Abstract
This study was carried out to examine the mechanical properties of hypereutectic Al–16% Si alloy with the introduction of zinc oxide (ZnO) nanoparticles (NPs) synthesized by simple sol–gel method. The microstructure of the synthesized ZnO NPs was characterized by X-ray diffraction (XRD) and transmission electron microscopy (TEM). The microstructure of the synthesized ZnO NPs reflects the formation of the wurtzite-type ZnO and the average crystallite sizes around 35 nm. Hypereutectic Al–16% Si with varies concentration of ZnO NPs (0.5, 1, 1.5 and 3%) was synthesized utilizing permanent mold casting technique. Energy-dispersive spectrometer (EDS) and scanning electron microscopy (SEM) of hypereutectic Al–16 wt% Si alloys after the dispersion of these nanoparticles were analyzed. The results revealed that an addition of ZnO nanoparticle to hypereutectic Al–16wt % Si alloy enhanced the tensile strength, impact energy and the hardness. The maximum tensile strength, impact energy and hardness of this alloy was 200 MPa, 5.38 J, 60 BHN, respectively, which occurred at 3 wt% of ZnO NPs. This enhancement in mechanical properties can attributed to the decomposition and dissolution of the nano-oxide particles in aluminum alloy melt and grain growth restriction.

1 Introduction

Hypereutectic Al–Si alloys have a good castability, high stiffness, best temperatures strength, high electrical conductivity, good corrosion, and wear resistance so was most widely utilized in the industrial applications especially in the engine components such as head cylinder, valves, engine block, pistons and in electrical applications such as the electrical transmission lines [1–5]. Hypereutectic Al-Si alloys have a wide range of use and therefore we must work to improve the mechanical properties. The examination of addition of nanoparticles on the microstructure and the mechanical properties of this alloy is important. Among nanoparticles, zinc oxide (ZnO) is considered a semiconductor material, self-activated crystal, and multi-functional because of low dielectric constant, high catalytic activity, more economical and wide band gap around 3.37 eV with high exciting binding energy [6–8]. Therefore, this is used in field of nanotechnology science to improve material operation and machines in the nanometer scale by various techniques; in addition, it is used in solar cell, solid-state gas sensor, nanowire, electronic nanodevices, UV lasing diode, nanoresonators, and piezoelectric transducers [9–12]. Raghukiran et al. [13] studied the effect of the scandium addition on the mechanical and wear behavior of Al–x%Si–0.8Sc alloys. The results show the Al–x%Si–0.8Sc alloys give higher tensile strength and flow stress, and an improvement in the wear behavior at low concentration ratio of silicon for ternary alloys. In addition, the effect of scandium on hardening and composition of the Al–Ca eutectic alloys were investigated by Blow et al. [14]. It was found the scandium addition to this alloy does not leave an influence on the strengthening. Hengcheng et al. [15] investigated the effect of an addition of strontium on grain structure of Al–13 wt% Si alloy. It was observed that the eutectic grain structure was refined with an addition in Sr and the faster cooling rate leads to the increasing in eutectic nucleation rate. El-Mahallawi et al. [16] used three types of nanoparticles such as (Al2O3), titanium dioxide (TiO2) and zirconia (ZrO2) to improve the properties of A356 aluminum alloys. There is an enhancement in the mechanical properties with an addition of nanoparticles of Al2O3, TiO2, and ZrO2 at stirring temperature and...
speed 600 °C, 1500 rpm, respectively. The microstructure of aluminum alloy (A356) is transformed to more fine structure and improved mechanical properties due to introduction nanocrystalline oxide particles (ZnO,~ 20 nm in size) [17]. Qasim et al. [18] investigated the mechanical properties of Al 356 casting alloys filled by ZnO nanorods. It was indicated that mechanical properties such as tensile strength, hardness, and ductility were good enhanced significantly after adding the nanorods ZnO to Al alloys. Jabeera et al. [19] investigated the mechanical properties of the aluminum zinc alloy anodes reinforced with the ZnO nanoparticles. An enhancement in the galvanic performance and metallurgical properties of the Al alloy anodes was observed. The improvement in the mechanical properties depends on the dispersion of NPs through Al matrix. The main reason for the improvement of the mechanical properties of aluminum alloys due to the introduction of nanoparticles can be attributed to the restriction of aluminum growth during solidification [20]. This work focuses on studying the mechanical properties of hypereutectic Al–16% Si alloy based on zinc oxide (ZnO) NPs synthesized by simple sol–gel method with varied concentrations 0.5, 1.0, 1.5 and 3 wt%. In addition, the dependency of aluminum growth on ZnO NP concentration was examined. The correlation between mechanical properties and the microstructure is investigated through study.

2 Experimental procedure

2.1 Zinc oxide nanocrystalline synthesis

ZnO nanocrystalline powder has been synthesized using sol–gel mechanism. Materials used in synthesis include zinc acetate dehydrate [Zn(CH3COO)2 ⋅ H2O], isopropanol, and diethanolamine [HN(CH2-CH2OH)2, DEA]. The reagents, provided in analytical grade, were utilized without further purification. First, solution which consists of 6.585 g of Zn(CH3COO)2 ⋅ H2O and 75 mL of isopropanol was stirred at room temperature. The dimension of the sample was 165 mm length; 19 mm width and 5 mm thickness, Fig. 1. For accurate results, four measurements were done for each sample and the average final tensile strength was calculated. The microstructure of the synthesized ZnO NP powder was analyzed using a JEOL 6060 scanning electron microscope coupled with an energy-dispersive spectroscopy (EDS) chart.

2.2 Preparation of nanocomposite

Hypereutectic Al–16% Si alloy was utilized as a base material in this study. Zinc oxide nanopowders were used as reinforcement phase at different weight concentration from 0.5 to 3%. The chemical composition analysis of the base material is summarized in Table 1 [20].

Permanent mold casting technique (PM) was used to produce the hypereutectic Al–16 Si %. The more details about the casting procedure and the cooling conditions were presented in the previous work [20]. The concentrations of ZnO NPs in investigated alloy were 0.5, 1.0, 1.5 and 3 wt%. The desired amount Al–16% Si alloy and synthesized ZnO NPs were total mass 1 kg. The wanted mass of hypereutectic Al–16% Si alloy was placed into the copper crucible of the electrical furnace after cutting it into small pieces and primates to melt inside the furnace up to 710 °C. Then ZnO nanoparticles with different weight percent was added to the Al–16 Si % alloy in the liquid or semisolid state at 750 °C and mixing with Al–16 Si alloy molten into the copper crucible and stirred manually for 5 min after the addition of the ZnO nanoparticles. Finally, the melt was pouring manually inside the metal mold. Al–Si alloy specimens before and after ZnO nanoparticles addition samples were cutting according to ASTM standard.

The microstructure of the hypereutectic Al–16% Si alloy with and without ZnO nanoparticles was analyzed using a JEOL 6060 scanning electron microscope coupled with an energy-dispersive spectroscopy (EDS) chart. The microstructure of the hypereutectic Al–16% Si alloy with and without ZnO nanoparticles was evaluated in a JEOL 6060 scanning electron microscope coupled with an energy-dispersive spectroscopy (EDS) chart.

2.3 Mechanical testing

Tensile test was performed using the universal testing machine (TQSM 1000), according to ASTM D638 standard to determine the tensile strength of the hypereutectic Al alloy without and with ZnO nanoparticles addition from 0.5 to 3 wt% at room temperature. The dimension of the sample was 165 mm length; 19 mm width and 5 mm thickness, Fig. 1. For accurate results, four measurements were done for each sample and the average final tensile strength was calculated.

Brinell hardness testing machine utilizing a 10-mm-diameter hardened steel ball and 125 kgf applied load carried out the hardness test. The toughness of Al alloy

### Table 1 Chemical composition of Al–16 wt% Si alloys [20]

| Composition | Cu  | Si  | Mg  | Fe  | Mn  | Al |
|-------------|-----|-----|-----|-----|-----|----|
| Al–16% Si   | 0.008 | 16   | 0.019 | 0.29 | 0.002 | Bal |

λ = 0.15406 nm, at a power of 1600 W (40 kV and 40 mA). The microstructure of the synthesized ZnO NP powder was investigated by high-resolution transmission electron microscope HR-TEM of model JEM-2100 with acceleration voltage up to 200 kV.
reinforced by ZnO nanoparticles was obtained by examining the impact energy of this alloy using Charpy impact tester according to ASTM D256 standard. The specimen used in this test was (15 × 15), thickness 4 mm and the pre-crack length was 2 mm.

3 Results and discussion

3.1 Structure of the obtained ZnO NPs

Figure 2 shows XRD pattern of the synthesized ZnO powder. The XRD pattern of ZnO powder detects the formation of pure ZnO with wurtzite structure type based on standard crystallographic data in the reference pattern (JCPDS 36-1451). The crystallite size \( D \) of the synthesized powder was evaluated from X-ray line broadening using Scherrer’s equation [21, 22]:

\[
D = \frac{0.9 \lambda}{\beta \cos \theta},
\]

where \( \lambda \), \( \beta \) and \( \theta \) are the X-ray wavelength, the full width at half maximum (FWHM) of the diffraction peak and the Bragg diffraction angle, respectively. The average-evaluated \( D \) values for all recorded diffraction lines is 32.5 nm and the wurtzite lattice parameters \( a \) and \( c \) are 0.3242 nm and 0.5195 nm, respectively, which are close to the standard data (\( a = 0.32488 \) nm and \( c = 0.52066 \) nm) card no JCPDS-36-1451.

Figure 3 shows TEM image of the synthesized ZnO NPs. Figure 3 reflects that the obtained shape of the synthesized ZnO is hexagonal shape with large uniformity.

3.2 Microstructure

Figure 4a–d shows the influence of zinc oxide nanoparticle addition on the microstructure of hypereutectic Al–16% Si alloy, analyzed by the SEM micrographs. It was found that from Fig. 4a, there are large voids, and cracks in the base material (without ZnO nanoparticles). The introduction of ZnO NPs into hypereutectic Al matrix may reduce these voids and cracks in this alloy. The introduction of ZnO NPs in Al–16% Si alloy leads to decrease the grain size of primary Al as shown in Fig. 4a–d. This decrease in grain size was highly observed at high concentration of NPs. The Al–16 Si % alloy was refined in the microstructure by reaction between ZnO NPs and Al, so the strength of the grain

Fig. 1 Dimension of tension test specimen

Fig. 2 XRD pattern of the obtained ZnO NPs

Fig. 3 TEM image of the obtained ZnO NPs
boundaries may be enhanced. NPs with high surface area have high reaction with aluminum due to high interfacial zone between them. For high concentration of ZnO NPs (3%), the reaction reaches high value so this sample has highest refinement in microstructure. The refinement of Al by addition of varied elements can be attributed to growth restriction factor and heterogeneous nucleation [17, 18]. More deeply, the addition of ZnO NPs to solution of Al–16 Si % alloy at high temperature leads to decomposition of ZnO NPs to Zn and O. Almost all oxygen after decomposed from ZnO NPs was combined with aluminum oxide. The presence of oxygen decomposed from ZnO NPs at interface between liquid and solid of Al through growth of primary aluminum alloy leads to restrict growth. The restriction of aluminum growth during solidification can be attributed to diffusion of solute Zn at interfacial between solid and liquid of aluminum. In addition, both oxygen and Zn resulted from decomposition are considerable for heterogeneous nucleation of primary aluminum grain.

Figure 5a, b shows SEM and EDX for sample with 3% ZnO NPS. The formation of Al₂O₃, found in eutectic region, indicates the restriction of growth. The presence of zinc metal and absence of zinc oxide from EDX chart are a clear evidence of decomposition of zinc oxide.

3.3 Mechanical behavior

Mechanical behavior of the hypereutectic Al–16% Si alloy after adding the varying percentages of ZnO nanoparticles (0.5, 1, 1.5 and 3 wt%) was investigated by tensile, impact strength and hardness tests and is summarized in Table 2.

Tensile strength and impact energy of hypereutectic Al–16 Si alloy were enhanced significantly after ZnO nanoparticle addition as shown in Fig. 6 and Table 2. It was observed that the largest value of the tensile strength and impact energy of this alloy was reached at 200 MPa and 5.38 J, respectively, at 3% ZnO nanoparticle addition. Further, the increase in tensile strength with concentration of ZnO nanoparticles attributed to refinement of grain size, discussed in previous section, and the strong interface zone between the nanoparticles and Al matrix due to uniform distribution of NPs inside the Al alloy matrix would lead to an improvement in tensile strength of Al alloy. The highest enhancement in tensile strength was occurred at 3% of ZnO NPs because high refinement of aluminum alloy which means smaller grain size of aluminum.

Also, the impact energy of hypereutectic Al alloy increases with the ZnO nanoparticle concentration increase from 0.5 to 3 wt%. The maximum impact energy occurs with
3 wt% of ZnO nanoparticles. This increase in the impact energy attributed to the good dispersion of the nanoparticle ZnO in Al matrix.

Figure 7 shows the effect of zinc oxide nanoparticle addition on the hardness value (BHN) of hypereutectic Al–16 Si alloy. The hardness value of base Al–16 Si % alloy (0% nanoparticle ZnO) was 46.3 BHN. It has been observed that the hardness value increased with an increasing in ZnO nanoparticle addition. It can be attributed to the refinement of aluminum alloy and the presence of harder and strong zinc oxide nanoparticles, which can withstand the deformation under the effect of indentation loads. The hardness of the Al–16% Si alloy at 3 wt% addition of nanoparticle ZnO was reached to maximum value at 60 BHN. The hardness of the Al–16 Si alloy with addition 1.50% ZnO nanoparticles was 15% higher than that the base Al–16 Si alloys.
4 Conclusions

The effect of ZnO NP content from 0 to 3% on the microstructure and mechanical characteristic of hypereutectic Al–16 Si% alloy were studied. The refinement of this alloy was detected due to ZnO NP introduction and maximum refinement was observed at 3% NP concentration. Decomposition of ZnO NPs through Al–16 Si% alloy leads to refinement and small grain size of Al alloy. Mechanical characteristics of the hypereutectic Al–16 Si% alloy were enhanced after zinc oxide nanoparticle addition in weight percent from 0.5 to 3%. Enhancement in mechanical properties reaches to highest value at 3% NP concentration.
