Background: Estimates of disease burden in Nepal are based on cross-sectional studies that provide inadequate epidemiological information to support public health decisions. This study compares the health and demographic indicators at the end of 2012 in the Jhaukhel-Duwakot Health Demographic Surveillance Site (JD-HDSS) with the baseline conducted at the end of 2010. We also report on the use of skilled birth attendants (SBAs) and associated factors in the JD-HDSS at the follow-up point.

Design: We used a structured questionnaire to survey 3,505 households in the JD-HDSS, Bhaktapur, Nepal. To investigate the use of SBAs, we interviewed 434 women who had delivered a baby within the prior 2 years. We compared demographic and health indicators at baseline and follow-up and assessed the association of SBA services with background variables.

Results: Due to rising in-migration, the total population and number of households in the JD-HDSS increased (13,669 and 2,712 in 2010 vs. 16,918 and 3,505 in 2012). Self-reported morbidity decreased (11.1% vs. 7.1%, respectively), whereas accidents and injuries increased (2.9% vs. 6.5% of overall morbidity, respectively). At follow-up, the proportion of institutional delivery (93.1%) exceeded the national average (36%). Women who accessed antenatal care and used transport (e.g. bus, taxi, motorcycle) to reach a health facility were more likely to access institutional delivery.

Conclusions: High in-migration increased the total population and number of households in the JD-HDSS, a peri-urban area where most health indicators exceed the national average. Major morbidity conditions (respiratory diseases, fever, gastrointestinal problems, and bone and joint problems) remain unchanged. Further investigation of reasons for increased proportion of accidents and injuries are recommended for their timely prevention. More than 90% of our respondents received adequate antenatal care and used institutional delivery, but only 13.2% accessed adequate postnatal care. Availability of transport and use of antenatal care was associated positively with institutional delivery.

Countries in Asia and Africa frequently lack reliable national data. Therefore, many national and global estimates of population health have relied on extrapolation and modeling approaches using limited data (1). Byass and colleagues reported that detailed local data, such as those produced by health demographic surveillance sites (HDSS), are likely to adequately reflect national data, making them suitable for generalizing into
policy (2). This finding is very important in countries like Nepal, where the scarcity of reliable and accurate longitudinal data inhibits development of evidence-based policy (2).

Estimates of disease burden in Nepal are based on cross-sectional studies, including a national census every 10 years, a national demographic and health survey every 5 years, and additional studies conducted by the Ministry of Health and Population and other agencies. These data provide inadequate epidemiological information to support critical decisions by health planners, policy makers, and managers (3).

Although Nepal’s vital records system gathers continuous data on births, deaths, and marriage formation and dissolution, coverage is poor, registering only just over one-third of all births (4). Compared to periodic retrospective surveys, an HDSS ensures more accurate records over time, especially in a population where education levels are low (4).

In 1996, a household registration system including demographic surveillance system methodology and focusing on migration issues was established in Chitwan, a southern district in central Nepal (4). We established the Jhaukhel-Duwakot HDSS (JD-HDSS) in 2010 in the Jhaukhel and Duwakot Village Development Committees (VDCs) of Bhaktapur District (3).

In countries with a weak vital registration system, an HDSS can provide data on vital events and a sampling frame for health research (5). We conducted a study on smoking susceptibility among adolescents in the JD-HDSS in October–November 2011 (6) and another study on cardiovascular health knowledge, attitude, and behavior in September–November 2011 (7). We also explored community experiences and perceptions about the causes and prevention of cardiovascular disease among people with cardiometabolic conditions (8).

As Nepal strives to attain the Millennium Development Goals (MDGs), the government is committed to increasing the proportion of births attended by skilled birth attendants (SBAs) (9). Although SBA coverage has increased nationally, from 9% in 1996 to 36% in 2011 (10, 11), Nepal still lags behind the 60% compliance target set by the World Health Organization for 2015 (9). Women’s use of SBAs is unevenly distributed between rural and urban areas. Indeed, the recent Nepal Demographic and Health Survey showed that 27.9% of deliveries in urban areas and 66.7% of deliveries in rural areas occur at home (12). With less than 6 months remaining to achieve the MDG targets, the issues surrounding SBA services remain pertinent in the post-MDG health and development agenda.

An HDSS starts with a baseline survey and then conducts a follow-up survey to gather health and demographic indicators (i.e. fertility, migration, morbidity, and mortality) (13). Baseline surveys are useful for examining the access, quality, and utilization of health-care services (14). This study compares the health and demographic indicators at the end of 2012 in the JD-HDSS with the baseline survey conducted at the end of 2010.

Earlier studies on SBA services focused mostly on rural areas (15–19). Our follow-up survey assessed the use of SBA services and associated factors in the peri-urban JD-HDSS.

Methods

Study site and population

The Duwakot and Jhaukhel VDCs lie in the mid-hills of Bhaktapur District adjacent to Kathmandu, the capital city of Nepal. Both VDCs represent prototypical urbanizing villages near Nepal’s larger towns. We previously described the setting of the JD-HDSS (3). We conducted a complete enumeration of the population residing in the surveillance site. Our follow-up survey on SBA usage included all married women of reproductive age who had delivered a baby during the two years prior to data collection.

Recruitment and training of field staff

A core local management committee comprising four PhD students and a coordinator planned, organized, and oversaw HDSS activities. We recruited and trained 18 enumerators and 4 supervisors to execute the field survey. Enumerator training included instructions for conducting data collection and an explanation of each section of the collection tools that were developed from the baseline questionnaire. All enumerators and supervisors received a field manual that provided specific instructions on how to complete the questionnaire interview forms. Enumerator training also included a pretest of the collection tools.

Data collection and field supervision

We based the follow-up questionnaire on our original baseline survey (3). In addition to socioeconomic information, demographic parameters, morbidity, health-seeking behaviors, and environmental factors, we used a separate structured questionnaire to determine use of SBAs and associated factors. Enumerators recorded any respondent illnesses that occurred in the 4 weeks preceding the survey. We coded each response for data entry.

Nine groups of enumerators (two enumerators per group) collected household data. Four field supervisors (two per VDC) were available in the field during the entire collection period to supervise and support the enumerators. The field supervisors regularly reported the status of data collection to the PhD students.

The PhD students (BC, BS) supervised data collection during regular field visits. Several meetings with the enumerators and field supervisors helped identify problems and correct errors. The PhD students’ academic supervisors (AK, MP, SO) provided overall guidance.
**Data management and analysis**

Public health graduates entered the data using EpiData software, version 3.1. We checked the data entry process regularly and discussed with data entry operators any problems they faced during data entry. Then, data were transferred into IBM SPSS Statistics, version 20, for analysis.

The fertility and mortality indicators were calculated based on the measurement of occurrence of such events within 1 year preceding the survey. Those residents who moved into the surveillance site at least 3 months prior to data collection were considered in-migrants, whereas those who left the surveillance site for 3 months or longer were considered out-migrants.

Data analysis involved both descriptive (percentage, mean, standard deviation) and inferential statistics (95% CI for differences, logistic regression). We compared demographic parameters, morbidity, health-seeking behaviors, and environmental factors with data from the baseline survey.

Principal component analysis (20) determined household economic status by calculating a wealth index based on household assets. The wealth index was computed using the first principal component and based on the availability of 17 kinds of household assets.

We employed multivariate logistic regression analysis to assess the association of antenatal, delivery, and postnatal care with independent variables (education, occupation, ethnicity, age, wealth quintile, and means of transport). To check collinearity, we calculated the variance inflation factor (VIF) and detected no problem among the independent variables (highest VIF, 1.15) that would prevent their inclusion in analysis. Multivariate logistic regression analyses included all independent variables that were significant at the 15% (21) level in the bivariate logistic regression analyses.

**Ethical considerations**

After explaining the nature of the study, its rationale, and the extent of participant involvement, the enumerators sought verbal informed consent from every participant. The Nepal Health Research Council granted ethical approval for this study. We also briefed local administrative authorities, health personnel, and political leaders about the objectives of our study and obtained their verbal permission to conduct the survey. To ensure confidentiality, all data were secured in the HDSS office at Jhaukhel, Bhaktapur.

**Results**

**Sociodemographic indicators**

Data from Nepal’s 2011 national census indicates that the JD-HDSS covers 5.55% of the total population of Bhaktapur District (22). Between the baseline and follow-up surveys (2010 and 2012, respectively), the total population of the JD-HDSS increased by 23.7% (Table 1). Mean age in the follow-up survey was similar for both sexes (29.5 ± 18.6 years for males and 29.9 ± 18.7 years for females). Compared to the baseline survey, the proportion of children <5 years of age increased from 5.8 to 6.3%, as did the proportion of people aged ≥70 years (3.0 to 3.3%).

At follow-up, one-third (33.1%) of the population belonged to the Newar caste, followed by Chhetri (31.6%) and Brahmin (21.8%). Disadvantaged Janajati (Tamang, Magar, and Rai) and lower caste (Dalit) accounted for 8.7 and 2.8% of the total population, respectively. Similar to the finding at baseline (97%) the predominant religion was Hindu (95.6%), followed by Buddhism (2.6%) and Christianity (1.7%). The proportion of illiterate people aged ≥6 years decreased (18.2% at baseline vs. 16.4% at follow-up, data not shown). The proportion of illiterate people aged ≥15 years was 19.4%.

More than one-third of the population (35.4%) had completed secondary-level education (Grade 10), and 1.8% had completed master’s level education. Although the percentage of people working in agriculture remained unchanged (10.6%), the population working in the service sector decreased (20.0% at baseline vs. 15.5% at follow-up). The proportion of unemployed people decreased (2% at baseline vs. 1% at follow-up).

**Fertility**

Although we determined a small increase in the crude birth rate (9.7 vs. 11.7 per 1,000 population), the change was not statistically significant (Table 2). The mean age of girls at marriage increased (18.4 years at baseline vs. 19 years at follow-up); the mean age at first childbirth was 20 years in both surveys.

**Migration**

With 1,783 in-migrants (10.5%) in the follow-up survey, immigration to the JD-HDSS increased more than fourfold.

Table 1. Household size, population size, and sex ratio in the Jhaukhel-Duwakot Health Demographic Surveillance Site during 2010 and 2012

| Variable                     | 2010     | 2012     |
|------------------------------|----------|----------|
| Total households             | 2,712    | 3,505    |
| Total population             | 13,669   | 16,918   |
| Males                        | 6,868    | 8,516    |
| Females                      | 6,801    | 8,402    |
| Sex ratio (males per female) | 1.010    | 1.002    |
| Sex ratio at birth (males per female) | NA | 1.64:1 |
| Median family size           | 5.0 (1-21) | 4.0 (1-18) |

Note: Data are shown as a comparison of general characteristics of the study population between the baseline survey in 2010 (3) and follow-up survey in 2012. NA, not available.
(2.3% at baseline vs. 10.5% at follow-up), which was statistically significant (Table 2). The main reasons for in-migration were service (33.3%), business (11.7%), and study (8.9%). The proportion of males was higher than females among the in-migrants (63.9% vs. 36.1%). Out-migrants at follow-up totaled 462 (2.7%), which was greater but not significant compared to baseline (1.4%) (Table 2). The main reasons for out-migration were service (57.0%) and study (21.9%). More males than females out-migrated from the surveillance site (78.8% vs. 21.2%).

Mortality, morbidity, and health behaviors
The crude death rate was almost the same (3.9 and 3.8 per 1,000 population, respectively) in both surveys. In the follow-up, a total of 65 deaths were reported with 57% male and 43% female deaths. Both surveys recorded no infant or maternal deaths.

Reported morbidity decreased significantly (Table 2). Although the position of top two morbidities (respiratory diseases and fever) remained unchanged, respiratory diseases increased and fever decreased in proportion to the overall morbidity (Table 3). The proportion of accidents and injuries contributing to overall morbidity increased (2.9% vs. 6.5%, respectively). Gastrointestinal problems increased (13.9% vs. 18.1%), propelling them to the third leading cause of morbidity in the follow-up survey. Additionally, morbidity resulting from the four main non-communicable diseases (heart disease, hypertension, cancer, and diabetes) declined (12% vs. 5.7%, respectively).

Regarding treatment-seeking behavior, more than one in five respondents (22.7%) in the follow-up survey had

| Variable                      | 2010 | 2012 | Difference | Lower CI | Upper CI |
|-------------------------------|------|------|------------|----------|----------|

Note: Data show a comparison of vital statistics between the baseline (3) and follow-up survey. CI, confidence interval; *p < 0.05; a no infant or maternal deaths were reported during the survey period.

Table 3. Top morbidity conditions reported in the Jhaukhel-Duwakot Health Demographic Surveillance Site, 2010 and 2012

| Ranking | 2010 (N = 1,517) | 2012 (N = 1,142) |
|---------|-----------------|-----------------|
| 1       | Respiratory diseases (41.9) | Respiratory diseases (48.4) |
| 2       | Fever (41.1)    | Fever (24.5)    |
| 3       | Headache and dizziness (16.7) | Gastrointestinal problems (18.1) |
| 4       | Bone and joint pain (14.4) | Bone and joint pain (13.4) |
| 5       | Gastrointestinal problems (13.9) | Accidents and injuries (6.5) |
| 6       | Heart diseases, including hypertension (8.8) | Heart diseases, including hypertension (4.9) |
| 7       | Accidents and injuries (2.9) | Skin problems (2.9) |
| 8       | Skin problems (2.9) | Headache and dizziness (2.9) |
| 9       | Diabetes mellitus (2.6) | Uterine and vaginal problems (2.0) |
| 10      | Dental problems (1.6) | Eye problems (1.6) |

Note: Results are shown for self-reported illnesses that occurred within 4 weeks prior to the baseline (3) and follow-up surveys. Multiple responses were recorded if more than one cause was provided.
visited a private clinic and 16.9% had used the district hospital of Bhaktapur. Another 14.2% visited teaching hospitals run by Nepal Medical College and Kathmandu Medical College in Kathmandu, and 5.4% visited local pharmacy shops for treatment.

The follow-up survey also assessed smoking behavior and alcohol consumption among people aged ≥18 years. Although overall smoking prevalence was similar (15% at baseline vs. 15.5% at follow-up, data not shown), smoking in males increased (20% at baseline vs. 23% at follow-up). Additionally, the follow-up survey showed that 12% of the people currently consume alcohol (15.5% male vs. 8.5% female).

Sociodemographic characteristics of women participating in the SBA study

Our study of SBA services included 434 women (median age 26 years) in the JD-HDSS who had delivered a baby within 2 years prior to the survey. Most (90.1%) were 20–34 years of age, and 5.8% were <20 years (Table 4). The predominant ethnicity was Brahmin/Chhetri (45.5%), followed by Newar (38.8%).

Although more than one in five women (21.7%) were illiterate, nearly one in four women (24.1%) had achieved intermediate-level education or above. About two-thirds (67.4%) were housewives, 15% worked in agriculture, and 7.2% worked in the service sector (Table 5).

Utilization of SBA

Almost all women (97.2%) had attended at least one antenatal care visit and 90.8% completed the adequate four or more visits (23). Utilization of institutional delivery service was 93.1%, and 13.2% of the women completed three postnatal care visits. Nearly three-fourths of respondents (73.8%) reported that their walking time to the nearest health facility was more than 30 min.

We used multivariate logistic regression analysis to assess the association of antenatal, delivery, and postnatal care services with background variables (Tables 6–8). Ethnicity was associated with adequate antenatal care visits, whereas other independent variables (i.e. education, wealth, and means of transport) were not significantly associated with such use. Newar and Brahmin/Chhetri women were 5.0 (95% CI: 2.06–12.28) and 5.7 times (95% CI: 2.22–14.83) more likely to access adequate antenatal care services compared to disadvantaged Janajati and Dalit women.

Adequacy of antenatal care visits (four or more visits) and use of transport were positively associated with institutional delivery. Women who received adequate antenatal care were 21 times more likely to use institutional delivery services. Women with access to transport (e.g. bus, taxi, or motorcycle) were 16.6 times more likely to use institutional delivery services.

Adequate postnatal care visits (24) were associated with occupation, wealth quintile, and ethnicity. Women who worked in the service sector were five times more likely to attend an adequate number of postnatal care visits compared to those who worked in agriculture. Women in the fourth and fifth wealth quintiles were seven times more likely to use postnatal care (24) services compared to women in the poorest quintile. Brahmin/Chhetri women were 0.34 times less likely to attend an adequate number of postnatal care (24) visits compared to disadvantaged Janajati and Dalit women.

Discussion

Our initial baseline in the JD-HDSS was conducted at the end of 2010 (3); the follow-up survey occurred at the end of 2012. The follow-up survey also introduced an assessment of women’s use of SBA services.

### Table 4. General characteristics of women participating in the study of utilization of skilled birth attendants at the Jhaukhel-Duwakot Health Demographic Surveillance Site (N = 434)

| Variables                        | N   | %   |
|----------------------------------|-----|-----|
| Age groups (years)               |     |     |
| <20                              | 25  | 5.8 |
| 20–24                            | 140 | 32.3|
| 25–29                            | 198 | 45.6|
| 30–34                            | 53  | 12.2|
| ≥35                              | 18  | 4.1 |
| Ethnicity                        |     |     |

Sociodemographic findings

The total population of the JD-HDSS increased 23.8% (13,669 in 2010 vs. 16,918 in 2012), largely due to increased in-migration. This rapidly growing and urbanizing area is moving toward an urban lifestyle (6), possibly explaining the increased level of in-migration. Nepal’s recent census shows that rural-to-urban migration is common, including in Bhaktapur, a predominantly urban district that received 31% in-migrants in 2001

Both surveys show the population structure of the JD-HDSS as a constrictive pyramid (Fig. 1). In Nepal’s national population pyramid, the population gradually increases in the age groups 0–4 years, 5–9 years, and 10–14 years; it then begins to decline in the 15–19-year-old age group (25). In contrast, the JD-HDSS population gradually increases up to the 25–29-year-old age group and starts to decline in the 30–34-year-old age group, revealing declining fertility and mortality rates in this peri-urban setting. Although the fertility rate is declining nationally, the crude birth rate is lower in the JD-HDSS (22 vs. 11.7 per 1,000, respectively) (25). The most recent national census (2011) showed lower fertility in urban areas (26). Our peri-urban JD-HDSS shows similar findings.

Mortality, morbidity, and health behaviors

Compared to the latest national census (2011), the crude death rate in JD-HDSS is about half of the national level (3.8 vs. 7.3 per 1,000 population, respectively) (25). Our surveys recorded no maternal and infant mortalities, possibly due to the high utilization of antenatal care, institutional delivery, and postnatal care services. In HDSS, maternal mortality is rare and, thus, difficult to determine in small sample sizes (27).

Increasing population, rapid urbanization, industrialization, migration, and changing lifestyles in Nepal have resulted in increased violence, injuries, and disabilities. Injuries account for about 8% of all deaths (28). Most accidents and injuries result from road-traffic accidents, interpersonal violence, poisoning, falls, and fires, and the highest proportion of road-traffic accidents occurs in the central region (28). In the JD-HDSS, the proportion of accidents and injuries has increased (2.9% at baseline vs. 6.5% at follow-up), possibly due to rapid urbanization and increasing population and in-migration.

Morbidity in the total population decreased (11.1% at baseline vs. 7.1% at follow-up) (Table 2), as did the proportion of non-communicable diseases (12% at baseline vs. 5.7% at follow-up). Although we conducted the survey during the same season of the year (October–December), increasing urbanization and health service availability and use could explain this decline in overall morbidity.

Studies on non-communicable diseases in various settings in Nepal report varying prevalence. A nationally

Antenatal care utilization (less than four times and four or more times).

Note: The association between antenatal care utilization and various independent variables is shown.

Table 5. Maternal health characteristics of women participating in the study of utilization of skilled birth attendant services at the Jhaukhel-Duwakot Health Demographic Surveillance Site

Table 6. Determinants of antenatal care service utilization at the Jhaukhel-Duwakot Health Demographic Surveillance Site, Bhaktapur, Nepal
representative hospital-based study reports that 31% of all admitted cases suffer from non-communicable diseases (29). In Eastern Nepal, the prevalence of coronary heart disease is 5.7% (30), whereas the national prevalence of hypertension in urban adults is 20% (31). Likewise, the prevalence of diabetes and impaired fasting glucose is 14.2 and 9.1%, respectively, in an urban population (32).

Others suggest that HDSS sites may have better health indicators compared to other populations because repeated data collection activities could function as a passive intervention (5). In the JD-HDSS, we have conducted other health-related research, including health camps, which might have contributed to reduced disease prevalence and increased awareness of health-related behaviors. The self-reported decrease in morbidity shown during follow-up should be interpreted cautiously because we measured the occurrence of illness by recall method, possibly introducing recall bias.

Tobacco-smoking behavior was unchanged at follow-up, although smoking among males increased (20% at baseline vs. 23% at follow-up). Smoking prevalence was lower in the JD-HDSS compared to other populations in Nepal, such as college students from Western Nepal (34.2%) (33) and males in Dharan Municipality (42.7%) (34). Similarly, alcohol consumption was more prevalent among males (15.5%) than females (8.5%). Nationally, 41% of the population used alcohol during the past year (48.3% male and 27.7% female) (35). Another study from Eastern Nepal reports that 16.6% of women aged 15 years consume alcohol (36).

Use of SBAs
We estimated the current use of antenatal, delivery, and postnatal care in the JD-HDSS and assessed the factors that influence such use. Antenatal care visits are an important platform for educating pregnant women and encouraging them to deliver their babies in a health facility. In managing pregnant women without evidence of pregnancy-related complications, medical conditions, or major health-related risk factors, the WHO recommends a minimum of four antenatal-care visits: 1) before 16 weeks, 2) at 24–28 weeks, 3) at 30–32 weeks, and 4) at 36–38 weeks (23). In the JD-HDSS, 90.8% of women attended at least four antenatal care visits, exceeding the

| Newar           | 0.44       | 0.18  | 1.08  | 0.073|
| Brahmin/Chhetri | 0.34       | 0.14  | 0.84  | 0.019|

Note: Results are shown for the association between postnatal care utilization and various independent variables.
of delivery care, but it is also difficult to determine (41). Increased distance from a health facility decreases the use of transport options in the rapidly urbanizing HDSS. Significant in our study, possibly due to increasing availability of distance with the use of delivery care was not significant in our study, possibly due to increasing availability of transport options in the rapidly urbanizing HDSS. Increased distance from a health facility decreases the use of delivery care, but it is also difficult to determine (41).

Our finding that access to transport strongly predicts the likelihood that women will seek delivery care concurs with our previous qualitative and quantitative studies in mid- and far-Western Nepal (15, 16) and a study in the rural Kavre District of Nepal (42). Studies from Afghanistan and Pakistan report that access to transport associates positively with the use of delivery care (43, 44).

Promotion of postnatal care services contributes importantly to maternal and neonatal health and reduces maternal and neonatal mortality (45). Nepal’s Ministry of Health recommends that women receive at least three postnatal checkups, the first within 24 h of delivery, the second on the third day following delivery, and the third on the seventh day following delivery (24). We determined that only about one in seven (13.2%) women completed the recommended three postnatal care visits within 7 days after delivery. Only one-fifth of women in a Western Nepal district accessed postnatal care from healthcare workers (46), suggesting lower utilization of such services compared to antenatal and delivery care. An Ethiopian study reports that only 2.9% of women completed three or more postnatal care visits, suggesting lack of time, long distance to a provider, and lack of guardians for childcare as reasons for low utilization of postnatal care services (47). Other reasons include believing that postnatal visits are not important unless mothers feel sick, women’s negative experiences with such care, and the belief that postnatal care is available only for babies (47).

Our study shows that occupation, wealth quintile, and ethnicity associate with adequate use of postnatal care services. Women working in the service sector were nearly five times more likely to receive adequate postnatal care than women engaged in agriculture. Women in the fourth and fifth (richest) wealth quintiles were seven times more likely to receive adequate postnatal care compared to those in the poorest quintile, concurring with studies from India and Bangladesh (17, 48).

Strengths and limitations

Since its establishment at the end of 2010, the JD-HDSS has provided an important sampling frame for various health research studies. Our follow-up study includes demographic and health parameters measured at baseline, thus facilitating comprehensive comparison. Additionally, we report data on women’s utilization of SBA services in this peri-urban setting of Nepal, whereas previous published studies focused mostly on rural areas.

Although established HDSS usually conduct annual update rounds (49), we conducted the second round update 2 years after the first survey. This factor might have limited the monitoring of demographic and health events in the JD-HDSS. Our morbidity data might exhibit bias because we based our measurement on participants’ recall of such events, affecting not only baseline but also follow-up measurements. Comparison with baseline was not possible for some health indicators (e.g. alcohol consumption, SBA use)
because they were introduced during the follow-up survey. Nevertheless, comparisons of these indicators will be possible in future follow-up surveys.

The relatively small number of women in the JD-HDSS who had delivered a baby during the prior two years may have influenced the strength of association between use of SBA services and background variables.

Conclusions
In the JD-HDSS, high in-migration has increased the total population and the number of households. Most health indicators in this peri-urban community exceed the national average. The major morbidity conditions continue to be respiratory diseases, fever, gastrointestinal problems, and bone and joint problems. Our follow-up survey showed an increasing proportion of accidents and injuries and a decreasing proportion of non-communicable diseases. Further investigation of reasons for the increased proportion of accidents and injuries is recommended for their timely prevention.

Most women (90%) accessed institutional delivery and received adequate antenatal care services, but only 13.2% received adequate postnatal care. Availability of transport and use of antenatal care services were associated positively with the use of institutional delivery services.

Authors' contributions
All authors participated in the design of the follow-up survey. BC designed and conducted the SBA study, analyzed data, searched the literature, and drafted the manuscript. BC, URA, BS, and AV conducted the follow-up survey. MP and URA provided advice on data analysis. AK, MP, and SO provided academic supervision and critical comments on the manuscript. All authors read and approved the final manuscript.

Acknowledgements
The authors thank all survey participants in the JD-HDSS. We also acknowledge the work of the field supervisors, enumerators, and staff of the VDCs. We thank Dr Muni Raj Chhetri for logistic management of enumerators' training and Khadga Shrestha for his help in data cleaning and translation of instruments. The authors thank scientific editor Karen Williams (Kwills Editing Services, Weymouth, MA, USA) for professional English-language editing of this article.

Conflict of interest and funding
The authors declare that they have no competing interests. The study received financial support from the University of Gothenburg through a Global University grant as well as grants from the Wilhelm and Martina Lundgren Foundation, Anna Ahrenberg Foundation, and Arvid & Karin Lundahl Foundation.
