geq u(\emptyset|\theta_i, R). \quad (IR_i)$$

Since these inequalities, henceforth referred to as the $(IC)$ and $(IR)$ constraints, are implied by (2), the following result is immediate.

**Proposition 1.** Suppose $R = \{r_i\}_{i=L,H}$ is a personal equilibrium (PE) of some menu $M$. Then, $R$ is a truthful personal equilibrium (TPE).

This result is a version of revelation principle since it implies that it is without loss to focus on direct menus, i.e. menus in which every bundle is purchased in equilibrium.

The concept of personal equilibrium is not robust to the problem of multiple equilibria, however. When the seller offers a TPE menu $R = \{b_L, b_H\}$, the buyer might form an alternative reference point $R' \neq R$ and play it as a PE so that the seller fails to achieve the desired outcome. Moreover, the alternative PE could give the buyer a higher ex ante expected utility than the TPE. It is possible that the TPE generates a negative ex ante utility with there being another PE in which the buyer does not buy at all.

One approach to resolve the issue of multiple PEs proposed by KR is to assume that the consumer always chooses the PE that maximizes his ex ante expected utility, or the *preferred*
personal equilibrium (PPE). Let $\mathcal{P}(M)$ denote the set of all PEs that can arise when the seller offers a menu $M$; that is, $R$ belongs to $\mathcal{P}(M)$ if $R \subseteq M \cup \{\emptyset\}$ and $R$ satisfies condition (2). Also, given a menu $R = \{(q_L, t_L), (q_H, t_H)\}$, let $U(R)$ denote the buyer’s corresponding ex ante expected utility:

$$U(R) := pu(r_L|\theta_L, R) + (1 - p)u(r_H|\theta_H, R).$$

**Definition 2.** Given any menu $M$, $R = \{r_i\}_{i=H,L} \subseteq M \cup \{\emptyset\}$ is a preferred personal equilibrium (PPE) if $R \in \mathcal{P}(M)$ and $U(R) \geq U(R')$ for all $R' \in \mathcal{P}(M)$. We say that $R = \{r_i\}_{i=L,H}$ is a truthful preferred personal equilibrium (TPPE) if it is a PPE given $M = R$.

We characterize the seller’s profit-maximizing menu of bundles under both notions PE and PPE. In Section 3, the seller is assumed to be able to select his favorite PE from the menu that he offers; in Section 4, the buyer selects the PPE. While it may be unrealistic to assume that the seller can always manipulate the consumer’s beliefs, it also seems plausible that some consumers would respond naively to the menu on the table when he forms beliefs about his future contingent actions.

In both treatments, we restrict attention to the set of direct menus by focusing on TPE and TPPE. This is without loss for the analysis of PE menu due to Proposition 1, but a similar revelation principle for PPE menus may not hold. To see this, suppose that $R$ is a PPE given some menu $M \neq R$. It is possible that $R$ is not a PPE given itself—that is, $R$ is not a TPPE—because we cannot a priori rule out existence of some $R' \in \mathcal{P}(R)$ that does not belong to $\mathcal{P}(M)$ and generates a higher ex ante expected utility. This failure of revelation principle poses a great challenge for a complete analysis of optimal menu design since such analyses rely critically on the revelation principle, as well known from the mechanism design literature. Later (in Remark 2), we will offer a discussion on the strength of our results on optimal TPPE menus.9

---

9We also consider an alternative model of consumer preference in which the reference point is given by the fixed expected utility of a given menu instead of the KR formulation of stochastic consumption plan. See Section 5.4.
3 Optimal TPE Menu

3.1 The Seller’s Problem

Proposition 1 implies that the set of PE menus is equivalent to the set of TPE menus and hence there is no loss in restricting ourselves to menus that are themselves TPEs. We sometimes refer to such a menu simply as a TPE menu and let \( \mathcal{M} \) denote the set of all TPE menus. The seller’s problem, denoted as \([P]\), is given by

\[
\max_{\{q_L, t_L, q_H, t_H\} \in \mathcal{M}} p(t_L - cq_L) + (1 - p)(t_H - cq_H). \quad [P]
\]

Under the reference-dependent preference framework, a broader class of menus can be supported as TPEs, compared to the standard screening model. In particular, it is possible to have the low-type buyer purchasing the higher quality-price bundle and vice versa. Given such a menu, the high type suffers a loss from deviating to mimic the low type and paying more than anticipated, and this no longer supports the usual incentive compatibility argument for the necessity of quality monotonicity of a feasible menu.

One class of menus that can be easily ruled out is one where one type of buyer receives a lower quality but pays more than the other type (including the case of a higher payment for the same quality or the same payment for a lower quality). The reason is simple: if the former type deviates to the latter’s bundle, then he will enjoy a higher gain-loss utility as well as a higher intrinsic utility.

We are therefore left with the following three classes of menus to consider.

1. **Pooling menu**: \( q_H = q_L \) and \( t_H = t_L \)

2. **Screening menu**: \( q_H > q_L \) and \( t_H > t_L \)

3. **Reverse-screening menu**: \( q_H < q_L \) and \( t_H < t_L \)

We let \( \mathcal{M}^P \), \( \mathcal{M}^S \) and \( \mathcal{M}^R \) denote the set of pooling, screening and reverse-screening menus, respectively, that satisfy the \((IC)\) and \((IR)\) constraints. For the full expressions of these constraints, see Section S.1 of the Supplementary Material.
3.2 Symmetric Information Benchmark

Before the main analysis, we examine the optimal menu when the seller and buyer are symmetrically informed. This will give us an insight into how the informational asymmetry interacts with loss aversion to generate the optimality of pooling. Consider a profit-maximizing seller who is symmetrically informed of $\theta$ and thus can commit to a menu ex ante such that she imposes $(q_i, t_i)$ upon observing each type $\theta_i$ being realized. Specifically, we modify the seller’s problem $[P]$ by dropping the (IC) constraints. Let us denote by $[P^s]$ the seller’s profit maximization problem among contracts that satisfy the (IR) constraints only.

The following result gives a necessary condition for the optimal menu with symmetric information.

**Lemma 1.** The solution to $[P^s]$ must be such that $\theta_H v(q_H) \geq \theta_L v(q_L)$ and $t_H \geq t_L$.

Using the above Lemma and the fact that both (IR) constraints are binding, we obtain

$$t_L = \frac{(\lambda + 1)}{2} \theta_L v(q_L) \quad \text{and} \quad t_H = t_L + \frac{\theta_H v(q_H) - \theta_L v(q_L)}{B(p, \lambda)},$$

where

$$B(p, \lambda) := \frac{1 + (1 - p) + p\lambda}{1 + p + (1 - p)\lambda}.$$  

Here, $B(p, \lambda)$ measures the relative impact of loss aversion on deviation incentives in our model, where gain-loss utilities arise stochastically in both quality and monetary dimensions. Deviating from purchasing the reference bundle to the null bundle induces a loss in quality but a gain in money. Notice that $B(p, 1) = 1$.

Assuming $\theta_H v(q_H) > \theta_L v(q_L)$ at the optimum,\(^{10}\) we can plug (3) into the objective function and take the first-order conditions to obtain

$$\frac{c}{v'(q_L)} = \frac{((\lambda + 1)B(p, \lambda) - 2(1 - p))\theta_L}{2pB(p, \lambda)},$$

and

$$\frac{c}{v'(q_H)} = \frac{\theta_H}{B(p, \lambda)}.$$  

Note from (5) and (6) that $q_L \geq q_H$ if and only if

$$\frac{(\lambda + 1)B(p, \lambda) - 2(1 - p)}{2p} \geq \frac{\theta_H}{\theta_L},$$

\(^{10}\)It is possible to have $\theta_H v(q_H) = \theta_L v(q_L)$ at the optimum. We ignore this case to ease the exposition.
which holds for $\lambda$ exceeding some threshold since $(\lambda+1)B(p,\lambda)$ strictly increases in $\lambda$ without bound. Thus, with $\lambda$ high enough to satisfy (7), the symmetrically informed seller can maximize profit by endowing the low type with a higher quality but charging the high type with a larger transfer (see (3)). Note that the optimal qualities are the same across the two types only when (7) holds as equality, which is a knife-edge phenomenon. Furthermore, the same quality does not necessarily mean the same transfer.

This implies that pooling menu, which is the main focus of our analysis, does not arise when the buyers are loss averse but do not hold private information. Neither does it emerge as a consequence of asymmetric information alone, as in Mussa and Rosen (1978). The optimality of pooling is indeed a consequence of the interplay between loss aversion and asymmetric information, as we demonstrate in later sections. Intuitively, pooling will emerge as the optimal menu when the quality reversal is desirable due to loss aversion but is not feasible in the presence of asymmetric information.

3.3 Results

We now turn to the analysis of $[P]$, i.e. finding an optimal menu when the seller and buyer are asymmetrically informed. A unified analysis of all possible menus is not available since different classes of menus entail different forms of gain-loss utility. Our analysis below considers each class separately to identify an optimal menu within that class, which will then lead us to characterize the overall optimal menu. Note that any pooling menu lies on the boundary of the set of feasible screening menus ($\mathcal{M}^S$) or reverse-screening menus ($\mathcal{M}^R$). The optimality of pooling will thus arise if two inequality constraints, $q_H \geq q_L$ and $q_H \leq q_L$, which we impose to find an optimal menu within $\mathcal{M}^S$ and $\mathcal{M}^R$, turn out to be binding. In what follows, whenever we mention an “optimal screening (pooling or reverse-screening) menu,” it will mean optimality within the set of screening (pooling or reverse-screening) menus.

3.3.1 Pooling Menu

We begin by characterizing the seller’s profit-maximizing choice within the class of the pooling menu. Consider a pooling menu $R = \{r = (q, t)\} \in \mathcal{M}^P$. Clearly, the $(IR_H)$ constraint is implied by the $(IR_L)$ constraint since, if both types choose the same bundle, type $\theta_H$ is better off in terms of both intrinsic and gain-loss utilities while the outside payoff is type-
independent. Now, \((IR_L)\) can be written as

\[
u(r|\theta_L, R) = \theta_L v(q) - t - (1 - p)\lambda(\theta_H - \theta_L)v(q) \\
\geq u(\emptyset|\theta_L, R) = p[t - \lambda \theta_L v(q)] + (1 - p)[t - \lambda \theta_H v(q)],
\]

or after rearrangement,

\[
t \leq \frac{(\lambda + 1)}{2} \theta_L v(q).
\]  

(8)

Clearly, (8) must be binding at the optimum. The following result is then immediate from the first-order condition of the seller’s profit-maximization.

**Proposition 2.** The optimal pooling menu, \(\{(q^p, t^p)\}\), is such that \(\theta_L v'(q^p) = \frac{2c}{\lambda+1}\).

Thus, the seller finds it optimal to sell a higher quality to a consumer with higher \(\lambda\). This is because the buyer wants to avoid the loss from non-participation and, therefore, is willing to pay more for a given amount of consumption if he is more loss averse, as can be seen in (8) above.

### 3.3.2 Screening Menu

Consider a screening menu \(R = \{r_L = (q_L, t_L), r_H = (q_H, t_H)\} \in \mathcal{M}^S\) where \(q_L < q_H\) and \(t_L < t_H\). As in the standard screening model, we can show that the \((IC_H)\) and \((IR_L)\) constraints are binding at the optimum while the other constraints are not. Using a similar derivation to (8), the \((IR_L)\) constraint can be written as

\[
t_L \leq \frac{\lambda + 1}{2} \theta_L v(q_L),
\]  

(9)

which must be binding at the optimum. Thus, for the same reason as in the optimal pooling menu above, the optimal quality for the low type increases with loss aversion. We refer to this as the *participation effect* of loss aversion, meaning that a greater aversion to the loss resulting from comparison with non-participation enables the seller to charge more and thus increase the quality for the low type consumer.

Next, write the \((IC_H)\) constraint as

\[
u(r_H|\theta_H, R) = \theta_H v(q_H) - t_H + p[\theta_H v(q_H) - \theta_L v(q_L) - \lambda(t_H - t_L)]
\]
\[
\geq u(r_L|\theta_H, R) = \theta_H v(q_L) - t_L + p(\theta_H - \theta_L)v(q_L) \\
+ (1 - p)[(t_H - t_L) - \lambda \theta_H(v(q_H) - v(q_L))],
\]

which can then be rewritten as

\[
[1 + (1 - p) + p\lambda](t_H - t_L) \leq [1 + p + (1 - p)\lambda]\theta_H[v(q_H) - v(q_L)]. \tag{10}
\]

The benefit of type \(\theta_H\) deviating to \(r_L\), captured by the LHS of (10), consists of reduced payment, \(t_H - t_L\), and its positive impact on the gain-loss utility, \((1 - p + p\lambda)(t_H - t_L)\). To understand the latter, note first that the gain from paying \(t_L\) instead of \(t_H\) is weighted by the probability \(1 - p\) with which the buyer expected the payment to be \(t_H\). At the same time, by the deviation, the high type avoids the loss equal to \(\lambda(t_H - t_L)\) that he would have incurred from sticking with his equilibrium choice, which is weighted by the probability \(p\) with which \(\theta_L\) would have occurred. The cost of deviation, captured by the RHS of (10), results from a reduced quality from \(q_H\) to \(q_L\) and can be explained similarly.

Notice from (10) that higher \(\lambda\) amplifies both the benefit and cost of deviation. When binding, (10) can be written as

\[
t_H = t_L + \frac{\theta_H[v(q_H) - v(q_L)]}{B(p, \lambda)}, \tag{11}
\]

where \(B(p, \lambda) = \frac{1 + (1 - p) + p\lambda}{1 + p + (1 - p)\lambda}\) as defined previously in (4). Here, \(B(p, \lambda)\) is derived from the high type consumer’s incentives to deviate from his reference bundle to the cheaper and lower quality bundle, which would result in a monetary gain but a quality loss. If a higher \(\lambda\) makes \(B(p, \lambda)\) larger (smaller), then the loss aversion makes screening less (more) effective in enabling the extraction of more payment from the high type. We will refer to this as the **screening effect** of loss aversion, which could be favorable or adverse to the seller depending on the value of \(p\). Also, (11) implies that, for a fixed \(\lambda\), the effectiveness of screening is decreasing in the likelihood of low type, i.e., \(B(p, \lambda)\) is increasing in \(p\).

Now, we describe the optimal screening menu and compare it with the optimal pooling menu.

**Proposition 3.** (a) The optimal screening menu, \(\{(q^s_L, t^s_H), (q^s_H, q^s_L)\}\), is such that

\[
\frac{c}{v'(q^*_{L})} = \max \left\{ \frac{(\lambda + 1)B(p, \lambda)\theta_L - 2(1 - p)\theta_H}{2pB(p, \lambda)}, 0 \right\} \tag{12}
\]
\[
\frac{c}{v'(q^*_H)} = \frac{\theta_H}{B(p, \lambda)},
\]

where \( q^*_L \), if not equal to 0, increases in \( \lambda \) and \( q^*_H \) decreases (increases) in \( \lambda \) if \( p > \frac{1}{2} \) \((p < \frac{1}{2})\).

(b) Any screening menu is dominated by the optimal pooling menu if and only if

\[
\frac{\theta_H}{\theta_L} \leq \left(\frac{\lambda + 1}{2}\right) B(p, \lambda),
\]

which in turn holds if and only if \( \lambda \geq \lambda_S \) for some threshold \( \lambda_S > 1 \) that decreases in \( p \) and increases in \( \frac{\theta_H}{\theta_L} \).

In part (a) of Proposition 3, the optimal quality \( q_L \) increasing with \( \lambda \) should be expected from the participation effect. The behavior of \( q_H \) is related to the fact that \( B(p, \lambda) \) increases with \( \lambda \) if \( p > \frac{1}{2} \): That is, a higher \( \lambda \) means the adverse (favorable) screening effect if \( p > \frac{1}{2} \) 
\((p < \frac{1}{2})\).

Part (b) states the condition under which pooling dominates screening. The inequality (14) holds when the participation effect, measured by \( \frac{\lambda + 1}{2} \) (see (9) above), is large and/or when the screening effect works against the profitability of screening as \( B(p, \lambda) \) gets large. There are a couple of noteworthy observations here. First, with sufficiently large \( \lambda \), the dominance of pooling over screening remains even when \( p < \frac{1}{2} \) such that the screening effect works favorably for the screening seller. This is because the participation effect dominates the screening effect, namely, \( \frac{\lambda + 1}{2} \) increases with \( \lambda \) faster than \( B(p, \lambda) \) decreases. Second, the threshold, \( \lambda_S \left(p, \frac{\theta_H}{\theta_L}\right) \), is decreasing in \( p \), and this implies that screening is less attractive relative to pooling when the low-type consumers are more abundant. This follows from the fact that a higher (ex ante) likelihood of \( \theta_L \) generates a greater deviation incentive for the high type via the gain-loss utility \((\partial B(p, \lambda)/\partial p > 0)\).

### 3.3.3 Reverse-Screening Menu

Let us consider next a reverse-screening menu \( R = \{r_L = (q_L, t_L), r_H = (q_H, t_H)\} \in \mathcal{M}^R \) such that \( q_L > q_H \) and \( t_L > t_H \), satisfying the (IC) and (IR) constraints. The reverse-screening menu is a useful device to exploit the aforementioned participation effect by giving a higher quality to the low type. Giving a higher quality to the low type, however, may create a deviation incentive for the high type. This incentive can be curbed should the high
type suffer a sufficient loss from a higher deviation price. How this loss is affected by the parameters in our model will determine when the reverse-screening menu is optimal.

We first provide a couple of necessary conditions for reverse-screening menu to be feasible or optimal.

**Lemma 2.** (a) A reverse-screening menu can be a TPE only if

\[
\frac{\theta_H}{\theta_L} \leq \frac{\lambda + 1}{2}. \tag{15}
\]

(b) Any optimal reverse-screening menu must satisfy \( \theta_H v(q_H) \geq \theta_L v(q_L) \).

Part (a) states that loss aversion must be high enough to sustain a reverse-screening menu as a TPE. According to part (b), the seller does not want to reverse the qualities to the extent that the utility from quality consumption is reversed.

We now compare reverse-screening and pooling menus.

**Proposition 4.** Any reverse-screening menu is dominated by the optimal pooling menu if and only if

\[
\frac{\theta_H}{\theta_L} \geq \frac{1 + p + (1 - p)\lambda}{2}, \tag{16}
\]

which in turn holds if and only if \( \lambda \leq \lambda_R \) for some threshold \( \lambda_R \) that increases in \( p \) and \( \frac{\theta_H}{\theta_L} \).

Thus, if \( \lambda \) is large enough to violate (16), reverse-screening in fact dominates pooling. This arises due to the participation effect that makes the increase in \( q_L \), rather than \( q_H \), more effective in extracting surplus. Since the high-type consumer derives a higher level of utility from any given contract and therefore cares less about an improvement in quality than the low-type consumer, the attractiveness of exploiting the high type’s higher marginal intrinsic utility can be outweighed by the participation effect when the consumer is significantly loss averse.

Condition (16) shows that pooling tends to dominate reverse-screening as \( p \) gets larger. The logic is similar to that behind part (b) of Proposition 3: a higher \( p \) makes it more tempting for the high type to deviate. When the realization of the low type has been anticipated to be more likely, under screening, the high type experiences a greater loss from sticking to \( r_H \) that involves a higher payment while, under reverse-screening, the same consumer finds it less costly to deviate to \( r_L \).
3.3.4 Optimal Menu

We are now ready to characterize the menu that maximizes the expected profit among all TPE menus.

**Theorem 1.** There exists some $\hat{p} \in (0, 1)$ such that $\lambda_S \leq \lambda_R$ if and only if $p \geq \hat{p}$. Then, the optimal menu that solves [P] is

(a) a pooling menu if $p \geq \hat{p}$ and $\lambda \in [\lambda_S, \lambda_R]$;
(b) a screening menu if $\lambda < \min\{\lambda_R, \lambda_S\}$;
(c) a reverse-screening menu if $\lambda > \max\{\lambda_R, \lambda_S\}$;
(d) either screening or reverse-screening menu if $p < \hat{p}$ and $\lambda \in [\lambda_R, \lambda_S]$.

**Proof.** First, it is straightforward to see that

$$\lim_{p \to 0} \lambda_S = \infty > \frac{2\theta_H}{\theta_L} - 1 = \lim_{p \to 0} \lambda_R$$

$$\lim_{p \to 1} \lambda_S = 2\sqrt{\frac{\theta_H}{\theta_L}} - 1 < \infty = \lim_{p \to 1} \lambda_R.$$  

Thus, by the mean value theorem and the monotonicity of $\lambda_S$ and $\lambda_R$, we can find $\hat{p} \in (0, 1)$ such that $\lambda_S \geq \lambda_R$ if and only if $p \geq \hat{p}$. Then, parts (a) to (d) of the claim immediately follow from combining part (b) of Proposition 3 and Proposition 4. 

Pooling is optimal if there is enough mass of low types and the consumer is sufficiently, but not too, loss averse. Otherwise, a screening or reverse-screening menu is optimal. In the latter case, there is a region of parameters, as shown in part (d), in which we have not been able to fully sort between screening and reverse-screening menus, but in most cases we expect the screening (reverse-screening) menu to be optimal if $\lambda$ is low (high).

The central message of Theorem 1 is the optimality of pooling. Although reverse screening can be optimal with sufficiently large degree of loss aversion, we later show that this is not robust in a model with a continuum of buyer types (Theorem 3, part (c)). Also, even in the binary-type case, the reverse-screening menu can only be optimal with a very large degree of loss aversion, as demonstrated in Example 1 below.

The following example illustrates how the optimal menu varies with the parameter values. Here, pooling is optimal for a wide range of parameter values, while reverse screening requires $\lambda$ to be larger than 2.\textsuperscript{11}

\textsuperscript{11}Estimates of loss aversion have been obtained in a variety of contexts, ranging from 1.3 to 2.7; see
Example 1. Suppose that $\frac{\partial \mu}{\partial q_L} = 1.5$. Figure 1 divides the space of $(\lambda, p)$ into four regions according to Theorem 1 and illustrates the type of optimal menu in each region.

![Figure 1: Optimal TPE menu](image)

It can be shown, though only numerically, that in the region (d), there is a threshold value of $\lambda$ for each $p$ below (above) which the screening (reverse-screening) menu is optimal. Below dotted line, the optimal screening menu entails exclusion of the buyer with low willingness to pay (see (12) above).\(^{12}\)

Notice in the above example that, at low values of $p$, loss aversion actually generates a benefit from serving also the low type buyer who would otherwise be excluded by the profit-maximizing seller. This is due to the participation effect that enables the firm to sell a higher quality-price bundle to the low type than in the model without loss aversion.\(^{13}\)

\(^{12}\)In the optimal reverse-screening menu, however, neither type is excluded. To see this, note that by definition of reverse screening, $q_L > q_H$, and also that by Lemma 2(b), $q_L > 0$ implies $q_H > 0$.

\(^{13}\)This observation demonstrates an important distinction between our theory and an alternative explanation of coarse price discrimination based on fixed menu costs. In contrast to our predictions, when $p$ is low, menu cost would have no bite since the seller would serve only the high type customers even without it.
4 Optimal TPPE Menu

4.1 The Seller’s Problem

Let us next consider a consumer who is capable of choosing the best PE from a given menu of bundles. We restrict attention to TPPE menus, i.e. TPE menus that generate the highest ex ante utility to the consumer among all corresponding PEs.

Given any TPE menu $R = \{b_L, b_H\} \in \mathcal{M}$, let

$$C(R) := \{R' = \{b'_L, b'_H\} \neq R | b'_i = \emptyset, b_L, \text{ or } b_H \text{ for each } i = L, H\},$$

that is, the set of all menus other than $R$ that can arise from each of the two types choosing a bundle contained in $R$. In order for a TPE menu $R = \{b_L, b_H\}$ to be a TPPE, it must be that for every alternative consumption plan $R' \in C(R)$, either $R'$ fails to be a PE or the buyer’s ex ante payoff from $R'$ does not exceed that from $R$. This requirement will be met if and only if $R$ and $R'$ satisfy at least one of the five inequalities below:

$$u(b'_L|\theta_L, R') < u(\tilde{b}|\theta_L, R') \text{ for } \tilde{b} \in R \setminus \{b'_L\} \quad \text{(FIC}_L)$$
$$u(b'_L|\theta_L, R') < u(\emptyset|\theta_L, R') \quad \text{(FIR}_L)$$
$$u(b'_H|\theta_H, R') < u(\tilde{b}|\theta_H, R') \text{ for } \tilde{b} \in R \setminus \{b'_H\} \quad \text{(FIC}_H)$$
$$u(b'_H|\theta_H, R') < u(\emptyset|\theta_H, R') \quad \text{(FIR}_H)$$
$$U(R') \leq U(R). \quad \text{(U)}$$

Fixing a consumption plan $R$, the first four inequalities above represent violations of the four ($IC$) and ($IR$) conditions, respectively, for an alternative plan $R'$ to constitute itself a PE. These inequalities will be referred to as the ($FIC$) and ($FIR$) conditions. The last inequality means that the buyer’s ex ante payoff from $R'$ does not exceed that from $R$. We say that $R \in \mathcal{M}$ satisfies the PPE requirement with respect to $R'$ if at least one of the above five inequalities is satisfied.

A TPE menu $R \in \mathcal{M}$ is a TPPE if and only if it satisfies the PPE requirement with respect to $R'$ for every $R' = C(R)$. Let $\mathcal{M}^e$ denote the set of all such menus. Then, the
seller’s corresponding optimization program is given as follows:\(^{14}\)

\[
\max \left\{ (q_L, t_L), (q_H, t_H) \right\} \in M^e \quad p(t_L - c q_L) + (1 - p)(t_H - c q_H). \quad [P^e]
\]

4.2 Results

We begin our analysis of optimal TPPE menu by exploring a necessary condition for a screening menu to be a TPPE. Suppose that the firm offers \( R = \{b_L, b_H\} \) such that \( b_L \neq b_H \) intended to screen the high-type consumer. The problem is that the consumer may instead form, or deviate to, an alternative consumption plan from the offered bundles. In particular, choosing a constant bundle poses a potential benefit in terms of gain-loss utilities. Our first result provides the conditions for a screening menu to satisfy the PPE requirement with respect to the pooling menus. To state the result, define

\[
\alpha(p, \lambda) := \begin{cases} 
\frac{\lambda+1}{2} & \text{if } p < \frac{\lambda+2}{\lambda+3} \\
\frac{1+(1-p)(\lambda-1)}{1-(1-p)(\lambda-1)} & \text{if } p \geq \frac{\lambda+2}{\lambda+3}
\end{cases} \quad \text{and} \quad 
\beta(p, \lambda) := \begin{cases} 
\frac{1-p(\lambda-1)}{1+p(\lambda-1)} & \text{if } p \leq \frac{1}{\lambda+3} \\
\frac{2}{\lambda+1} & \text{if } p > \frac{1}{\lambda+3}.
\end{cases}
\]

(17)

Lemma 3. Fix any screening menu \( R = \{b_L, b_H\} \). Then, we obtain the following:

(a) \( R \) satisfies the PPE requirement with respect to \( R^H := \{b^H\} \) if and only if

\[
\frac{t_H - t_L}{v_H - v_L} \geq \theta_L \alpha(p, \lambda) \quad (\text{with the inequality being strict if } p < \frac{\lambda+2}{\lambda+3}); \quad (18)
\]

(b) \( R \) satisfies the PPE requirement with respect to \( R^L := \{b^L\} \) if and only if

\[
\frac{t_H - t_L}{v_H - v_L} \leq \theta_H \beta(p, \lambda) \quad (\text{with the inequality being strict if } p > \frac{1}{\lambda+3}). \quad (19)
\]

Furthermore, conditions (18) and (19) imply that \( R \) is a TPE.

Part (a) is derived from the following considerations. If \( b_H \) was so expensive relative to \( b_L \) as to satisfy (18), the consumer would not deviate to \( R^H \) (under which he would always consume \( b^H \)) for one of two reasons: either the low type prefers \( b_L \) to \( b_H \) so that \( R^H \) cannot be a PE, or the expected transfer from \( R^H \) is sufficiently higher than that from \( R \) such that

---

\(^{14}\)The fact that the (FIC) and (FIR) conditions are strict inequalities implies that the set of TPPE menus is not closed and hence not compact. This may cause non-existence of the optimal menu. To avoid this problem, we allow the (FIC) and (FIR) conditions to be satisfied as equality, in which case the optimum can only be attained approximately.
overall yields a lower ex ante payoff than $R$. Part (b) and condition (19) are derived similarly by considering $R^L$. These two conditions also turn out to ensure that the screening menu $R$ is itself a TPE, greatly facilitating our characterization below.

It follows from (18) and (19) that a screening TPPE menu exists only if the RHS of (19) is smaller than the RHS of (18), which delivers the necessary condition for the existence of a screening TPPE menu. We next show that this condition is also sufficient and holds if $\lambda$ is not too large. A reverse-screening TPPE menu can exist only if $\lambda$ is sufficiently large. In contrast, one can always find a pooling TPPE menu that yields a positive profit.

**Proposition 5.** Define $\bar{\lambda}_S \in (1, \infty)$ such that $\theta_L(\bar{\lambda}_S) = \theta_H(\bar{\lambda}_S)$. Also, define $\bar{\lambda}_R := \max \left\{ \frac{2\theta_H - (1+p)\theta_L}{(1-p)\theta_L}, 1 + \frac{1}{p} \right\} > \bar{\lambda}_S$. We obtain the following:

(a) There exists a screening TPPE menu if and only if $\lambda < \bar{\lambda}_S$. Also, there exist $p$ and $\bar{p}$ with $0 < p < \bar{p} < 1$ such that, as $p$ increases, $\bar{\lambda}_S$ is (continuously) decreasing for $p < \bar{p}$, constant for $p \in [p, \bar{p}]$, and increasing for $p > \bar{p}$.

(b) There exists a reverse-screening TPPE menu only if $\lambda \geq \bar{\lambda}_R$.

(c) There always exists a pooling TPPE menu that yields a positive profit.

An immediate implication from Proposition 5 is that only pooling menus can be sustained as TPPE if the loss aversion parameter is in the range $[\bar{\lambda}_S, \bar{\lambda}_R)$. Furthermore, part (a) shows that screening is feasible under a smallest range on $\lambda$ when $p$ takes an intermediate value: $\bar{\lambda}_S$ is minimized when $p \in [\bar{p}, \bar{p}]$.

To gain some intuition, note first that the gain-loss utilities are generated by the difference between the actual realized type and the expectation. Therefore, they occur more often when the type distribution has a greater variance, which, in the case of binary types, is true when $p$ is closer to a half. In contrast to the PE analysis earlier, we are now concerned with the consumer’s ex ante payoff comparisons across multiple PEs: a greater variance in the type distribution makes the contingent consumption plan less attractive ex ante.

It remains to show the shape of profit-maximizing TPPE menu. It turns out that a screening menu is optimal whenever it can be supported as a TPPE. We state our next theorem.

**Theorem 2.** The optimal menu that solves $[P^e]$ is

(a) a pooling menu if $\lambda \in [\bar{\lambda}_S, \bar{\lambda}_R)$;
(b) a screening menu if $\lambda < \bar{\lambda}_S$, and the optimal $q_L$ and $q_H$ solve
\[
\begin{align*}
\frac{c}{v'(q_L)} &= \frac{\theta_L \alpha(p, \lambda)}{p} - \frac{\theta_H (1 - p) \beta(p, \lambda)}{p} & (20) \\
\frac{c}{v'(q_H)} &= \theta_H \beta(p, \lambda). & (21)
\end{align*}
\]

Our proof of part (b) consists of two steps. First, we take a screening menu and solve a relaxed problem by imposing the PPE requirement only for a subset of deviations, $R^L$, $R^H$, and $R^{\emptyset H} = \{\emptyset, H\}$. As shown in Lemma 3, the deviations to $R^L$ and $R^H$ can be deterred by invoking (18) and (19). In order to deter the deviation to $R^{\emptyset H}$, the transfer for the low type, $t_L$, should not be too large since otherwise the buyer would find it better off ex ante to choose $R^{\emptyset H}$, i.e. $(U)$ is violated. This imposes another upper bound on $t_L$ in addition to the bound imposed by $(IR_L)$ as part of the TPE conditions. These two bounds can be written together as $t_L \leq \theta_L \alpha(p, \lambda)$ (where $\alpha(p, \lambda)$ is as defined in (17)). This constraint and (19) must be binding at the optimum of the relaxed problem, which leads to the first-order conditions given in (20) and (21). The second step of the proof then shows that the optimal menu for the relaxed problem satisfies all other PPE requirements.

We have not derived a boundary beyond which reverse-screening begins to dominate pooling, which can still be optimal when $\lambda \geq \bar{\lambda}_R$. Nonetheless, Theorem 2 demonstrates that the additional insurance motive captured by the PPE requirement favors pooling for a wide range of parameter values. We offer a numerical illustration in Figure 2. To highlight the contrast with the TPE results earlier, we set $\frac{\theta_H}{\theta_L} = 1.5$ as in Example 1 and plot $\bar{\lambda}_S$ and $\bar{\lambda}_R$ together with $\lambda_S$ and $\lambda_R$ appearing in Figure 1.

**Remark 1.** Notice the shaded region at the top left of Figure 2 where optimal TPE menu is pooling but screening is the optimal strategy under TPPE. The introduction of PPE requirements reduces profitability of both types of menu. For instance, optimal pooling TPE menu may entail an alternative PE in which the buyer never makes a purchase. When the likelihood of low type is large, the PPE requirements make a greater impact on pooling than on screening.

**Remark 2.** As previously mentioned, the revelation principle may fail under PPE, and hence, our restriction to direct menus is not without loss of generality. In Section S.3 of the Supple-
mentary Material, we find the possibility of a PPE menu that yields a higher expected profit for the seller than the optimal TPPE menu. Specifically, for some parameter values under which the optimal TPPE menu is pooling, the seller can improve profit by raising the price of the existing bundle in the optimal menu and by adding a redundant bundle with lower payment. The latter bundle is purchased by neither type in equilibrium, but is necessary to support the modified bundle to form a PPE: without it, another PE would arise to give a higher ex ante utility to the buyer.\footnote{In particular, the redundant bundle is used to eliminate the PE in which both types choose the null bundle.} Note that the PPE in this indirect menu remains pooling by both types on a single bundle. Redundant bundles may also be used to increase profitability of other types of (screening or reverse-screening) menus. But, it is unclear how the comparison of their (optimal) profits will be affected by such possibilities.
5 Extensions

5.1 A Continuum of Consumer Types

In this section, we explore the scope of our findings beyond binary consumer types by considering a continuum type case. Section S.4 of the Supplementary Material offers a detailed analysis, including formal proofs and numerical examples of the main results.

Suppose that \( \theta \in [\underline{\theta}, \bar{\theta}] \) with a cdf \( F \), which has a strictly positive and continuously differentiable pdf \( f \). Define the “virtual value” function as

\[
J(\theta) := \theta - \frac{1 - F(\theta)}{f(\theta)},
\]

and assume that it is strictly increasing. Without loss aversion, this assumption leads to full separation of type.

Let \((q, t) : [\underline{\theta}, \bar{\theta}] \to \mathbb{R}_+ \times \mathbb{R}\) denote a menu offered by the seller. For simplicity, we assume that \(q(\cdot)\) and \(t(\cdot)\) are continuous.\(^{18}\) We restrict attention to two classes of monotone menus:

(i) both \(q(\cdot)\) and \(t(\cdot)\) are non-decreasing; and
(ii) both \(q(\theta)\) and \(t(\theta)\) are non-increasing while \(\theta v(\theta)\) is non-decreasing. With some abuse of terminology, we refer to the former class of menus as screening menus and the latter as as reverse-screening menus.

We focus on TPE menus that satisfy the \((IC)\) and \((IR)\) constraints. Given a feasible TPE menu, let \(U(\theta'; \theta)\) denote the payoff of type \(\theta\) reporting \(\theta'\) and let \(U(\theta) := U(\theta; \theta)\). Then, the \((IC)\) constraint can be written as

\[
U(\theta) = \max_{\theta' \in [\underline{\theta}, \bar{\theta}]} U(\theta'; \theta), \forall \theta, \tag{22}
\]

while the \((IR)\) constraint as

\[
U(\theta) \geq \int_{\theta}^{\bar{\theta}} (t(s) - \lambda sv(q(s)))dF(s), \forall \theta. \tag{23}
\]

Taking the first-order condition from (22), we obtain

\[
t'(\theta) = \frac{\theta(v(q(\theta)))'(1 + F(\theta) + \lambda(1 - F(\theta)))}{1 + (1 - F(\theta)) + \lambda F(\theta)} = (v(q(\theta)))'G(\theta, \lambda), \tag{24}
\]

\(^{18}\)If the optimal schedule involves some jump(s), then it will manifest itself as a boundary solution of the optimization program since any such schedule can be approximated by a sequence of continuous schedules.
where

\[ G(\theta, \lambda) := \frac{\theta}{H(p, \lambda)} \quad \text{and} \quad H(p, \lambda) := \frac{1 + (1 - F(\theta)) + \lambda F(\theta)}{1 + F(\theta) + \lambda(1 - F(\theta))}. \]

Note that \( H(p, \lambda) \) is the continuum type counterpart of \( B(p, \lambda) \) in (11). It affects the rate at which the payment increases as the consumer’s type, and thus its corresponding quality, marginally increases. Without reference-dependent utility, the rate of increase is proportional to \( G(\theta, 1) = \theta \); this should be adjusted using \( H(p, \lambda) \) in the presence of reference-dependent utility. We refer to \( G(\theta, \lambda) \) as the “gain-loss adjusted type,” whose behavior is crucial for determining the optimal quality schedule. Note that \( G(\theta, \lambda) > \theta \) if \( \theta < F^{-1}\left(\frac{1}{2}\right) \) (and \( G(\theta, \lambda) < \theta \) if \( \theta > F^{-1}\left(\frac{1}{2}\right) \)), so the gain-loss adjusted type is leveled out. Moreover, \( H(\theta, \lambda) \) increases in \( \theta \) and does so faster with higher \( \lambda \), which may cause \( G(\theta, \lambda) = \frac{\theta}{H(\theta, \lambda)} \) to decrease.

The following assumption is sufficient to guarantee global incentive compatibility of the menu satisfying (24).

**Assumption 1.** \( \theta (1 + F(\theta) + \lambda (1 - F(\theta))) \) is non-decreasing in \( \theta \).

We next present our results in this section.

**Theorem 3.** Consider the case of a continuum of consumer types, and restrict attention to monotone menus. The optimal TPE menu has the following properties:

(a) Suppose that Assumption 1 holds and \( \frac{1}{\theta f(\theta)} > \frac{\lambda^2 + 2\lambda - 3}{2(\lambda + 1)} \). Then, pooling occurs around the highest type \( \bar{\theta} \).

(b) Suppose that \( \theta > 0, \theta f(\theta) > F(\theta) \forall \theta, \text{ and } f'(\theta) \leq 0 \forall \theta \). Then, there exists some \( \lambda > 1 \) such that, for any \( \lambda > \lambda \), pooling occurs over the entire interval \( [\theta, \bar{\theta}] \).

(c) Any reverse-screening menu is dominated by a pooling menu.

The inequality condition in part (a) above is equivalent to requiring that \( G_\theta(\bar{\theta}, \lambda) < 0 \), i.e. the gain-loss adjusted type decreases with the original type around the top. Without having to concern with information rent at the top, this means that the gain-loss adjusted virtual value also decreases, leading to pooling at the top. Note that the inequality in (a) never holds if \( \lambda = 1 \).

Part (b) gives a set of conditions sufficient for full pooling to be optimal. The first condition, \( \theta > 0 \), prevents the optimal menu from excluding the bottom type, as required.
by a full pooling menu. To understand the second condition, let us first note

$$\lim_{\lambda \to \infty} G(\theta, \lambda) = \theta \frac{1 - F(\theta)}{F(\theta)}.$$  

Thus, for sufficiently high \( \lambda \), the gain-loss adjusted type decreases going from \( \theta \) to \( \tilde{\theta} \) while it may not in-between. Then, the condition that \( \theta f(\theta) > F(\theta) \forall \theta \) ensures that this expression monotonically decreases over the entire interval so that \( G_\theta(\theta, \lambda) \) is always negative for sufficiently high \( \lambda \). The last condition, \( f'(\theta) \leq 0 \), ensures (along with the second condition) that \( G_{\theta \theta}(\theta) \leq 0 \) for sufficiently high \( \lambda \), which means worsening of the information rent problem due to loss aversion. Note that this condition is consistent with the observation in the previous binary type analysis that the screening effect adversely affects the profitability of a screening menu when the low type is abundant.

Part (c) shows that, in contrast to the binary type case, the reverse-screening menu can no longer be optimal with continuously many types. Recall that we consider reverse-screening menus whose quality/transfer schedule is non-increasing. Thus, the class of menus that are dominated by pooling menu here includes any menu in which the quality/transfer schedule is strictly decreasing over some local interval of types while being constant elsewhere. To understand this result, recall that a key feature of optimal reverse-screening with binary types was the participation effect: for the low willingness-to-pay consumer, the participation constraint must be binding at the optimum and therefore the additional loss arising from non-participation allows the firm to extract a greater payment from this type by offering a higher quality product (see (9)). With a continuum of types, this effect no longer applies. The participation constraint similarly binds for the lowest type but the corresponding revenue impact is only marginal. On the other hand, just as in the binary case, the incentive compatibility requirement works against the profitability of reverse-screening menus.

Remark 3. Our derivation of optimal menu is based on the restriction to monotone menus. Therefore, Theorem 3 implies the following: when the conditions stipulated in part (a) or (b) are met, the optimal TPE menu involves either pooling, or else, strict violation of monotonicity (“local reverse-screening”). Neither contractual form is predicted by the standard model with increasing virtual value.
5.2 Ex Ante Participation

The optimal menus described in our analysis above have the feature that the buyer’s ex ante expected utility (including anticipated gain-loss) often falls below zero. This can be problematic for the seller if the consumer can calculate the ex ante loss and find some commitment device to stay away from the menu altogether. In our previous working paper (2012), we showed that introducing an additional ex ante participation constraint to the analysis (requiring the buyer’s ex ante expected utility to be non-negative) does not alter our central message. In fact, the loss averse consumer’s ex ante insurance motives can induce the profit-maximizing firm to offer pooling menus under a wider range of parameters.

The same conclusion also holds in an alternative model of ex ante contracting where the buyer’s participation decision is made before his type is realized. That is, the buyer, when deciding whether to accept the menu offered by the seller, is uncertain about his willingness to pay. Analyzing the optimal PPE menu in this alternative model reveals that the pooling menu is optimal for a larger set of parameters under the ex ante participation constraint than under the ex post one. Again, the buyer’s insurance motives reinforce the benefits of pooling.\footnote{This ex ante participation model is fully analyzed in a separate work, which can be provided upon request. Herweg and Mierendorff (2013) study an alternative ex ante participation model of price discrimination.} These additional results demonstrate that the optimality of pooling is a general phenomenon with loss averse consumers, valid under different decision-making scenarios and timelines.

5.3 Alternative Consumption Preference

Our main analysis above considered the case where consumer preferences are vertically differentiated for quality. We next examine an alternative utility structure where two types of consumers have the standard Hotelling preferences over horizontally differentiated goods. A type-\(\theta\) consumer’s intrinsic utility is given by

\[
m(b; \theta) := \bar{s} - (\theta - q)^2 - t
\]

for a bundle \(b = (q, t)\), where \(q \in [0, 1]\) denotes the product position. We assume that \(\theta\) takes binary values, \(\theta_L = 0\) and \(\theta_H = 1\) with probabilities \(p\) and \(1 - p\), respectively. Note that \(\theta\) denotes each type’s bliss point. We assume the same constant marginal production cost.
for any product, which is normalized to zero, and also assume that $\overline{s} > 1$, which guarantees that both types of consumers gain a positive gross surplus for any $q \in [0, 1]$.

It can be easily shown that without gain-loss utilities the seller would maximize profits by offering the screening menu $R^m = \{b_L, b_H\} = \{(0, \overline{s}), (1, \overline{s})\}$ with maximal differentiation, and he fully extracts consumer surplus. Note that with $b_L = (0, \overline{s})$ and $b_H = (1, \overline{s})$ the incentive constraints are non-binding for both types and the seller optimally sets the prices at which the two participation constraints are binding.

In Section S.5 of the Supplementary Material, we show that, with horizontally differentiated preferences, reference-dependence and loss aversion do not limit the benefits of screening. The optimal TPE menu is similar to $R^m$ with maximal product differentiation and equal to $\{b_L, b_H\} = \{(0, \frac{1+\lambda}{2} \overline{s}), (1, \frac{1+\lambda}{2} \overline{s})\}$ for all values of $p$ and $\lambda$. We also show that in this alternative model a screening PPE menu exists for all $p$ and $\lambda$ unlike in the vertical differentiation model where a screening PPE menu fails to exist with sufficiently large $\lambda$. With the symmetric Hotelling preferences, consumers do not actually experience any gain or loss from choosing their targeted bundles since the reference points of the two types are essentially identical.

### 5.4 Alternative Reference Point

An important motivation for adopting the KR model of reference-dependent preferences arose from recognizing the role of expectations. While in the KR model the reference point is stochastic and equals the distribution of expected outcomes, the models of disappointment aversion (Bell (1985), Loomes and Sugden (1986)) formulate the reference point as the expected utility certainty equivalent of a gamble. A similar approach in our price discrimination setup would be to take the expected utility of the contingent bundles as reference point.\(^{20}\)

Formally, with binary types and menu $\{b_L, b_H\}$, consider type-$\theta$ buyer’s gain-loss utility from bundle $b = (q, t)$ to be

$$\mu \left[ \theta v(q) - (p\theta_L v(q_L) + (1 - p)\theta_H v(q_H)) \right] + \mu \left[ (p t_L + (1 - p) t_H) - t \right], \quad (25)$$

where $\mu$ is the loss aversion indicator function as defined in (1).

\(^{20}\)Orhun (2009) considers a similar model. De Meza and Webb (2007) apply the disappointment aversion model to an incentive provision setup.
In Section S.6 of the Supplementary Material, we solve for the optimal menu under this alternative specification of reference-dependent preferences. It turns out that this analysis is very close to that of optimal TPE menus in Section 3. Whenever a pooling menu maximizes the firm’s profit under TPE, it does so here as well.

6 Conclusion

We often find sellers offering menus with just a small number of bundles. This paper demonstrates that such observations are consistent with profit-maximizing firms that face loss-averse consumers. We show that, in the binary-type case, a pooling menu is the seller’s optimal menu under a range of loss aversion parameter if the low willingness-to-pay consumers are sufficiently abundant. This result arises as a consequence of the interplay between loss aversion and asymmetric information. The benefits from screening with multiple bundles become even more restricted when the consumer is capable of choosing the personal equilibrium that generates the highest ex ante payoff. We also identify conditions under which partial or even full pooling dominates screening for the seller facing a continuum of consumer types.

Our theory offers explanations for why some sellers fail to fully materialize the benefits from further price discrimination in industries that seem to have low fixed costs of adding another product variant. Moreover, it can complement the existing theories of coarse screening. Besides menu costs, limited benefits from adding more product variants could also be due to computational reasons (e.g. Wilson (1993)) and other behavioral biases (e.g. Iyengar and Lepper (2000)).

While we take the uncertainty to affect willingness to pay directly, variations in willingness to pay may arise from other sources, for example, income shocks. In such a case, however, the buyer should also realize gain-loss utility in that uncertain monetary dimension. Also, our model suggests that reverse-screening can be optimal if the consumer is significantly loss-averse (at least with only few consumer types), but this is difficult to justify in practice. Measuring the degree of consumer loss aversion in price discrimination settings with utilities derived from quality consumption as well as money may shed insights into this dichotomy.
APPENDIX

A Omitted Proofs from Section 3

In the proofs throughout the Appendix, we simplify notation by letting \( v_L := v(q_L) \) and \( v_H := v(q_H) \), and refer to their derivatives as \( v'_L \) and \( v'_H \), respectively.

Proof of Lemma 1: The proof consists of two claims.

Claim 1. If the optimal menu satisfies \( \theta_Lv_H \geq \theta_Lv_L \), then it must be that \( t_H \geq t_L \).

Proof. Suppose to the contrary that \( t_L > t_H \). Clearly, we must have both \((IR)\) constraints binding or

\[
\begin{align*}
    u(\emptyset|\theta_H, R) &= u(r_L|\theta_L, R) = \theta_Lv_L - t_L - (1 - p)\lambda[\theta_Hv_H - \theta_Lv_L + t_L - t_H] \quad \text{(A1)} \\
    u(\emptyset|\theta_L, R) &= u(r_H|\theta_H, R) = \theta_Hv_H - t_H + p[\theta_Hv_H - \theta_Lv_L + t_L - t_H]. \quad \text{(A2)}
\end{align*}
\]

Since \( u(\emptyset|\theta_H, R) = u(\emptyset|\theta_L, R) \), equating (A1) and (A2) yields

\[
[1 + p + (1 - p)\lambda](t_L - t_H) = [1 + p + (1 - p)\lambda](\theta_Lv_L - \theta_Hv_H),
\]

which is a contradiction since \( t_L - t_H > 0 \) but \( \theta_Lv_L - \theta_Hv_H \leq 0 \).

Claim 2. It is never optimal to offer a menu with \( \theta_Lv(q_L) > \theta_Hv(q_H) \).

Proof. Suppose that \( \theta_Lv(q_L) > \theta_Hv(q_H) \). A similar argument to that in the proof of Claim 1 can be used to show \( t_L \geq t_H \). Then, re-write \((IR)\) constraints as

\[
t_H \leq \theta_H \frac{\lambda + 1}{2} + v_H \quad \text{and} \quad t_L \leq t_H + \frac{\theta_Lv_L - \theta_Hv_H}{B(p, \lambda)}.
\]

Since both constraints must clearly be binding, we can substitute these into the objective function and take the first-order conditions (FOCs) as follows:

\[
\frac{c}{v'_L} = \frac{\theta_L}{B(p, \lambda)} \quad \text{and} \quad \frac{c}{v'_H} = \frac{[(\lambda + 1)B(p, \lambda) - 2p] \theta_H}{2(1 - p)B(p, \lambda)}.
\]

This, however, yields a contradiction since

\[
\frac{c}{v'_H} - \frac{c}{v'_L} = \frac{(\lambda + 1)B(p, \lambda)\theta_H - 2[p\theta_H + (1 - p)\theta_L]}{2(1 - p)B(p, \lambda)} \geq \frac{[(\lambda + 1)B(p, \lambda) - 2 \theta_H]}{2(1 - p)B(p, \lambda)} \geq 0,
\]

\]
where the last inequality holds since \((\lambda + 1)B(p, \lambda) \geq (\lambda + 1)B(0, \lambda) = 2, \forall \lambda, p. \) □

**Proof of Proposition 3.** Consider maximizing profit under the \((IC)\) and \((IR)\) constraints and under the quality constraint, \(q_H - q_L \geq 0.\) We show the following: When the quality constraint is not binding, the optimal qualities must be given by \((12)\) and \((13)\), and the quality constraint is binding if \((14)\) holds.

First, one can easily check that \((IR)_{H}\) is implied by \((IR)_{L}\) and \((IC)_{H}\) since
\[
 u(\theta_H | \theta_H, R) \geq u(r_L | \theta_H, R) \geq u(r_L | \theta_L, R) \geq u(\emptyset | \theta_L, R) = u(\emptyset | \theta_H, R),
\]
(A3)
where the second inequality holds since if two types choose the same bundle, \(r_L\), then \(\theta_H\) is better off in terms of both intrinsic and gain-loss utilities. Next, after rearrangement, we can write \((IR)_{L}\) and \((IC)_{H}\) constraints respectively as
\[
\begin{align*}
t_L \leq & \theta_L \frac{\lambda + 1}{2} v_L \\ \frac{\theta_L}{B(p, \lambda)} \leq & \frac{t_H - t_L}{v_H - v_L} \leq \frac{\theta_H}{B(p, \lambda)},
\end{align*}
\]
(A4) (A5)
where \(B(p, \lambda) = \frac{1 + (1 - p) + p^{2}}{1 + p + (1 - p)\lambda}\) as defined in \((4)\). \(^{21}\) By the usual argument, \((IR)_{L}\) and \((IC)_{H}\) must be binding.

Using the two binding constraints, we obtain \((9)\) and \((11)\) for \(t_L\) and \(t_H\), respectively. Substituting these into the objective function, the seller’s problem becomes
\[
\begin{align*}
\max_{(q_L, q_H)} \quad & p(t_L - cq_L) + (1 - p)(t_H - cq_H) \\
= & \frac{\lambda + 1}{2} t_L v_L + (1 - p) \frac{\theta_H (v_H - v_L)}{B(p, \lambda)} - pcq_L - (1 - p)cq_H,
\end{align*}
\]
subject to \(q_H \geq q_L\). Ignoring the quality constraint for the moment, the FOCs with respect to \(q_L\) and \(q_H\) yield \((12)\) and \((13)\). One can then check that the RHS of \((13)\) is no larger than that of \((12)\) if and only if the inequality \((14)\) holds, which means that the quality constraint is binding in such a case.

To obtain the comparative statics for \(q_L\), \(q_H\), and \(\lambda_S\), let us first observe the following facts: (i) \(B(p, \lambda)\) increases with \(\lambda > 1\) if and only if \(p > \frac{1}{2};\) (ii) \(B(p, \lambda)\) increases with \(p\) if \(\lambda > 1;\) and (iii) \((\lambda + 1)B(p, \lambda)\) increases from 1 to infinity as \(\lambda\) increases starting from \(\lambda = 1.\)

\(^{21}\)The full expression of these constraints are given in Section S.1 of the Supplementary Material.
The comparative statics for $q_H$ directly follows from (i) and the fact that $\frac{\partial}{\partial \frac{c}{v}}$ is increasing. As for the comparative statics regarding $q_L$, rewrite the maximand in (12) as

$$\frac{\theta_L - [2(1 - p)\theta_H] / [(\lambda + 1)B(p, \lambda)]}{2p/\lambda + 1},$$

whose numerator increases in $\lambda$ by (iii), while its denominator decreases. So the optimal $q_L$, if not 0, must increase. The existence and properties of $\lambda_S$ follow from (ii) and (iii).

Before proving Lemma 2 and Proposition 4, we write here the $(IC)$ and $(IR)$ constraints for the reverse-screening menu, whose forms differ depending on whether $\theta_L v_L \geq \theta_H v_H$ or $\theta_L v_L \leq \theta_H v_H$.\(^{22}\)

In case $\theta_L v_L \geq \theta_H v_H$, the constraints $(IC_H)$, $(IC_L)$, $(IR_H)$, and $(IR_L)$ are respectively given as

$$t_L - t_H \geq \frac{[1 + (1 - p)p\lambda] \theta_H (v_L - v_H) - p(\lambda - 1)(\theta_H - \theta_L)v_L}{1 + p + (1 - p)p\lambda} \tag{A6}$$

$$\frac{[1 + (1 - p)p\lambda] \theta_H (v_L - v_H) + (1 - p)(\lambda - 1)(\theta_H - \theta_L)v_H}{1 + p + (1 - p)p\lambda} \geq t_L - t_H \tag{A7}$$

$$\theta_H (\lambda + 1)v_H \geq 2t_H \tag{A8}$$

$$[1 + (1 - p)p\lambda] \theta_L v_L + (1 - p)(\lambda - 1)\theta_H v_H \geq [1 + p + (1 - p)p\lambda] t_L - (1 - p)(\lambda - 1)t_H \tag{A9}$$

while in case $\theta_L v_L \leq \theta_H v_H$, they are given as

$$[1 + p + (1 - p)p\lambda] (t_L - t_H) \geq 2\theta_H (v_L - v_H) \tag{A10}$$

$$(\lambda + 1)\theta_L (v_L - v_H) \geq [1 + p + (1 - p)p\lambda] (t_L - t_H) \tag{A11}$$

$$[1 + p + (1 - p)p\lambda] \theta_H v_H + p(\lambda - 1)\theta_L v_L \geq 2t_H \tag{A12}$$

$$(\lambda + 1)\theta_L v_L \geq [1 + p + (1 - p)p\lambda] t_L - (1 - p)(\lambda - 1)t_H. \tag{A13}$$

**Proof of Lemma 2:** To prove (a), let us consider both cases of reverse-screening menu. In case $\theta_L v_L \leq \theta_H v_H$, the LHS of (A11) being greater than the RHS of (A10) yields (15) after rearrangement. In case $\theta_L v_L \geq \theta_H v_H$, combining (A7) and (A6) yields

$$(\lambda + 1)v_H - 2v_L \geq 0, \tag{A14}$$

\(^{22}\)For the full expressions, see Section S.1 of the Supplementary Material.
which implies \( \frac{\lambda+1}{2} \geq \frac{v_L}{v_H} \geq \frac{\theta_H}{\theta_L} \).

To prove (b), consider maximizing profit under the constraints (A6) to (A9) and the constraint that \( \theta_L v_L - \theta_H v_H \geq 0 \). It suffices to show that the last constraint must be binding. First, the same inequalities as in (A3) can be used to show that (A8) is implied by (A6) and (A9). Next, to identify the binding constraints, we depict as a shaded area in Figure 3 below the set of \((t_L, t_H)\)'s satisfying (A6), (A7), and (A9) for any given \(q_L\) and \(q_H\). Clearly, \((IC_H)\) and \((IR_L)\), i.e. (A6) and (A9), must be binding.\(^{23}\)

\[ t_H(q_L, q_H) = \frac{(\lambda + 1)\theta_H v_H}{2} - 2(\theta_H - \theta_L)v_L \]
\[ t_L(q_L, q_H) = \frac{[1 + (1 - p) + p\lambda]\theta_H (v_L - v_H) - p(\lambda - 1)(\theta_H - \theta_L)v_L}{1 + p + (1 - p)\lambda} + t_H(q_L, q_H). \]

Combining the two binding constraints, we obtain

Note that given (A6) is binding, (A7) is satisfied if and only if (A14) is satisfied so we can replace (A7) by (A14). Now, using (A14) and \( \theta_L v_L - \theta_H v_H \geq 0 \) as constraints, the Lagrangian for the maximization problem can be written as

\[ \mathcal{L}(q_L, q_H, \mu, \eta) = p(t_L(q_L, q_H) - c q_L) + (1 - p)(t_H(q_L, q_H) - c q_H) + \mu [(\lambda + 1)v_H - 2v_L] + \eta(\theta_L v_L - \theta_H v_H). \]

\(^{23}\)A formal proof is a straightforward translation of graphical illustration and is thus omitted.
where $\mu$ and $\eta$ are nonnegative multipliers. Suppose that $\theta_L v_L - \theta_H v_H \geq 0$ is not binding so $\eta = 0$. Substituting (A15) and (A16) into (A17), the FOCs are given by

$$\frac{c}{v'_L} + \frac{2\mu}{p} = \frac{[1 + p - p^2 + (1 - p + p^2)\lambda]\theta_L - (1 - p)(\lambda + 1)\theta_H}{p[1 + p + (1 - p)\lambda]} =: \Psi_L \tag{A18}$$

$$\frac{c}{v'_H} - \frac{\mu(\lambda + 1)}{1 - p} = \frac{[1 - 2p + 2(1 + p)\lambda + \lambda^2]\theta_H}{2[1 + p + (1 - p)\lambda]} =: \Psi_H. \tag{A19}$$

One can verify that $\Psi_H > \Psi_L$. Given this, and $\mu \geq 0$, (A18) and (A19) require $q_H > q_L$, which is a contradiction.

**Proof of Proposition 4:** By Lemma 2, we focus on the case $\theta_H v_H - \theta_L v_L \geq 0$. Consider maximizing profit under the constraints (A10) to (A13), and $\theta_H v_H - \theta_L v_L \geq 0$, also subject to $q_L \geq q_H$. We show that $q_L = q_H$ if (16) holds.

First, we can ignore (A12) since it is implied by (A10) and (A13) for the same reason as in (A3). To identify the binding constraints, with $q_L$ and $q_H$ fixed, we depict the set of $(t_L, t_H)$ satisfying the constraints, (A10), (A11), and (A13), to obtain the same graph as Figure 3. From this, it is immediate that (A13) and (A10) are binding, which gives us

$$t_H(q_L, q_H) = \frac{(\lambda + 1)\theta_L v_L}{2} - \theta_H(v_L - v_H)$$

$$t_L(q_L, q_H) = \frac{(\lambda + 1)\theta_L v_L}{2} - \theta_H \frac{(1 - p)(\lambda - 1)}{1 + p + (1 - p)\lambda}(v_L - v_H).$$

Ignoring the constraint $q_L \geq q_H$ for the moment, we set up the Lagrangian

$$\mathcal{L}(q_L, q_H, \mu, \eta) = p(t_L(q_L, q_H) - c q_L) + (1 - p)(t_H(q_L, q_H) - c q_H)$$

$$+ \mu((\lambda + 1)v_H - 2v_L) + \eta(\theta_H v_H - \theta_L v_L).$$

whose FOCs are

$$\frac{c}{v'(q_L)} + \frac{2\mu + \eta \theta_L}{p} = \frac{[1 + p + (1 - p)\lambda](\lambda + 1)\theta_L - 2(1 - p)(\lambda + 1)\theta_H}{2p[1 + p + (1 - p)\lambda]} =: \tilde{\Psi}_L \tag{A20}$$

$$\frac{c}{v'(q_H)} - \frac{\mu(\lambda + 1) + \eta \theta_H}{1 - p} = \frac{(\lambda + 1)\theta_H}{1 + p + (1 - p)\lambda} =: \tilde{\Psi}_H. \tag{A21}$$

One can check that $\tilde{\Psi}_H \geq \tilde{\Psi}_L$ if (16) holds, which implies that given $\mu, \eta \geq 0$, (A20) and (A21) can only be satisfied when $q_H \geq q_L$. Thus, $q_L = q_H$ if (16) holds.
Now rewrite (16) as
\[ \lambda \leq \frac{1}{1-p} \left( \frac{2\theta_H}{\theta_L} - (1+p) \right) =: \lambda_R. \]

It is straightforward to check that \( \lambda_R \) increases with both \( p \) and \( \frac{\theta_H}{\theta_L} \). This completes the proof of Proposition 4. \( \square \)

**B Omitted Proofs from Section 4**

**Proof of Lemma 3.** Part (a): Consider any screening menu \( R \) and a deviation \( R' = RH \), for which \((FIC_L), (FIR_L), (FIC_H), (FIR_H), \) and \((U)\) can be written as

\[ \frac{t_H - t_L}{v_H - v_L} > \theta_L \frac{\lambda + 1}{2} \]  
\[ t_H > \theta_L \frac{\lambda + 1}{2} v_H \]  
\[ \frac{t_H - t_L}{v_H - v_L} > \theta_H \frac{1 + p + (1 - p)\lambda}{2} + \frac{p(\lambda - 1)}{2} \left( \frac{\theta_L v_H - \theta_H v_L}{v_H - v_L} \right) 1_{\{\theta_L v_H - \theta_H v_L \geq 0\}} \]  
\[ t_H > \frac{1}{2} \left( \theta_H (1 + p + (1 - p)\lambda) + p(\lambda - 1)\theta_L \right) v_H \]  
\[ \frac{t_H - t_L}{v_H - v_L} \geq \theta_L \frac{1 + (1 - p)(\lambda - 1)}{1 - (1 - p)(\lambda - 1)} > 0. \]  

Note first that (A24) contradicts \((IC_H)\) in \((A5)\) since the RHS of \((A24)\) is greater than \( \frac{\theta_H}{\theta_{L[p,\lambda]}} \). It is straightforward to check that the RHS of \((A25)\) is greater than the RHS of \((A23)\), so \((A25)\) implies \((A23)\). Also, subtracting the \((IR_L)\) constraint, \( t_L \leq \theta_L \frac{\lambda + 1}{2} v_L \), from \((A23)\) and rearranging yields \((A22)\). Thus, the PPE requirement with respect to \( RH \) boils down to satisfying either \((A22)\) or \((A26)\), which gives us the condition in \((18)\).

Part (b): Let us next consider a deviation \( R' = RL \), for which \((FIC_L), (FIR_L), (FIC_H), (FIR_H), \) and \((U)\) can be written as

\[ \frac{t_H - t_L}{v_H - v_L} < \theta_L \frac{1 + p + (1 - p)\lambda}{\lambda + 1} - \frac{(\lambda - 1)(1-p)}{\lambda + 1} \left( \frac{\theta_L v_H - \theta_H v_L}{v_H - v_L} \right) 1_{\{\theta_L v_H - \theta_H v_L \geq 0\}} \]  
\[ \frac{t_L}{v_L} > \theta_L \frac{\lambda + 1}{2} \]  
\[ \frac{t_H - t_L}{v_H - v_L} < \theta_H \frac{2}{\lambda + 1} \]  
\[ \frac{t_L}{v_L} > \frac{1}{2} \left( \theta_H (1 + p + (1 - p)\lambda) + p(\lambda - 1)\theta_L \right) \]  

35
\[
\frac{t_H - t_L}{v_H - v_L} \leq \theta_H \frac{1 - p(\lambda - 1)}{1 + p(\lambda - 1)}.
\]  

(A31)

Note first that (A27) contradicts (IC_L) in (A5) since the RHS of (A27) is smaller than \( \frac{\theta_L}{B(p, \lambda)} \). It is straightforward to check that (A28) and (A30) contradict (IR_L) in (A4), so they can be ignored. Thus, the PPE requirement with respect to \( R^L \) boils down to satisfying either (A29) or (A31), which gives us the condition in (19).

The statement that (IC_L) are (IC_H) are implied by (18) and (19) can be established if we show that for any \( p \in (0, 1) \) and \( \lambda > 1 \),

\[
\alpha(p, \lambda) \geq \frac{1}{B(p, \lambda)} \geq \beta(p, \lambda).
\]

(A32)

To do so, observe first that \( \frac{\lambda + 2}{\lambda + 3} > \frac{1}{B(p, \lambda)} = \frac{1 + p + (1 - p)\lambda}{1 + (1 - p) + p\lambda} > \frac{2}{\lambda + 1} \). Given this, (A32) will be shown if (i) \( \frac{1 + p + (1 - p)\lambda}{1 + (1 - p) + p\lambda} \geq \frac{\lambda + 2}{\lambda + 3} \) when \( p \geq \frac{\lambda + 2}{\lambda + 3} \) and (ii) \( \frac{1 - p(\lambda - 1)}{1 + (1 - p) + p\lambda} \leq \frac{1 + p + (1 - p)\lambda}{1 + (1 - p) + p\lambda} \) when \( p \leq \frac{1}{\lambda + 3} \).

To prove this, observe that if \( p \geq \frac{\lambda + 2}{\lambda + 3} \), then

\[
1 + (1 - p)(\lambda - 1) - \frac{1 + p + (1 - p)\lambda}{1 + (1 - p) + p\lambda} = \frac{(\lambda - 1)(\lambda + 2 - p(\lambda + 1))}{(1 - (1 - p)(\lambda - 1))(1 + (1 - p) + p\lambda)} > 0,
\]

and also that

\[
\frac{1 + p + (1 - p)\lambda}{1 + (1 - p) + p\lambda} - \frac{1 - p(\lambda - 1)}{1 + p(\lambda - 1)} = \frac{(\lambda - 1)(1 + p + p\lambda)}{(1 + (1 - p) + p\lambda)(1 + p(\lambda - 1))} > 0,
\]

as desired. \(\square\)

**Proof of Proposition 5**

**Part (a):** We prove the if part in the proof of Theorem 2 by constructing a screening PPE menu that is optimal among all PPE menus under the given condition. Here we only prove the only if part. To do so, note that we can combine (18) and (19) in Lemma 3 to write the following necessary condition for any screening menu \( R \) to be a PPE:

\[
\theta_L \alpha(p, \lambda) \leq \frac{t_H - t_L}{v_H - v_L} \leq \theta_H \beta(p, \lambda)
\]

(A33)

with the first inequality being strict if \( p < \frac{\lambda + 2}{\lambda + 3} \) and the second inequality being strict if \( p > \frac{1}{\lambda + 3} \). This condition can hold only if the RHS of (A33) is greater than the LHS, that is,
\[ \frac{\theta_H}{\theta_L} > \frac{\alpha(p, \lambda)}{\beta(p, \lambda)} =: \gamma(p, \lambda). \] The following claim establishes several properties of \( \gamma \).

**Claim 3.** \( \gamma \) is a continuous function that satisfies the following properties:

(i) \( \gamma(p, \cdot) \) is strictly increasing;

(ii) \( \gamma(p, 1) = 1 \) and \( \lim_{\lambda \to \infty} \gamma(p, \lambda) = \infty \); and

(iii) \( \gamma(\cdot, \lambda) \) is strictly increasing if \( p < \frac{1}{\lambda + 3} \), constant if \( p \in \left[ \frac{1}{\lambda + 2}, \frac{\lambda + 2}{\lambda + 3} \right] \), and strictly decreasing if \( p > \frac{\lambda + 2}{\lambda + 3} \).

**Proof.** Clearly, \( \gamma \) is continuous. It is also clear that \( \alpha(p, \cdot) \) is strictly increasing and \( \beta(p, \cdot) \) is strictly decreasing; thus, \( \gamma(p, \cdot) \) is strictly increasing, proving (i). To prove (ii), note that \( \alpha(p, 1) = \beta(p, 1) = 1 \) so \( \gamma(p, 1) = 1 \). Also, for sufficiently large \( \lambda \), \( \alpha(p, \lambda) = \frac{\lambda + 1}{2} \) and \( \beta(p, \lambda) = \frac{2}{\lambda + 1} \), so \( \lim_{\lambda \to \infty} \gamma(p, \lambda) = \lim_{\lambda \to \infty} \frac{(\lambda + 1)^2}{4} = \infty \). Part (iii) follows from combining that \( \gamma(p, \lambda) = \frac{\alpha(p, \lambda)}{\beta(p, \lambda)} \) and the fact that \( \alpha(\cdot, \lambda) \) is strictly decreasing if \( p > \frac{\lambda + 2}{\lambda + 3} \) and constant otherwise while \( \beta(\cdot, \lambda) \) is strictly decreasing if \( p < \frac{1}{\lambda + 3} \) and constant otherwise.

Properties (i) and (ii) along with the continuity of \( \gamma \) imply that there exists \( \overline{\lambda}_S > 1 \) such that \( \frac{\theta_H}{\theta_L} > \gamma(p, \lambda) \) if and only if \( \lambda < \overline{\lambda}_S \).

Next observe that by (iii), we have \( \max_{p \in [0, 1]} \gamma(p, \lambda) = \frac{(\lambda + 1)^2}{4} = \gamma(p, \lambda) \) for any \( p \in \left[ \frac{1}{\lambda + 3}, \frac{\lambda + 2}{\lambda + 3} \right] \). Letting \( \lambda = 2\sqrt{\frac{\theta_H}{\theta_L} - 1} \), we solve \( \frac{(\lambda + 1)^2}{4} = \frac{\theta_H}{\theta_L} \) to obtain \( \lambda = \overline{\lambda} \). Thus, letting \( p = \frac{1}{\lambda + 3} \) and \( \overline{p} = \frac{\lambda + 2}{\lambda + 3} \), we have \( \overline{\lambda}_S = \overline{\lambda} \) for \( p \in [p, \overline{p}] \). The fact that \( \gamma(\cdot, \lambda) \) is increasing in \( p \) if \( p \in (0, \frac{1}{\lambda + 3}) \) and \( \gamma \) is increasing in \( \lambda \), means that \( \overline{\lambda}_S \) is decreasing in \( p \) and greater than \( \overline{\lambda} \) for \( p \in (0, \frac{1}{\lambda + 3}) \). Similarly, \( \overline{\lambda}_S \) is decreasing in \( p \) and greater than \( \overline{\lambda} \) in the range \( (\frac{\lambda + 2}{\lambda + 3}, 1) \). Also, the monotonicity of \( \overline{\lambda}_S \) implies that \( \overline{\lambda}_S \) is maximized at \( p = 0 \) or 1. Since \( \gamma(0, \lambda) = \gamma(1, \lambda) = \frac{\lambda + 1}{2} \), solving \( \frac{\lambda + 1}{2} = \frac{\theta_H}{\theta_L} \) yields \( \lambda = \frac{2\theta_H}{\theta_L} - 1 \). Thus, if we let \( \overline{\lambda} = \frac{2\theta_H}{\theta_L} - 1 \), then \( \overline{\lambda}_S < \overline{\lambda} \) for all \( p \in (0, 1) \).

**Part (b):** Consider any reverse-screening menu satisfying \( \theta_H v_H \geq \theta_L v_L \). (We will later discuss reverse-screening menu with \( \theta_H v_H < \theta_L v_L \)). To facilitate the reference, we rewrite here \( (IC_H) \) and \( (IC_L) \) constraints in (A10) and (A11) as

\[
\frac{2\theta_H}{1 + p + (1 - p)\lambda} \leq \frac{t_L - t_H}{(IC_H)} v_L - v_H \leq \frac{(\lambda + 1)\theta_L}{1 + p + (1 - p)\lambda}. \tag{A34}
\]
Let us first consider a deviation $R' = R^L = \{b_L\}$. The conditions $(FIC_L)$, $(FIR_L)$, $(FIC_H)$, $(FIR_H)$, and $(U)$ are given as

\[
\frac{t_L - t_H}{v_L - v_H} > \theta_L \frac{\lambda + 1}{2} \tag{A35}
\]

\[
\frac{t_L}{v_L} > \theta_L \frac{\lambda + 1}{2} \tag{A36}
\]

\[
\frac{t_L - t_H}{v_L - v_H} > \theta_H \frac{1 + p + (1 - p)\lambda}{2} \tag{A37}
\]

\[
\frac{t_L}{v_L} > \frac{1}{2} [\theta_H (1 + p + (1 - p)\lambda) + p(\lambda - 1)\theta_L] \tag{A38}
\]

\[
t_L - t_H \begin{cases} 
\geq \theta_H & \text{if } p(\lambda - 1) < 1 \\
\leq \theta_H & \text{if } p(\lambda - 1) > 1,
\end{cases} \tag{A39}
\]

respectively. In addition, $(U)$ always holds if $p(\lambda - 1) = 1$. Note first that (A35) contradicts $(IC_L)$ in (A34). We can also ignore (A38) because it implies (A36). However, (A36) contradicts $(IR_L)$ in (A13) since $(1 + p + (1 - p)\lambda)t_L - (1 - p)(\lambda - 1)t_H > 2t_L$. Thus, the reverse-screening menu $R$ must satisfy either (A37) or (A39). Since $\frac{1+p+(1-p)\lambda}{2} > 1$, (A37) implies (A39) in case $p(\lambda - 1) < 1$, which means that (A39) must hold if $p(\lambda - 1) < 1$. If $p(\lambda - 1) > 1$, then either (A37) or (A39) must hold.

Consider next a deviation $R' = R^H = \{b_H\}$. Then, the conditions $(FIC_L)$, $(FIR_L)$, $(FIC_H)$, $(FIR_H)$, and $(U)$ are given as

\[
\frac{t_L - t_H}{v_L - v_H} < \theta_L \frac{1 + p + (1 - p)\lambda}{\lambda + 1} \tag{A40}
\]

\[
\frac{t_H}{v_H} > \theta_L \frac{\lambda + 1}{2} \tag{A41}
\]

\[
\frac{t_L - t_H}{v_L - v_H} < \theta_H \frac{2}{\lambda + 1} \tag{A42}
\]

\[
\frac{t_H}{v_H} > \frac{1}{2} [\theta_H (1 + p + (1 - p)\lambda) + p(\lambda - 1)\theta_L] \tag{A43}
\]

\[
t_L - t_H \leq \theta_L, \tag{A44}
\]

respectively. First, each of (A40) and (A42) implies (A44) since the right-hand sides of the former inequalities are both smaller than the RHS of the latter. So, (A40) and (A42) can be ignored. Similarly, (A43) implies (A41) and can thus be ignored. In sum, either (A41) or (A44) must hold for the buyer not to deviate to $R^H$. 

Claim 4. If either \( p(\lambda - 1) < 1 \) or \( p(\lambda - 1) \geq 1 \) and \( p \geq \frac{\theta_L}{2\theta_H - \theta_L} \), then (A41) cannot be satisfied by any reverse-screening PPE menu.

Proof. Suppose that under the assumed conditions, there is a reverse-screening PPE menu that satisfies (A41). We first obverse that (A10) and (A41) together imply

\[
\frac{t_L}{v_L} > \frac{2\theta_H}{1 + p + (1 - p)\lambda}.
\]  

(A45)

To see it, rewrite (A10) and (A41) as

\[
t_L - t_H \geq \left( \frac{2\theta_H}{1 + p + (1 - p)\lambda} \right) (v_L - v_H) \]

\[
t_H > \theta_L \left( \frac{\lambda + 1}{2} \right) v_H.
\]

Sum up the two inequalities side by side to obtain

\[
t_L > \frac{2\theta_H}{1 + p + (1 - p)\lambda} v_L + \left( \theta_L \frac{\lambda + 1}{2} - \frac{2\theta_H}{1 + p + (1 - p)\lambda} \right) v_H > \frac{2\theta_H}{1 + p + (1 - p)\lambda} v_L,
\]

where the second inequality holds since \( \theta_L \frac{\lambda + 1}{2} \geq \theta_H > \frac{2\theta_H}{1 + p + (1 - p)\lambda} \).

Let us consider the PPE requirement with respect to \( R^\emptyset := \{\emptyset\} \), which requires to satisfy at least one of the conditions, \((FIC_L)\), \((FIR_L)\), \((FIC_H)\), \((FIR_H)\), and \((U)\), written as follows:

\[
\frac{t_L}{v_L} < \theta_L \frac{2}{\lambda + 1} \]  

(A46)

\[
\frac{t_H}{v_H} < \theta_L \frac{2}{\lambda + 1} \]  

(A47)

\[
\frac{t_L}{v_L} < \theta_H \frac{2}{\lambda + 1} \]  

(A48)

\[
\frac{t_H}{v_H} < \theta_H \frac{2}{\lambda + 1} \]  

(A49)

\[
U(R) \geq U(R^\emptyset) = 0 \]  

(A50)

First, (A46) and (A47) can be ignored since they are implied by (A48) and (A49). Given that \( \frac{2}{\lambda + 1} < \frac{2}{1 + p + (1 - p)\lambda} \) and \( \theta_H \frac{2}{\lambda + 1} < \theta_H \leq \theta_L \frac{\lambda + 1}{2} \), (A48) contradicts (A45) while (A49) contradicts (A41). Therefore, (A50) must hold. We prove below that (A50) cannot hold if either (i) \( p(\lambda - 1) \leq 1 \) or (ii) \( p(\lambda - 1) > 1 \) and \( p \geq \frac{\theta_L}{2\theta_H - \theta_L} \).
Let $h\theta$ Since the same quantities as $R_p(A39)$ and (A44) contradict each other, which means there does not exist a reverse-screening $R_p$. increases. We note that $U$ given the assumption that $U$ qualities as $21^2'\theta H(t_H - v_H) = \theta L_2^2v_H + \theta H(v_l - v_H)$. Note that due to (A41) and the first inequality of (A39), we have $t_H' < t_H$, $t_L' < t_L$, and $t_L' - t_H' \leq t_L - t_H$. Clearly, this implies that $U(R') > U(R)$. We now obtain

$$U(R') = v_H[\theta H - \theta L^1\frac{\lambda}{2}] + v_{LP}(\theta H - \theta L)[p(\lambda - 1) - \lambda].$$

Since $\theta H \leq \frac{\lambda}{2}\theta L$ and $p(\lambda - 1) < 1$, the expressions in both square brackets are negative, so $U(R) < U(R') < 0$, which contradicts (A50).

Case (ii): Define $R'' = \{(q_L, t''_L), (q_H, t''_H)\}$ to be a reverse-screening menu with the same qualities as $R$. where $t''_H = \theta L\frac{\lambda+1}{2}v_H$ and $t''_L = t''_H + \theta H(v_l - v_H) = \theta L\frac{\lambda+1}{2}v_H + \frac{2\theta H}{1+p+(1-p)\lambda}(v_l - v_H)$. It can be verified that due to (A10) and (A41), we have $t''_H < t_H$, $t''_L < t_L$, and $t''_L - t''_H \leq t_L - t_H$. Clearly, this implies that $U(R'') > U(R)$. We now show that $U(R'') < 0$ so (A50) cannot be satisfied. First, it can be shown that $U(R'')$ is decreasing as $\lambda$ increases.\footnote{This can be seen from observing that in the case $\theta H v_H \geq \theta L v_L$, we have} It thus suffices to show that $U(R'') < 0$ for the lowest $\lambda$, which is equal to $1 + \frac{1}{p}$ given the assumption that $p(\lambda - 1) \geq 1$. Setting $\lambda = 1 + \frac{1}{p}$, we obtain after rearrangement

$$U(R'') = -\theta L v_L + 2p^2(2\theta H - \theta L)(v_H - v_L) + p\theta L(-3v_H + 2v_L).$$

(A51)

Let $h(p)$ denote the numerator of this expression as a function of $p$. To show that $h(p) < 0$ for any $p \geq \frac{\theta L}{2\theta H - \theta L}$, observe that $h$ is a quadratic function maximized at $p = \frac{\theta L}{2\theta H - \theta L} \left(\frac{2v_l - 3v_H}{4v_H - 4v_l}\right) < 1$. Thus, for any $p \geq \frac{\theta L}{2\theta H - \theta L}$, $h(p) \leq h\left(\frac{\theta L}{2\theta H - \theta L}\right) = \frac{2\theta H v_H}{2\theta H + \theta L} < 0$.\hfill\Box

When $p(\lambda - 1) < 1$, the above argument and Claim 4 imply that (A44) must hold. But (A39) and (A44) contradict each other, which means there does not exist a reverse-screening PPE menu if $p(\lambda - 1) < 1$. Thus, the existence of reverse-screening PPE menu requires

$$\frac{\partial U(R'')}{\partial \lambda} = -\frac{\theta L v_H}{2} - p(1-p)(\theta_H v_H - \theta_L v_L) - \frac{2p(1-p)p\theta H (v_H - v_L)}{(1 + p + \lambda - p\lambda)^2} < 0,$$

We note that $U(R'')$ is also decreasing in the case $\theta H v_H < \theta_L v_L$, since, in that case,

$$\frac{\partial U(R'')}{\partial \lambda} = -\frac{\theta L v_H}{2} - p(1-p)(\theta_L v_L - \theta_H v_H) - \frac{2(1-p)p\theta H (v_H - v_L)}{(1 + p + \lambda - p\lambda)^2} < 0.$$
Lemma 4. There exists a reverse-screening PPE menu with $\theta_H v_H \geq \theta_L v_L$. The necessity proof is then completed by the result in the following lemma that the necessary condition does not get relaxed by considering a reverse-screening menu with $\theta_H v_H < \theta_L v_L$.

**Lemma 4.** There exists a reverse-screening PPE menu with $\theta_H v_H < \theta_L v_L$ only if $\lambda \geq \lambda_R$.

**Proof.** Fix any reverse-screening menu $R$ with $\theta_L v_L > \theta_H v_H$. We prove that (i) the inequalities (A6) and (A7) corresponding to $(IC_H)$ and $(IC_L)$ imply their counterparts in (A34) for a reverse-screening menu satisfying $\theta_H v_H \geq \theta_L v_L$; (ii) for each menu $R' = R^H, R^L, \text{or } R^\theta$, the inequalities corresponding to $(FIC)$, $(FIR)$, and $(U)$ conditions imply their counterparts for reverse-screening menu with $\theta_H v_H \geq \theta_L v_L$. Given (i) and (ii), the proof of Part (b) in Proposition 5 can be repeated to show that $\lambda \geq \lambda_R$ is also necessary for the existence of reverse-screening PPE menu satisfying $\theta_H v_H < \theta_L v_L$.

To show (i), consider any reverse-screening menu satisfying $\theta_L v_L > \theta_H v_H$ and write (A6) and (A7) as

\[
\frac{2\theta_H}{1+ p + (1-p)\lambda} + \frac{p(\lambda - 1) (\theta_L v_L - \theta_H v_H)}{(1+ p + (1-p)\lambda)(v_L - v_H)} \leq \frac{t_L - t_H}{v_L - v_H} \leq \frac{(\lambda + 1) \theta_L}{1+ p + (1-p)\lambda} - \frac{(1-p)(\lambda - 1) (\theta_L v_L - \theta_H v_H)}{(1+ p + (1-p)\lambda)(v_L - v_H)},
\]

which clearly implies (A34), given that $\theta_L v_L > \theta_H v_H$.

To show (ii), consider first the reference point $R^L = \{b_L\}$. It is straightforward to see that the conditions $(FIC_L)$, $(FIR_L)$, and $(FIR_H)$ are the same ss $(FIC_L)$, $(FIR_L)$, and
\((FIR_H)\) in (A35), (A36), and (A38), respectively. The condition \((FIC_H)\) is given as

\[
\frac{t_L - t_H}{v_L - v_H} > \frac{[1 + p + \lambda(1-p)]\theta_H}{2} + \frac{p(\lambda - 1)(\theta_L v_L - \theta_H v_H)}{2(v_L - v_H)},
\]

which implies \((FIC_H)\) in (A37). Condition \((U)\) is given as

\[
[1 - p(\lambda - 1)](t_L - t_H) \geq [1 - p(\lambda - 1)] \theta_H (v_L - v_H) + 2p(\lambda - 1)(\theta_L v_L - \theta_H v_H), \quad (A52)
\]

while \((U)\) in (A39) can be re-written as

\[
[1 - p(\lambda - 1)](t_L - t_H) \geq [1 - p(\lambda - 1)] \theta_H (v_L - v_H). \quad (A53)
\]

It is clear that neither condition holds when \(1 - p(\lambda - 1) < 0\) while (A53) always holds when \(1 - p(\lambda - 1) = 1\). Subtracting the RHS of (A53) from the RHS of (A52) yields

\[
2p(\lambda - 1)(\theta_L v_L - \theta_H v_H) > 0.
\]

Thus, (A52) implies (A53) when \(1 - p(\lambda - 1) > 0\).

Next let us consider \(R^H = \{b_H\}\). It is straightforward to see that \((FIR_L)\), \((FIC_H)\), and \((FIR_H)\) are the same as \((FIR_L)\), \((FIC_H)\), and \((FIR_H)\) in (A41), (A42), and (A43), respectively. \((FIC_L)\) is given as

\[
\frac{t_L - t_H}{v_L - v_H} < \theta_L \frac{1 + p + \lambda(1-p)}{1 + \lambda} - \frac{(\lambda - 1)(1-p)(\theta_L v_L - \theta_H v_H)}{(1 + \lambda)(v_L - v_H)},
\]

which implies \((FIC_L)\) in (A40), given that \(\theta_L v_L - \theta_H v_H > 0\). Condition \((U)\) is given as

\[
\frac{t_L - t_H}{v_L - v_H} \leq \theta_L - \frac{2(1-p)(\lambda - 1)(\theta_L v_L - \theta_H v_H)}{(1 + (1-p)(\lambda - 1))(v_L - v_H)},
\]

which implies \((U)\) in (A44).

Consider \(R' = R^\emptyset\). \((FIC)\) and \((FIR)\) are the same as their counterparts in the case \(\theta_H v_H \geq \theta_L v_L\), which are given in (A46) through (A49). \((U)\) is written as

\[
p(\theta_L v_L - t_L) + (1-p)(\theta_H v_H - t_H) - p(1-p)(\lambda - 1)(\theta_L v_L - \theta_H v_H + t_H - t_L) \geq 0
\]
while its counterpart in the case $\theta_H v_H \geq \theta_L v_L$ is

$$p(\theta_L v_L - t_L) + (1 - p)(\theta_H v_H - t_H) - p(1 - p)(\lambda - 1)(\theta_H v_H - \theta_L v_L + t_H - t_L) \geq 0.$$  

The latter inequality is implied by the former, given that $\theta_H v_H - \theta_L v_L < 0$. \hfill \qed

**Part (c):** Given $R = \{b = (q, t)\}$ with $q, t > 0$, the $(IR_L)$ constraint is $t \leq \theta_L \frac{1 + p}{1 + (1 - p) + p\lambda} v(q)$. Note that this is the only constraint needed for $R$ to be a PE. Given $R$, there are three possible deviations: $R' = \{\emptyset, \emptyset\}$, $\{\emptyset, b\}$, and $\{b, \emptyset\}$. First, it is straightforward to verify that $R$ always satisfies the PPE requirement with respect to $R' = \{b, \emptyset\}$.\footnote{More precisely, it is true that $R' = \{b, \emptyset\}$ must satisfy at least one of $(FIC_H)$ and $(FIC_L)$ conditions, that is $u(\emptyset|\theta_H, R') < u(b|\theta_H, R')$ and $u(b|\theta_L, R') < u(\emptyset|\theta_H, R')$.} Next, $(FIC_L)$ conditions for deviations $R' = \{\emptyset, \emptyset\}$ and $\{\emptyset, b\}$ are given respectively as $t_L < \theta_L \frac{1 + p}{1 + (1 - p) + p\lambda} v(q)$. Thus, for any $q > 0$, if we set $t = \theta_L k' v(q)$ for some positive constant $k' < \min\left\{\frac{2}{1 + \lambda}, \frac{1 + p + (1 - p)\lambda}{1 + (1 - p) + p\lambda}\right\}$, then $R = \{(q, t)\}$ is a pooling PPE menu. The profit from this menu is $\theta_L k' v(q) - cq$, which is positive for a sufficiently small $q$, due to the assumption that $\lim_{q \to 0} v'(q) = \infty$.

**Proof of Theorem 2**

We only need to prove part (b). The proof consists of two lemmas. In the first lemma, we consider a relaxed problem by weakening the PPE requirement as follows:

$$\max_{R = \{b_L, b_H\}} p(t_L - cq_L) + (1 - p)(t_H - cq_H) \quad \text{[P']},$$

subject to the constraints that $R$ is a PE menu and also satisfies the PPE requirement with respect to $R^L = \{b_L\}$, $R^H = \{b_H\}$, and $R^\emptyset_H := \{\emptyset, b_H\}$.

**Lemma 5.** If $\lambda < \lambda_S$, then the optimal menu that solves [Pˈ] must be a screening menu.

**Proof.** Recall from Lemma 3 that the necessary and sufficient condition for any screening menu $R$ to satisfy the PPE requirement with respect to $R^L$ and $R^H$ is given by (A33). Then, by Lemma 3, the (IC) constraints in (A5) are implied by (A33) and can thus be ignored.
Let us now turn to the PPE requirement with respect to \( R^\emptyset \), for which the conditions, \((FIC_L), (FIR_L), (FIC_H), (FIR_H)\), and \((U)\), are given as

\[
\frac{t_L}{v_L} < \frac{1 + p + (1 - p)\lambda}{1 + (1 - p) + p\lambda} = \frac{\theta_L}{B(p, \lambda)} \tag{A54}
\]

\[
\frac{t_H}{v_H} < \frac{\theta_H}{B(p, \lambda)} \tag{A55}
\]

\[
\frac{t_H - t_L}{v_H - v_L} > \frac{\theta_H}{B(p, \lambda)} \tag{A56}
\]

\[
\frac{t_H}{v_H} > \frac{\theta_H}{B(p, \lambda)} \tag{A57}
\]

\[
[1 - (1 - p)(\lambda - 1)] t_L \leq [1 + (1 - p)(\lambda - 1)] \theta_L v_L. \tag{A58}
\]

First, \((A56)\) contradicts \((IC_H)\) in \((A5)\). Second, \((A54)\) implies \((A58)\) and can thus be ignored. To see this, we can focus on the case \([1 - (1 - p)(\lambda - 1)] > 0\), so \((A58)\) can be rewritten as \(\frac{t_L}{v_L} \leq \frac{1 + (1 - p)(\lambda - 1)}{1 - (1 - p)(\lambda - 1)}\), which is then implied by \((A54)\) since \(\frac{1 + (1 - p)(\lambda - 1)}{1 - (1 - p)(\lambda - 1)} > \frac{1}{B(p, \lambda)}\) (as shown in the proof of Lemma 3). Next, \((A57)\) cannot hold. To see it, sum up \((A57)\) and \((IR_L)\) constraint, re-written as \(-t_L \geq -\theta_L \frac{\lambda + 1}{2} v_L\), side by side to obtain

\[
t_H - t_L > \theta_H \frac{1}{B(p, \lambda)} v_H - \theta_L \frac{\lambda + 1}{2} v_L.
\]

This inequality contradicts the second inequality of \((A33)\) since the RHS of the former is greater than that of the latter:

\[
\frac{\theta_H}{B(p, \lambda)} v_H - \theta_L \frac{\lambda + 1}{2} v_L - \theta_H \beta(p, \lambda)(v_H - v_L)
\]

\[
= \theta_H \left( \frac{1}{B(p, \lambda)} - \beta(p, \lambda) \right) v_H - \left( \theta_L \frac{\lambda + 1}{2} - \theta_H \beta(p, \lambda) \right) v_L 
\]

\[
\geq \theta_H \left( \frac{1}{B(p, \lambda)} - \beta(p, \lambda) \right) v_L - \left( \theta_L \frac{\lambda + 1}{2} - \theta_H \beta(p, \lambda) \right) v_L 
\]

\[
= \left( \frac{\theta_H}{B(p, \lambda)} - \theta_L \frac{\lambda + 1}{2} \right) > 0,
\]

where the first inequality holds since \(\frac{1}{B(p, \lambda)} \geq \beta(p, \lambda)\) (by Lemma 3) and \(v_H > v_L\). To see why the second (strict) inequality holds, consider first the case \(p \leq \frac{\lambda + 2}{\lambda + 3}\) so \(\alpha(p, \lambda) = \frac{\lambda + 1}{2}\). Then, we have \(\frac{\theta_H}{B(p, \lambda)} - \theta_L \frac{\lambda + 1}{2} \geq \theta_H \beta(p, \lambda) - \theta_L \alpha(p, \lambda) > 0\), where the second inequality holds since \(\lambda < \bar{\lambda}_S\). Consider next the case \(p \geq \frac{\lambda + 2}{\lambda + 3} > \frac{1}{2}\). Note that \(\frac{1}{B(p, \lambda)} > 1\) if \(p > \frac{1}{2}\). Thus,
\[
\frac{\theta_H}{B(p, \lambda)} - \theta_L \frac{\lambda + 1}{2} > \theta_H - \theta_L \frac{\lambda + 1}{2} > 0 \text{ since } \lambda < \bar{\lambda}_S < \bar{\lambda} = 2\frac{\theta_H}{\theta_L} - 1 \text{ implies } \theta_H > \theta_L \frac{\lambda + 1}{2}.
\]

In sum, either (A55) or (A58) must be satisfied. We show that any PPE menu satisfying (A55) is suboptimal for [\( P' \)]. For any such menu \( \tilde{R} \) with transfers \( \tilde{t}_L \) and \( \tilde{t}_H \), we must have
\[
\tilde{t}_H = \frac{\theta_L}{B(p, \lambda)} v_H \tag{A59}
\]
\[
\tilde{t}_L \leq \tilde{t}_H - \theta_L \alpha(p, \lambda)(v_H - v_L) < \frac{\theta_L}{B(p, \lambda)} v_H - \theta_L \alpha(p, \lambda)(v_H - v_L), \tag{A60}
\]
where the first inequality of (A60) is due to (A33). But, a higher profit is achieved by another menu \( R \) with the same quantities as in \( \tilde{R} \) but different transfers:
\[
t_L = \theta_L \alpha(p, \lambda)v_L \tag{A61}
\]
\[
t_H = t_L + \theta_H \beta(p, \lambda)(v_H - v_L) = \theta_L \alpha(p, \lambda)v_L + \theta_H \beta(p, \lambda)(v_H - v_L) \tag{A62}
\]
Note that \( R \) satisfies (A33). Also, \( R \) satisfies (IR\( L \)) and (A58) since they can be written together as \( t_L \leq \theta_L \alpha(p, \lambda)v_L \). Thus, \( R \) is a PE screening menu that satisfies the PPE requirement with respect to \( R^L, R^H, \) and \( R^0H \). Now, using (A59) through (A62), we obtain
\[
t_H - \tilde{t}_H > (\theta_H \beta(p, \lambda) - \theta_L \alpha(p, \lambda))v_L + \left( \theta_H \beta(p, \lambda) - \frac{\theta_L}{B(p, \lambda)} \right) v_H > 0 \tag{A63}
\]
\[
t_L - \tilde{t}_L > \theta_L \left( \alpha(p, \lambda) - \frac{1}{B(p, \lambda)} \right) v_H > 0, \tag{A64}
\]
where the last inequalities in (A63) and (A64) hold since \( \theta_H \beta(p, \lambda) > \theta_L \alpha(p, \lambda) \geq \frac{\theta_H}{B(p, \lambda)} \).

Thus, we can focus on (A58) to find the optimal menu for [\( P' \)].

Summing up, [\( P' \)] can be solved with (A33), (A58), and (IR\( L \)). Note that the latter two constraints can be written together as
\[
t_L \leq \theta_L \alpha(p, \lambda)v_L. \tag{A65}
\]

Then, the standard argument can be used to establish that (A65) and the second inequality of (A33) must hold as equality at the optimal menu that solves [\( P' \)],\footnote{Note that the second inequality of (A33) is strict for \( p > \frac{\lambda + 2}{\lambda + 3} \). Thus, the optimal menu fails to exist for the reason mentioned in footnote 14. We avoid the non-existence problem by allowing for the strict inequality to hold as equality.} implying that the transfers satisfy (A61) and (A62). Plugging them into the profit and taking the FOCs with
This condition is equivalent to requiring \( \lambda < \theta \) (20) to be smaller than that of (21), which yields \( \theta_H \beta(p, \lambda) > \theta_L \alpha(p, \lambda) \) after rearrangement. This condition is equivalent to requiring \( \lambda < \bar{\lambda}_S \).

We next show that the optimal menu in Lemma 5 satisfies all other PPE requirements.

**Lemma 6.** If \( \lambda < \bar{\lambda}_S \), then the optimal menu \( R \) that solves \([P']\) satisfies the PPE requirement with respect to all menus in \( C(R) \) other than \( R^L \), \( R^H \), and \( R^{0L} \).

**Proof.** (i) \( R' = R^\theta = \{\emptyset, \emptyset\} \): We consider two cases, \( p \geq \frac{1}{\lambda + 3} \) or \( p < \frac{1}{\lambda + 3} \). In the former case, \( R \) and \( R^\theta \) with transfers as in (A61) and (A62) satisfy \((FIC_H)\), \( u(\emptyset | \theta_H, R^\theta) < u(b_L | \theta_H, R^\theta) \), written as \( t_L < \theta_H \frac{2}{\lambda + 1} v_L = \theta_H \beta(p, \lambda) v_L \) for \( p \geq \frac{1}{\lambda + 3} \). To see this, given (A61), this inequality becomes \( \theta_L \alpha(p, \lambda) v_L < \theta_H \beta(p, \lambda) v_L \), which holds since \( \lambda < \bar{\lambda}_S \).

When \( p < \frac{1}{\lambda + 3} \), we show that \( R \) and \( R^\theta \) satisfy \((U)\), \( U(R) \geq U(\emptyset) = 0 \). Write first the ex ante utility from \( R \) as

\[
U(R) = p(\theta_L v_L - t_L) + (1 - p)(\theta_H v_H - t_H) - p(1 - p)(\lambda - 1)(\theta_H v_H - \theta_L v_L + t_H - t_L). \tag{A66}
\]

Note that with \( p < \frac{1}{\lambda + 3} \), (A61) and (A62) become

\[
t_L = \theta_L \frac{\lambda + 1}{2} v_L \quad \text{and} \quad t_H = \theta_L \frac{\lambda + 1}{2} v_L + \theta_H \frac{1 - p(\lambda - 1)}{1 + p(\lambda - 1)}(v_H - v_L).
\]

Plug these into (A66) to express \((U)\) as

\[
U(R) = \frac{1}{2} v_L \left( 2(1 - p)\theta_H [1 - p(\lambda - 1)] - \theta_L [1 + 2p^2(-1 + \lambda) + \lambda - 2p\lambda] \right) \geq 0.
\]

With \( p < \frac{1}{\lambda + 3} < \frac{1}{\lambda - 1} \), the expression in the first square bracket is positive and also the fact that \( \theta_L \alpha(p, \lambda) = \theta_L \frac{\lambda + 1}{2} < \frac{1 - p(\lambda - 1)}{1 + p(\lambda - 1)} \theta_H = \theta_H \beta(p, \lambda) \) means \( \theta_H > \frac{\theta_L \lambda(1 + \lambda)}{2(1 + p - p\lambda)} \). Thus,

\[
U(R) > \frac{1}{2} v_L \left( 2(1 - p) \left( \frac{\theta_L \lambda(1 + \lambda)}{2(1 + p - p\lambda)} \right) [1 - p(\lambda - 1)] - \theta_L [1 + 2p^2(-1 + \lambda) + \lambda - 2p\lambda] \right)
\]

\[
= \frac{1}{2} p \theta_L v_L (\lambda - 1)(2 + \lambda - p(3 + \lambda)) > 0,
\]

where the last inequality follows from \( p < \frac{1}{\lambda + 3} < \frac{1 + 3}{\lambda + 3} \).

(ii) \( R' = R^{0L} = \{\emptyset, b_L\} \): Consider the condition \((FIC_H)\), \( u(b_H | \theta_H, R^{0L}) > u(b_L | \theta_H, R^{0L}) \),
which can be written as
\[
\frac{t_H - t_L}{v_H - v_L} < \theta_H \frac{2}{\lambda + 1}.
\] (A67)

If \( p > \frac{1}{\lambda+3} \), then this condition is satisfied by \( t_L \) and \( t_H \) as in (A61) and (A62) since \( \frac{t_H - t_L}{v_H - v_L} = \theta_H \beta(p, \lambda) = \theta_H \frac{2}{\lambda+1} \) for \( p > \frac{1}{\lambda+3} \).\(^{27}\) Suppose from now that \( p \leq \frac{1}{\lambda+3} \). We show that \( U(R) \), that is, \( U(R) \geq U(R^{0L}) \), is satisfied. To do so, we obtain after simplification of terms

\[
U(R) - U(R^{0L}) = \frac{v_L}{2} \left( \theta_H \left[ 1 - 2p(2 + p(\lambda - 1) - \lambda) \right] (\lambda + 1) + \theta_L \left[ -\lambda - 1 + p(2 + p(-1 + \lambda)^2 - (-3 + \lambda)\lambda) \right] \right).
\]

First, we define the expression in the first square bracket as \( h(p) := 1 - 2p(2 + p(\lambda - 1) - \lambda) \) and show that \( h(p) > 0 \) for \( p \in [0, \frac{1}{\lambda+3}] \). Since \( h \) is a concave, quadratic function of \( p \), it suffices to show that both \( h(0) \) and \( h(\frac{1}{\lambda+3}) \) are positive: \( h(0) = 1 > 0 \) and \( h(\frac{1}{\lambda+3}) = \frac{3\lambda(\lambda+2)-1}{(3+\lambda)^2} > 0 \). Given that \( h \) is positive for \( p \in [0, \frac{1}{\lambda+3}] \), we have

\[
U(R) - U(R^{0L}) > \frac{v_L}{2} \left( \theta_L \left[ 1 - 2p(2 + p(\lambda - 1) - \lambda) \right] (\lambda + 1) + \theta_L \left[ -\lambda - 1 + p(2 + p(-1 + \lambda)^2 - (-3 + \lambda)\lambda) \right] \right) = p\theta_L(\lambda - 1)(\lambda + 2 - p(\lambda + 3)) > 0
\]

if \( p \leq \frac{1}{\lambda+3} \), as desired.

(iii) \( R' = R^{HL} = \{b_H, b_L\} \): This menu corresponds to a reverse-screening menu where the high (low) type chooses a bundle with low (high) quality. By Lemma 2, this menu can only be a PE if \( \theta_H \leq \theta_L \frac{\lambda+1}{\lambda} \), which contradicts with the assumption that \( \lambda < \lambda_S < \lambda = 2\theta_L - 1 \).

(iv) \( R' = R^{H\emptyset} = \{b_H, \emptyset\} \): Write \( (FIC_L) \) and \( (FIC_H) \)—that is, \( u(b_H|\theta_L, R^{H\emptyset}) < u(\emptyset|\theta_L, R^{H\emptyset}) \) and \( u(\emptyset|\theta_H, R^{H\emptyset}) > u(b_H|\theta_H, R^{H\emptyset}) \)—as

\[
\frac{t_H}{v_H} > \theta_L \frac{1 + (1 - p) + p\lambda}{1 + p + (1 - p)\lambda} \quad \text{and} \quad \frac{t_H}{v_H} < \frac{2\theta_H + p(\lambda - 1)\theta_L}{1 + p + (1 - p)\lambda}.
\]

\(^{27}\)To be precise, the transfers \( t_L \) and \( t_H \) in (A61) and (A62) result from binding the second inequality of (A33) to avoid the non-existence problem (as mentioned in Remark 14). In fact, for \( p > \frac{1}{\lambda+3} \), that inequality is strict and corresponds to (A29), which is the same as (A67).
respectively. One of these two inequalities must hold since

$$\frac{2\theta_H + p(\lambda - 1)\theta_L}{1 + p + (1 - p)\lambda} - \theta_L \frac{1 + (1 - p) + p\lambda}{1 + p + (1 - p)\lambda} = \frac{2(\theta_H - \theta_L)}{1 + p + (1 - p)\lambda} > 0.$$  

(v) $R' = R^{L0} = \{b_L, \emptyset\}$: The analysis of this case is analogous to the case (iv) above and thus omitted.
