Abstract
The theory of mean field games (MFGs) studies the limiting behaviors of large systems where the agents interact with each other in a certain symmetric way. The running and terminal costs are critical for the agents to decide the strategies. However, in practice they are often partially known or totally unknown for the agents, while the total cost is known at the end of the game. To address this challenging issue, we propose and study several inverse problems for MFGs. When the Lagrangian is a kinetic energy, we first establish unique identifiability results, showing that one can recover either the running cost or the terminal cost from knowledge of the total cost. If the running cost is limited to the time-independent class, we can further prove that one can simultaneously recover both the running and the terminal costs. Finally, we extend the results to the setup with general Lagrangians.

Keywords: mean field games, inverse problems, master equation, unique identifiability

1. Introduction
The theory of mean field games (MFGs) was introduced and studied by Huang et al [25–28] and Lasry and Lions [31–33, 36] independently in 2006. The MFG theory has rapidly developed into one of the most significant tools towards the study of the Nash equilibrium behavior of large systems. Such problems consider limit behavior of large systems where the homogeneous strategic players interact with each other in a certain symmetric way. More precisely, each player acts according to his/her optimization problem taking into account other players’ decisions. Since their population is large, we can assume the number of players goes to infinity and hence a representative player exists. They have a wide variety of applications, including economics [1], engineering [25], finance [30], social science [22] and many others.

∗ Author to whom any correspondence should be addressed.
We refer to Lions [36], Cardaliaguet [8] and Bensoussan et al [7] for introductions of the subject in its early stage and Carmona and Delarue [14, 15] and Cardaliaguet and Porretta [13] for comprehensive accounts on the state-of-the-art developments in the literature.

We first briefly introduce the mathematical setup of our study and shall supplement more details in section 2. In its typical formulation, an MFG can be interpreted as an optimisation problem in a probability space. Let $n \in \mathbb{N}$ and the quotient space $\mathbb{T}^n := \mathbb{R}^n \setminus \mathbb{Z}^n$ be the $n$-dimensional torus, which signifies a state space. Given $x \in \mathbb{T}^n$ and the flow of probability measures $\{\rho_t\}_{t \in [0,T]}$ on $\mathbb{T}^n$ with $\rho_0 = m_0$, one aims at minimizing the cost functional over all the admissible closed-loop controls:

$$J(x; \{\rho_t\}_{t \in [0,T]}, \alpha) = \inf_{\alpha} \mathbb{E} \left\{ \int_0^T L(X^t_{\xi^t,\alpha}, \alpha(t, X^t_{\xi^t,\alpha})) + F(X^t_{\xi^t,\alpha}, \rho_t) \, dt + G(X_T, \rho_T) \right\},$$  

such that

$$X^t_{\xi^t,\alpha} = x + \int_0^t \alpha(s, X^t_{\xi^t,\alpha}) \, ds + \sqrt{2} B_s + \mathbb{Z}^n \quad \text{on } [0,T],$$

where $L: \mathbb{T}^n \times \mathbb{R}^n \to \mathbb{R}$ is a Lagrangian, $F: \mathbb{T}^n \times \mathcal{P}(\mathbb{T}^n) \to \mathbb{R}$ is a running cost and $G: \mathbb{T}^n \times \mathcal{P}(\mathbb{T}^n) \to \mathbb{R}$ is a terminal cost. We call $\{\alpha^*, \{\rho^*_t\}_{t \in [0,T]}\}$ a mean field equilibrium (MFE) if

$$\rho^*_0 = m_0 \quad \text{and} \quad \alpha^* := \arg \min_{\alpha} J(x; \{\rho^*_t\}_{t \in [0,T]}, \alpha),$$

and the law of $X^t_{\xi^t,\alpha^*}$ on $\mathbb{T}^n$ is $\rho^*_t$ where

$$X^t_{\xi^t,\alpha^*} = \xi_0 + \int_0^t \alpha^*(s, X^t_{\xi^t,\alpha^*}) \, ds + \sqrt{2} B_s + \mathbb{Z}^n \quad \text{on } [0,T],$$

and its initial status $\xi_0$ is a random variable with the law $m_0$ on $\mathbb{T}^n$. From a PDE (Partial Differential equation) perspective, the MFE can be characterized by the following MFG system:

$$\begin{cases}
\partial_t u(x,t) - \Delta u(x,t) + H(x, \nabla u(x,t)) - F(x,t,m(x,t)) = 0, & (x,t) \in \mathbb{T}^n \times (0,T), \\
\partial_t m(x,t) - \Delta m(x,t) - \text{div}(m(x,t) \nabla p(x))^t) = 0, & (x,t) \in \mathbb{T}^n \times (0,T), \\
u(x,t) = G(x,m(x,t)), & m(x,0) = m_0(x),
\end{cases}$$

(1.4)

Our inverse problem study shall be mainly concerned with this coupled PDE system (1.4). In (1.4), $\Delta$ and div are the Laplacian and divergent operators with respect to the $x$-variable, respectively. The Hamiltonian $H$ is the Legendre–Fenchel transform of the Lagrangian $L$ in (1.1). Here, $H(x, \nabla u) = H(x,p)$ with $(x,p) := (x, \nabla u) \in \mathbb{T}^n \times \mathbb{R}^n$ being the canonical coordinates. In the physical setup, $u$ is the value function of each player; $m$ signifies the population distribution; $F$ is the running cost function which signifies the interaction between the agents and the population; $m_0$ represents the initial population distribution and $G$ signifies the terminal cost. All the functions involved are real valued and periodically extended from $\mathbb{T}^n$ to $\mathbb{R}^n$, which means that we are mainly concerned with periodic boundary conditions for the MFG system (1.4). In particular, we note that $m(\cdot, t)$ is required to be a probability measure for any $t \in [0,T]$. That is, it is required that for any given $t \in [0,T]$:

$$m(x,t) = m_t(x) \in \mathcal{O} := \left\{ m(x) : \mathbb{T}^n \to [0, \infty), \int_{\mathbb{T}^n} m \, dx = a \leq 1 \right\},$$

(1.5)

Here, we point out that by applying the divergence theorem to the second equation in (1.4), one can directly verify that if $\int_{\mathbb{T}^n} m_0(x) \, dx = a$, then $\int_{\mathbb{T}^n} m(x,t) \, dx = a$ for any subsequent $t \in (0,T]$. However, the non-negativity of $m_0$ and $m$ should be imposed in order to guarantee that they are
probability measures. In principle, one would also need to require that $a = 1$ which signifies that the game agents are confined within a given domain. Throughout the current study, we consider a specific scenario that the MFG domain consists of a family of disjoint subdomains, say $\Sigma_j, j \in \mathbb{N}$, such that the overall population on $\cup_j \Sigma_j$ is 1, namely $\int_{\cup_j \Sigma_j} m = 1$. Though those subdomains are disjoint, the agents within each subdomain can interact with those in other subdomains, say e.g. via internet. Hence if subdomains are disjoint, the agents within each subdomain can interact with those in other subdomains, say e.g. via internet. Hence if $\Sigma_j$, it is not necessary to require that $\int_{\Sigma_j} m = 1$. That is, $a$ in (1.5) can be any number in $[0, 1]$, as long as $m$ is required to be nonnegative. This technical relaxation is crucial in our subsequent study but practically unobjectionable. In this setup, the mean field strategy can be formally represented by $\alpha^* = - \nabla_p H(x, \nabla u(x, t))$. In section 2 in what follows, we shall supplement more background introduction on the MFG system.

The well-posedness of the MFG system (1.4) is well-understood in various settings. The first results date back to the original works of Lasry and Lions and have been presented in Lions [36] and see also Caines–Huang–Malhame [25]. Many progresses have been made afterwards. Regarding $F$ and $G$, one can consider both non-local and local dependences on the measure $m$. The well-posedness of the MFG system (1.4) is known in Cardaliaguet [8], Cardaliaguet and Porretta [13], Carmona and Delarue [14], Meszaros and Mou [37] in the case of nonlocal data $F$ and $G$; and Ambrose [2, 3], Cardaliaguet [9], Cardaliaguet-Graber [11], Cardaliaguet et al [12], Cardaliaguet and Porretta [13], Cirant et al [17], Cirant-Goffi [18], Ferreira and Gomez [20], Ferreira et al [21], Gomez et al [23, 24], Porretta [39] in the case that $F, G$ are locally dependent on the measure variable $m$.

We term the above well-posed MFG system (1.4) to be the forward problem. In this paper, we are mainly concerned with the inverse problem of determining the running cost $F$ or the terminal cost $G$ by knowledge of the total cost associated with the above MFG system. To that end, we introduce a measurement map $\mathcal{M}_{F,G}$ as follows:

$$\mathcal{M}_{F,G}(m_0(x)) = u(x, t)|_{t = 0}, \quad x \in \mathbb{T}^n,$$

(1.6)

where $m_0(x) \in O$ and $u(x, t)$ are given in the MFG system (1.4). That is, for a given pair of $F$ and $G$, $\mathcal{M}_{F,G}$ sends a prescribed initial population distribution $m_0$ to $u(x, 0)$, which signifies the total cost of the MFG (1.4). In section 3, we shall show that $\mathcal{M}_{F,G}$ is well-defined in proper function spaces. The inverse problem mentioned above can be formulated as:

$$\mathcal{M}_{F,G} \longrightarrow F \text{ or/and } G.$$  
(1.7)

In the MFG theory, the running cost $F$ and the terminal cost $G$ are critical for the agents to decide the strategies. However, in practice they are often partially known or totally unknown for the agents, while the total cost $u(\cdot, 0)$ can be measured at the end of the game. This is a major motivation for us to propose and study the inverse problem (1.7). We believe our study could have many applications in the areas mentioned above. An example in our mind is the product pricing. Suppose that in the market there are many companies are producing the same product for selling to make profits. As a customer, we do not have the information on the precise production cost, however we do know the selling price of the product at the end. Therefore, the recovery of the production cost is a typical inverse problem in the MFG.

In this paper, we are mainly concerned with the unique identifiability issue, which is of primary importance for a generic inverse problem. In its general formulation, the unique identifiability asks whether one can establish the following one-to-one correspondence:

$$\mathcal{M}_{F_1, G_1} = \mathcal{M}_{F_2, G_2} \text{ if and only if } (F_1, G_1) = (F_2, G_2),$$  
(1.8)

where $(F_j, G_j), j = 1, 2$, are two configurations.
Unlike the forward problem of MFGs, the theory of the inverse problem has not yet been well-established. To the best of our knowledge, only some numerical studies have been conducted to the inverse problem of MFGs. It starts from the recent work Ding–Li–Osher–Yin [19]. The authors reconstructed the running cost from the observation of the distribution of the population and the agents’ strategy. The running cost consists of a kinetic energy (with an unknown underlining metric) and a convolution-type running cost. The main goal there is to numerically recover the underlining metric and the convolution kernel. Another numerical work Chow–Fung–Liu–Nurbekyan–Osher [16] considered a different inverse problem of MFGs. The work focused on the recovery of the running cost from a finite number of the boundary measurements of the population profile and boundary movement. Both studies mentioned above consider the MFG model that the running cost is non-locally dependent on the measure variable, i.e. the MFG system are unique.

In our study of the inverse problem (1.7), we are mainly concerned with the data locally depending on the measure variable, i.e. \( F(x,t,m(\cdot,t)) := F(x,t,m(x,t)) \) and \( G(x,m(\cdot,T)) := G(x,m(x,T)). \) The model is motivated from the traffic flow and the crowd motion problems. For the problems, the cost depends only on the distribution of the population locally. We assume all the agents are rational and the observer only knows the total cost of agents at the end. The main goal is to recover the running or/and terminal costs. Let us briefly introduce the main results we prove in the paper. When the Lagrangian is a kinetic energy, we first show that the terminal cost \( G \) is uniquely identifiable by the measurement map \( M_{F,G} \) by assuming the running cost \( F \) is a-priori known. We emphasize that, for this inverse problem, we assume that the running and the terminal costs satisfy \( F(x,t,0) = G(x,0) = 0 \) and we justify that the assumption is necessary for both unique identifiability problems. Moreover, the running cost is allowed to be time-dependent. If the running cost is limited to the time-independent class, we further show that we can recover both the running and the terminal costs with the given measurement map \( M_{F,G} \). Finally, we extend a large extent of the above unique identifiability results to general Lagrangians. To establish those theoretical unique identifiability results, we develop novel mathematical strategies that make full use of the intrinsic structure of the MFG system. Our study opens up a new field of research on inverse problems for MFGs with many potential developments.

The rest of the paper is organized as follows. We introduce the admissibility assumptions on \( F \) and \( G \) and state the main results of this paper in section 2. In section 3, we establish certain well-posedness results of the forward MFG system, which shall be needed for the inverse problems. We discuss the admissibility assumptions in section 4. By counter examples, we show that those assumptions are unobjectionable for the inverse problems. Finally, we show various unique identifiability results in section 5 and some generalizations in section 6.

## 2. Preliminaries and statement of main results

### 2.1. Notations and basic setting

As introduced earlier, we let \( n \in \mathbb{N} \) and \( T^n := \mathbb{R}^n \setminus \mathbb{Z}^n \) be the \( n \)-dimensional torus. Set \( x = (x_1,x_2,\ldots,x_n) \in \mathbb{R}^n \). \( f(x) : x \in T^n \to \mathbb{R} \) is smooth and \( l = (l_1,l_2,\ldots,l_n) \in \mathbb{N}_0^n \) is a multi-index with \( \mathbb{N}_0 := \mathbb{N} \cup \{0\} \), then \( D^l f \) stands for the derivative \( \frac{\partial^{l_1}}{\partial x_1^{l_1}} \ldots \frac{\partial^{l_n}}{\partial x_n^{l_n}} f \). Given \( \nu \in \mathbb{S}^{n-1} := \{ x \in \mathbb{R}^n ; |x| = 1 \} \), we also denote by \( \partial_\nu f \) the directional derivative of \( f \) in the direction \( \nu \). For \( k \in \mathbb{N}_0 \),
and \( \alpha \in [0, 1) \), we say \( f \in C^{k+\alpha}(k \in \mathbb{N}_0) \) if \( D^l f \) exists and \( \alpha \)-Hölder continuous for any \( l \in \mathbb{N}_0^* \) with \( |l| \leq k \). Define
\[
C^{k+\alpha}_+(T^0) := \{ f(x) \in C^{k+\alpha}(T^0) : f(x) \geq 0 \}. \tag{2.1}
\]

It is remarked that the set \( C^{k+\alpha}_+(T^0) \) shall be needed in order to fulfill the probability measure constraint in our subsequent analysis; see also (1.5).

For functions \( f : T^0 \times (0, T) \rightarrow \mathbb{R} \), we say \( f \) belongs to \( C^{k+\alpha}_+(T^0) \) if \( D^l D^j f \) exists for any \( l \in \mathbb{N}_0^* \) and \( j \in \mathbb{N}_0 \) with \( |l| + 2j \leq k \) and
\[
\sup_{(x_1, t_1), (x_2, t_2) \in T^0 \times (0, T)} \frac{|D^l D^j f(x_1, t_1) - D^l D^j f(x_2, t_2)|}{|x_1 - x_2|^\alpha + |t_1 - t_2|} < \infty,
\]
for any \( l \in \mathbb{N}_0^* \) and \( j \in \mathbb{N}_0 \) with \( |l| + 2j = k \).

Throughout the paper, for a function \( f \) define on \( T^0 \) or \( T^0 \times (0, T) \), it means that it is a periodic-1 function with respect to the space variable \( x_j \), \( 1 \leq j \leq N \). That is, it is a periodic-(1, 1, \ldots, 1) function with respect to \( x \in \mathbb{R}^n \).

### 2.2. MFG

Let \( \mathcal{P}(T^0) \) and \( \mathcal{P}(\mathbb{R}^n) \) denote the set of probability measures on \( T^0 \) and \( \mathbb{R}^n \) respectively. Let \((\Omega, \mathcal{F}, \mathbb{P})\) be a filtered probability space; \( B \) be an \( \mathcal{F}\)-adapted Brownian motion on \( \mathbb{R}^n \); and we assume \( \mathcal{F}_0 \) is rich enough to support \( \mathcal{P}(T^0) \). For any \( \mathcal{F}\)-measurable random variable \( \xi \), we denote the law of \( \xi \) on \( \mathbb{R}^n \) by \( \mathcal{L}_\xi \in \mathcal{P}(\mathbb{R}^n) \) and the law of \( \xi \) on \( T^0 \) by \( \mathcal{L}_\xi_{\vert T^0} \in \mathcal{P}(T^0) \). Moreover, for any sub-\(\sigma\)-algebra \( \mathcal{G} \subset \mathcal{F} \) and any \( \rho \in \mathcal{P}(T^0) \), \( \mathcal{M}(\mathcal{G}; \rho) \) denotes the set of \( \mathcal{G}\)-measurable random variables \( \xi \) on \( \mathbb{R}^n \) such that \( \mathcal{L}_\xi_{\vert T^0} = \rho \).

Our MFG depends on the following data:
\[
L : T^0 \times \mathbb{R} \rightarrow \mathbb{R}, \quad F : T^0 \times \mathcal{P}(T^0) \rightarrow \mathbb{R} \quad \text{and} \quad G : T^0 \times \mathcal{P}(T^0) \rightarrow \mathbb{R}.
\]

Let \( T > 0 \). For any \( t_0 \in [0, T] \), we let \( \mathcal{A}_{t_0} \) denote the set of admissible \( \alpha : [t_0, T] \times T^0 \rightarrow \mathbb{R}^d \) which are Borel measurable, and uniformly Lipschitz continuous in \( x \). We also denote \( B^0_{t_0} := B_{t_0} - B_0 \), \( B^\alpha_{t_0} := B^\alpha_{t_0} - B^\alpha_0 \), \( t \in [t_0, T] \).

Given \( x \in T^0 \), \( \alpha \in \mathcal{A}_{t_0} \), and the flow of probability measures \( \{ \rho_t \}_{t \in [0, T]} \subset \mathcal{P}(T^0) \) with \( \rho_0 = m_0 \), the state of an agent satisfies the following controlled SDE (stochastic differential equation) on \([t_0, T] \):
\[
X^{b,\alpha}_{t_0, \alpha} = x + \int_{t_0}^t \alpha(s, X^{b,\alpha}_{s, \alpha}) ds + \sqrt{2} B^\alpha_s + \mathbb{Z}^n. \tag{2.2}
\]

Consider the conditionally expected cost for the MFG:
\[
J(t_0, x; \{ \rho_t \}_{t \in [0, T]}; \alpha) := \inf_{\alpha \in \mathcal{A}_{t_0}} \mathbb{E} \left[ \int_{t_0}^T L(X^{b,\alpha}_{t, \alpha}, \alpha(t, X^{b,\alpha}_{t, \alpha}), \rho_t) dt + G(X^{b,\alpha}_{T, \alpha}, \rho_T) \right]. \tag{2.3}
\]
Definition 2.1. We say that \((\alpha^*,\{\rho_t^*\}_{t\in[0,T]})\) is a MFE if it satisfies the following properties:

(i) \(\rho_0^* = \rho_0\);

(ii) for any \(\xi_0 \in \mathbb{M} (\mathcal{F}_0, \rho_0)\), we have \(\mathcal{L}_{\chi_t^{\xi_0,\alpha^*}} = \rho_t^*\) where
\[
\chi_t^{\xi_0,\alpha^*} = \xi_0 + \int_0^t \alpha^* (x, \chi_s^{\xi_0,\alpha^*}) ds + \sqrt{2}B_s + \mathbb{Z}^n;
\]

(iii) for any \((t_0, x) \in [0, T] \times \mathbb{T}^n\), we have
\[
J(t_0, x; \{\rho_t^*\}_{t\in[0,T]}, \alpha^*) = \inf_{\alpha \in \mathcal{A}_0} J(t_0, x; \{\rho_t^*\}_{t\in[0,T]}, \alpha), \quad \text{for } \rho_0^*\text{-a.e. } x \in \mathbb{T}^n.
\]

When there is a unique MFE \((\alpha^*,\{\rho_t^*\}_{t\in[0,T]})\), then the MFG leads to the following value function of the agent:
\[
u(t_0, x) := J(t_0, x; \{\rho_t^*\}_{t\in[0,T]}, \alpha^*)
\]

Let \(m(\cdot, t_0) = \rho_0^*\). Then \((u, m)\) solves the following MFG system (cf [13, 36]):
\[
\begin{align*}
-\partial_t u(x, t) - \Delta u(x, t) + \frac{1}{2} |\nabla u(x, t)|^2 &= F(x, t, m(x, t)), \quad \text{in } \mathbb{T}^n \times (0, T), \\
\partial_t m(x, t) - \Delta m(x, t) - \text{div}(m(x, t) \nabla u(x, t)) &= 0, \quad \text{in } \mathbb{T}^n \times (0, T), \\
u(x, T) = G(x, m(T, x)), \quad m(x, 0) &= m_0(x) \quad \text{in } \mathbb{T}^n,
\end{align*}
\]

where as mentioned earlier, periodic boundary conditions are imposed on \(\partial \mathbb{T}^n\) for \(u\) and \(m\).

2.3. Inverse problems

We recall the probability measure constraint \(\mathcal{O}\) introduced in (1.5). Define the set
\[
\mathcal{E}_{F,G} := \{\rho_0 \in C^{2+\alpha} (\mathbb{T}^n) \cap \mathcal{O} : \text{the system (2.4)}
\]

has a unique solution in the sense described in section 3 in what follows}.

We introduce the following measurement map \(\mathcal{M}_{F,G}\):
\[
\mathcal{M}_{F,G} : \mathcal{E}_{F,G} \to L^2(\mathbb{T}^n),
\]

\[
m_0 \mapsto \left( x \in \mathbb{T}^n \mapsto u(x, t) \bigg|_{t=0} \right),
\]

where \(u(x, t)\) is the solution of (2.4) with initial data \(m(x, 0) = m_0(x)\).

In the first setup of our study, we consider the case that \(F\) and \(G\) belong to an analytic class. Henceforth, we set
\[
Q = \overline{\mathbb{T}^n \times (0, T)},
\]

be the closure of \(\mathbb{T}^n \times (0, T)\).

Definition 2.2. We say \(U(x, t, z) : \mathbb{T}^n \times \mathbb{R} \times \mathbb{C} \to \mathbb{C}\) is admissible, denoted by \(U \in \mathcal{A}\), if it satisfies the following conditions:

(i) The map \(z \mapsto U(\cdot, \cdot, z)\) is holomorphic with value in \(C^{2+\alpha,1+\frac{\alpha}{2}}(Q)\) for some \(\alpha \in (0, 1)\);

(ii) \(U(x, t, 0) = 0\) for all \((x, t) \in \mathbb{T}^n \times (0, T)\).

Clearly, if (1) and (2) are fulfilled, then \(U\) can be expanded into a power series as follows:
\[
U(x, t, z) = \sum_{k=1}^{\infty} U^{(k)}(x,t) \frac{z^k}{k!},
\]

where \(U^{(k)}(x,t) = \frac{\partial^k U}{\partial z^k} (x, t, 0) \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q)\).
**Definition 2.3.** We say $U(x, z): \mathbb{T}^n \times \mathbb{C} \rightarrow \mathbb{C}$ is admissible, denoted by $U \in B$, if it satisfies the following conditions:

(i) The map $z \mapsto U(., z)$ is holomorphic with value in $C^{2+\alpha}(\mathbb{T}^n)$ for some $\alpha \in (0, 1)$;
(ii) $U(x, 0) = 0$ for all $x \in \mathbb{T}^n$.

Clearly, if (1) and (2) are fulfilled, then $U$ can be expanded into a power series as follows:

$$U(x, z) = \sum_{k=1}^{\infty} U^{(k)}(x) \frac{z^k}{k!},$$

(2.8)

where $U^{(k)}(x) = \frac{\partial^k U(x, 0)}{\partial z^k} \in C^{2+\alpha}(\mathbb{T}^n)$.

**Remark 2.1.** The admissibility conditions in definitions 2.2 and 2.3 shall be imposed as a-priori conditions on the unknowns $F$ and $G$ in what follows for our inverse problem study. It is remarked that as noted earlier that both $F$ and $G$ are functions of real variables. However, for technical reasons, we extend the functions to the complex plane with respect to the $z$-variable, namely $U(., z)$ and $U(., ., z)$, and assume that they are holomorphic as functions of the complex variable $z$. This also means that we shall assume $F$ and $G$ are restrictions of those holomorphic functions to the real line. This technical assumption shall be used to show the well-posedness of the MFG system in section 3. Throughout the paper, we also assume that in the series expansions (2.7) and (2.8), the coefficient functions $U^{(k)}$ are real-valued.

**Remark 2.2.** We would like to emphasise that the zero conditions, namely the admissibility conditions (ii) in definitions 2.2 and 2.3, are unobjectionable to our inverse problem study. In fact, in section 4 in what follows, we shall construct several MFG examples where the zero admissibility conditions are violated and the associated inverse problems have no unique identifiability results.

We are in a position to state the first unique recovery result for the inverse problem (1.7), which shows that one can recover the terminal cost $G$ from the measurement map $\mathcal{M}$. Here and also in what follows, we sometimes drop the dependence on $F, G$ of $\mathcal{M}$, and in particular in the case that one quantity is a-priori known, say $\mathcal{M}_F$ or $\mathcal{M}_G$, which should be clear from the context.

**Theorem 2.1.** Assume $F \in A$, $G_j \in B$ $(j = 1, 2)$. Let $\mathcal{M}_{G_j}$ be the measurement map associated to the following system:

$$
\begin{align*}
-\partial_t u(x, t) - \Delta u(x, t) + \frac{1}{2} |\nabla u(x, t)|^2 &= F(x, t, m(x, t)), & & \text{in } \mathbb{T}^n \times (0, T), \\
\partial_t m(x, t) - \Delta m(x, t) - \text{div} (m(x, t) \nabla u(x, t)) &= 0, & & \text{in } \mathbb{T}^n \times (0, T), \\
u(x, T) &= G_j(x, m(x, T)), & & \text{in } \mathbb{T}^n, \\
m(x, 0) &= m_0(x), & & \text{in } \mathbb{T}^n.
\end{align*}
$$

(2.9)

If for any $m_0 \in C^{2+\alpha}(\mathbb{T}^n) \cap \mathcal{O}$, one has

$$\mathcal{M}_{G_j}(m_0) = \mathcal{M}_{G_j}(m_0),$$

(2.10)

then it holds that

$$G_1(x, z) = G_2(x, z) \text{ in } \mathbb{T}^n \times \mathbb{R}.$$
population distribution in $\mathbb{T}^n$ with the total population $a$ being any number in $[0,1]$. In the practical setup, this means that in order to recover the terminal cost $G$ within $\mathbb{T}^n$, one needs to have observable data, namely $\mathcal{M}_G(m_0)$, from multiple games with different agent population distributions within the region $\mathbb{T}^n$. This is practically unobjectionable since as we discussed earlier in the introduction that $\mathbb{T}^n$ is treated as a sub-region of a game (with a game region containing $\mathbb{T}^n$ as its subset). This remark also applies to our subsequent results, especially theorem 2.2 in the following.

Notice that in theorem 2.1 we allow $F$ to depend on time. If we assume $F$ depends only on $x$ and $m(x,t)$, we can determine $F$ and $G$ simultaneously.

**Theorem 2.2.** Assume $F_j, G_j \in \mathcal{B}$ ($j = 1, 2$). Let $\mathcal{M}_{F_j, G_j}$ be the measurement map associated to the following system:

$$
\begin{align*}
-\partial_t u(x,t) - \Delta u(x,t) + \frac{1}{2} |\nabla u(x,t)|^2 &= F_j(x,m(x,t)), & \text{in } \mathbb{T}^n \times (0,T), \\
\partial_t m(x,t) - \Delta m(x,t) - \text{div}(m(x,t) \nabla u(x,t)) &= 0, & \text{in } \mathbb{T}^n \times (0,T), \\
u(x,T) &= G_j(x,m(x,T)), & \text{in } \mathbb{T}^n, \\
m(x,0) &= m_0(x), & \text{in } \mathbb{T}^n.
\end{align*}
$$

(2.11)

If for any $m_0 \in C^{2+\alpha}(\mathbb{T}^n) \cap \mathcal{O}$, one has

$$
\mathcal{M}_{F_1, G_1}(m_0) = \mathcal{M}_{F_2, G_2}(m_0),
$$

then it holds that

$$
(G_1(x,z), F_1(x,z)) = (G_2(x,z), F_2(x,z)) \text{ in } \mathbb{T}^n \times \mathbb{R}.
$$

In Theorems 2.1 and 2.2, the Lagrangian is of a quadratic form, namely $H(x, \nabla u)$ in (1.4) is of the form $\frac{1}{2} |\nabla u|^2$ (see (2.9)–(2.11)). In fact, we can extend a large extent of the results in those theorems to the case with a general Lagrangian. We choose to postpone the statement of those results in section 6 along with their proofs.

**3. Well-posedness of the forward problems**

In this section, we show the well-posedness of the MFG systems in our study. The key point is the infinite differentiability of the equation with respect to a given (small) input $m_0(x)$. As a preliminary, we recall the well-posedness result for linear parabolic equations [34] [10, Lemma 3.3].

**Lemma 3.1.** Consider the parabolic equation

$$
\begin{align*}
-\partial_t v(x,t) - \Delta v(x,t) + \text{div}(a(x,t) \cdot \nabla v(x,t)) &= f(x,t), & \text{in } \mathbb{T}^n \times (0,T), \\
v(x,0) &= v_0(x), & \text{in } \mathbb{T}^n.
\end{align*}
$$

(3.1)

where the periodic boundary condition is imposed on $v$. Suppose $a,f \in C^{\alpha, \frac{\alpha}{2}}(Q)$ and $v_0 \in C^{2+\alpha}(\mathbb{T}^n)$, then (3.1) has a unique classical solution $v \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q)$.

The following result is somewhat standard (especially theorem 3.1-(a)), while our technical conditions could be different from those in the literature. For completeness we provide a proof here. The idea is to differentiate the equation infinitely many times with respect to the (small) input $m_0(x)$. We recall that $Q$ is defined in (2.6) and periodic boundary conditions are imposed to the MFG systems. The following proof is based on the implicit functions theorem for Banach spaces. One may refer to [38] for more related details about the theory of maps between Banach spaces.
**Theorem 3.1.** Suppose that $F \in \mathcal{A}$ and $G \in \mathcal{B}$. The following results hold:

(a) There exist constants $\delta > 0$ and $C > 0$ such that for any

$$m_0 \in B_\delta(C^{2+\alpha}(\mathbb{T}^n)) := \left\{ m_0 \in C^{2+\alpha}(\mathbb{T}^n) : \|m_0\|_{C^{2+\alpha}(\mathbb{T}^n)} \leq \delta \right\},$$

the MFG system (2.4) has a solution $u \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q)$ which satisfies

$$\|(u,m)\|_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)} := \|u\|_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)} + \|m\|_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)} \leq C\|m_0\|_{C^{2+\alpha}(\mathbb{T}^n)}.$$  \hspace{1cm} (3.2)

Furthermore, the solution $(u, m)$ is unique within the class

$$\left\{(u, m) \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q) \times C^{2+\alpha,1+\frac{\alpha}{2}}(Q) : \|(u,m)\|_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)} \leq C\delta \right\}.$$  \hspace{1cm} (3.3)

(b) Define a function

$$S : B_\delta(C^{2+\alpha}(\mathbb{T}^n)) \to C^{2+\alpha,1+\frac{\alpha}{2}}(Q) \times C^{2+\alpha,1+\frac{\alpha}{2}}(Q)$$

by $S(m_0) := (u, v)$ where $(u, v)$ is the unique solution to the MFG system (2.4). Then for any $m_0 \in B_\delta(C^{2+\alpha}(\mathbb{T}^n))$, $S$ is holomorphic.

**Proof.** Let

$$X_1 := C^{2+\alpha}(\mathbb{T}^n),$$

$$X_2 := C^{2+\alpha,1+\frac{\alpha}{2}}(Q) \times C^{2+\alpha,1+\frac{\alpha}{2}}(Q),$$

$$X_3 := C^{2+\alpha}(\mathbb{T}^n) \times C^{2+\alpha}(\mathbb{T}^n) \times C^{2+\alpha,1+\frac{\alpha}{2}}(Q) \times C^{2+\alpha,1+\frac{\alpha}{2}}(Q),$$

and we define a map $\mathcal{K} : X_1 \times X_2 \to X_3$ by that for any $(m_0, \tilde{u}, \tilde{m}) \in X_1 \times X_2,$

$$\mathcal{K}(m_0, \tilde{u}, \tilde{m})(x,t) := (\tilde{u}(x,T) - G(x,\tilde{m}(x,T)), \tilde{m}(x,0) - m_0(x), -\partial_t \tilde{u}(x,t) - \Delta \tilde{u}(x,t) + \frac{|\nabla \tilde{u}(x,t)|^2}{2} - F(x,t,\tilde{m}(x,t), \partial_t \tilde{m}(x,t) - \Delta \tilde{m}(x,t) - \text{div}(\tilde{m}(x,t) \nabla \tilde{u}(x,t))).$$

First, we show that $\mathcal{K}$ is well-defined. Since the Hölder space is an algebra under the pointwise multiplication, we have $|\nabla u|^2, \text{div}(m(x,t)\nabla u(x,t)) \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q).$ By the Cauchy integral formula,

$$F^{(k)} \leq \frac{k!}{R^k} \sup_{|z|=R} \|F(\cdot, \cdot, z)\|_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)}, \quad R > 0. \hspace{1cm} (3.4)$$

Then there is $L > 0$ such that for all $k \in \mathbb{N},$

$$\left\| \frac{F^{(k)}}{k!} \right\|_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)} \leq \frac{L^k}{R^k} \|m\|_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)} \sup_{|z|=R} \|F(\cdot, \cdot, z)\|_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)}. \hspace{1cm} (3.5)$$

By choosing $R \in \mathbb{R}_+$ large enough and by virtue of (3.4) and (3.5), it can be seen that the series (2.7) converges in $C^{2+\alpha,1+\frac{\alpha}{2}}(Q)$ and therefore $F(x,m(x,t)) \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q).$ Similarly, we have $G(x,m(x,T)) \in C^{2+\alpha}(\mathbb{T}^n).$ This implies that $\mathcal{K}$ is well-defined.

Let us show that $\mathcal{K}$ is holomorphic. Since $\mathcal{K}$ is clearly locally bounded, it suffices to verify that it is weakly holomorphic; see [38, p 133 theorem 1]. That is we aim to show the map

$$\lambda \in \mathbb{C} \mapsto \mathcal{K}((m_0, \tilde{u}, \tilde{m}) + \lambda(m_0, \tilde{u}, \tilde{m})) \in X_3,$$

for any $(m_0, \tilde{u}, \tilde{m}) \in X_1 \times X_2$ is holomorphic. In fact, this follows from the condition that $F \in \mathcal{A}$ and $G \in \mathcal{B}.$
Note that $\mathcal{K}(0,0,0) = 0$. Let us compute $\nabla_{( \tilde{u}, \tilde{m} )} \mathcal{K}(0,0,0)$:

$$
\nabla_{( \tilde{u}, \tilde{m} )} \mathcal{K}(0,0,0)(u,m) = (u|_{t=T} - G^{(1)} m(x,T), m|_{t=0}, - \partial_t u(x,t) - \Delta u(x,t) - F^{(1)} m, \partial_t m(x,t) - \Delta m(x,t)).
$$

By lemma 3.1, if $\nabla_{( \tilde{u}, \tilde{m} )} \mathcal{K}(0,0,0) = 0$, we have $\tilde{m} = 0$ and then $\tilde{u} = 0$. Therefore, the map is injective.

On the other hand, letting $(r(x),s(x,t)) \in C^{2+\alpha}(\mathbb{T}^n) \times C^{\alpha,\frac{\alpha}{2}}(Q)$, and by lemma 3.1, there exists $a(x,t) \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q)$ such that

$$
\begin{align*}
\partial_t a(x,t) - \Delta a(x,t) &= s(x,t) \quad \text{in } \mathbb{T}^n, \\
a(x,0) &= r(x) \quad \text{in } \mathbb{T}^n.
\end{align*}
$$

Then letting $(r'(x),s'(x,t)) \in C^{2+\alpha}(\mathbb{T}^n) \times C^{\alpha,\frac{\alpha}{2}}(Q)$, one can show that there exists $b(x,t) \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q)$ such that

$$
\begin{align*}
-\partial_t b(x,t) - \Delta b(x,t) - F^{(1)} a &= s'(x,t) \quad \text{in } \mathbb{T}^n, \\
b(x,T) &= G^{(1)} a(x,T) + r'(x) \quad \text{in } \mathbb{T}^n.
\end{align*}
$$

Therefore, $\nabla_{( \tilde{u}, \tilde{m} )} \mathcal{K}(0,0,0)$ is a linear isomorphism between $X_2$ and $X_3$. Hence, by the implicit function theorem, there exist $\delta > 0$ and a unique holomorphic function $S : B_\delta(\mathbb{T}^n) \to X_2$ such that $\mathcal{K}(m_0, S(m_0)) = 0$ for all $m_0 \in B_\delta(\mathbb{T}^n)$.

By letting $(u,m) = S(m_0)$, we obtain the unique solution of the MFG system (2.4). Let $(u_0,v_0) = S(0)$. Since $S$ is Lipschitz, we know that there exist constants $C,C' > 0$ such that

$$
\| (u,m) \|_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)} \leq C \| m_0 \|_{B_\delta(\mathbb{T}^n)} + \| u_0 \|_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)} + \| v_0 \|_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)} \leq C \| m_0 \|_{B_\delta(\mathbb{T}^n)}.
$$

The proof is complete.

**Remark 3.1.** Regarding the local well-posedness, several remarks are in order.

(a) The conditions on $F$ and $G$ (definition 2.2-(i) and $G$ satisfies definition 2.3-(i)) are not essential and it is for convenience to apply implicit function theorem. Also, the analytic conditions on $F$ and $G$ can be replaced by weaker regularity conditions in the proof of the local well-posedness [36], but these conditions will be utilized in our inverse problem study.

(b) In order to apply the higher order linearization method that shall be developed in section 5 for the inverse problems, we need the infinite differentiability of the equation with respect to the given input $m_0(x)$, it is shown by the fact that the solution map $S$ is holomorphic.

(c) In the proof of theorem 3.1, we show the solution map $S$ is holomorphic. As a corollary, the measurement map $M = (\pi_1 \circ S)|_{t=0}$ is also holomorphic, where $\pi_1$ is the projection map with respect to the first variable.

4. Non-uniqueness and discussion on the zero admissibility conditions

In this section, we show that the zero admissibility conditions, namely $F(x,t,0) = 0$ and $G(x,0) = 0$ in definitions 2.2 and 2.3 are unobjectionably necessary if one intends to uniquely recover $F$ or $G$ by knowledge of the measurement operator $M_{F,G}$ for the inverse problem (1.7).
For simplicity, we only consider the case that the space dimension \( n = 1 \) without the periodic boundary conditions. That is, we consider the following MFG system:

\[
\begin{align*}
\partial_t u_1(x, t) - \partial_{xx} u_1(x, t) + \frac{1}{2} \left( \frac{\partial_x u_1(x, t)}{u_1(x, t)} \right)^2 &= F_1(x, t, v_1(x, t)), & \text{in } \mathbb{R} \times (0, T), \\
\partial_t v_1(x, t) - \partial_{xx} v_1(x, t) - \partial_t (v_1(x, t) \partial_t u_1(x, t)) &= 0, & \text{in } \mathbb{R} \times (0, T), \\
u_1(x, T) &= G_1(x, v_1(x, T)), & \text{in } \mathbb{R}, \\
u_1(x, 0) &= m_0(x), & \text{in } \mathbb{R}.
\end{align*}
\] (4.1)

Furthermore, we assume \( T \) is small enough such that the solution of the MFG system (4.1) is unique [2–4, 17, 36]. In what follows, we construct examples to show that if the zero admissibility conditions are violated then the corresponding inverse problems do not have uniqueness.

**Proposition 4.1.** Consider the system (4.1). There exist \( F_1 = F_2 \in C^\infty(\mathbb{R} \times \mathbb{R} \times \mathbb{R}) \) and \( G_1 \neq G_2 \in C^\infty(\mathbb{R} \times \mathbb{R}) \) (but we do not have \( G_1(x, 0) = G_2(x, 0) = 0 \)) such that the corresponding two systems admit the same measurement map, i.e. \( \mathcal{M}_{G_1} = \mathcal{M}_{G_2} \).

**Proof.** Set

\[ F_1 = F_2 = -\sin(x) + \frac{1}{4} (e^t - 1)^2 \cos^2(x), \]

and

\[ G_1 = (e^T - 1) \sin(x), \quad G_2 = (1 - e^T) \sin(x). \]

It can be directly verified that

\[ u_1(x, t) = (e^t - 1) \sin(x) \quad \text{and} \quad u_2(x, t) = (1 - e^t) \sin(x), \]

satisfy the corresponding system. In this case, we have \( \mathcal{M}_{G_1}(m_0) = \mathcal{M}_{G_2}(m_0) = 0 \) for any admissible \( m_0 \).

**Proposition 4.2.** Consider the system (4.1). There exist \( G_1 = G_2 \in C^\infty(\mathbb{R} \times \mathbb{R}) \) and \( F_1 \neq F_2 \in C^\infty(\mathbb{R} \times \mathbb{R} \times \mathbb{R}) \) (but we do not have \( F_j(x, t, 0) = 0, j = 1, 2 \)) such that the corresponding two systems admit the same measurement map, i.e. \( \mathcal{M}_{F_1, G_1} = \mathcal{M}_{F_2, G_2} \).

**Proof.** Set

\[ F_1 = -x(2t - T) + \frac{t^2(t - T)^2}{2}, \quad F_2 = -2x(2t - T) + 2t^2(t - T)^2, \]

and

\[ G_1 = G_2 = 0. \]

Here, it is noted that \( F_1 \) and \( F_2 \) are independent of \( v \). In such a case, it is straightforward to verify that \( u_j(x, t) = jx(t - T) \) is the solution of the corresponding system (4.1). Clearly, one has \( \mathcal{M}_{F_1}(m_0) = \mathcal{M}_{F_2}(m_0) = 0 \) for any admissible \( m_0 \).

Moreover, we can find \( F_1, F_2 \in C^\infty(\mathbb{R} \times \mathbb{R}) \) which are independent of \( t \) such that proposition 4.2 holds.

**Proof.** Define

\[ Lu_j := -\partial_t u(x, t) - \partial_{xx} u(x, t) + \frac{[\partial_t u]^2}{2}. \]

It is sufficient for us to show that there exist \( u_1(x, t), u_2(x, t) \) such that
(1) $Lu_1 \neq Lu_2$ and $\partial_t(Lu_j) = 0$ for $j = 1, 2$;
(2) $u_1(x, 0) = u_2(x, 0)$ and $u_1(x, T) = u_2(x, T)$.

In fact, if this is true, we can set $F_j = Lu_j$ and $G(x) = u_1(x, T)$. Then one has $G_1 = G_2$.

Without loss of generality, we assume $T = 1$. Let $p(t)$ be a non-zero solution of the following ordinary differential equation (ODE):

$$
(\ln(p'(t)))' = \frac{\sqrt{1 + 4t}}{2},
$$
and $q(t)$ be a solution of the ODE:

$$
\begin{cases}
2q'(t) + \sqrt{1 + 4t}q''(t) = p(t)p'(t)\sqrt{1 + 4t}, \\
q(0) = 0.
\end{cases}
$$

With $p(t)$ and $q(t)$ given above, we can set

$$
\begin{align*}
u_1(x, t) &= p(t(t - 1))x + q(t(t - 1)) \\
u_2(x, t) &= q(t(t - 1))x + 2q(t(t - 1)).
\end{align*}
$$

It can be directly verified that $u_1$ and $u_2$ fulfil the requirements (1) and (2) stated above. \(\Box\)

Finally, we would like to remark that by following a similar spirit, one may construct similar examples as those in propositions 4.1 and 4.2 to the MFG system (4.1) associated with a periodic boundary condition. However, this shall involve a bit more tedious calculations and is not the focus of the current study. We choose not to explore further. As also stated earlier, it is unobjectionable to see that the zero admissibility conditions are necessary for the inverse problem study.

5. Proofs of theorems 2.1 and 2.2

In this section, we present the proofs of the three main theorems, namely theorems 2.1 and 2.2. To that end, we first introduce a higher order linearization procedure associated with the MFG system (2.4) which shall be repeatedly used in the proofs. We also refer to [35] where a higher order linearization procedure was considered for a semi-linear parabolic equation.

Throughout the current section, if $f$ is a function defined on $\mathbb{T}^n$, we still use $f$ to denote the function obtained by extending $f$ to $\mathbb{R}^n$ periodically.

5.1. Higher-order linearization

This method depends on the infinite differentiability of the solution with respect to a given input $m_0(x)$, which was derived in theorem 3.1. In fact, Cardaliaguet, Delarue, Lasry and Lions developed this linearization method in some probability measure space; see [5]. However, the setup of our study is not completely covered by the discussion in [5] and for completeness and self-containedness, we show the process in what follows.

First, we introduce the basic setting of this higher order linearization method. Consider the system (2.4). Let

$$
m_0(x; \varepsilon) = \varepsilon \sum_{i=1}^N \varepsilon_{i f_i},
$$
where $f_i \in C^{2+\alpha}([0,T])$ and $\varepsilon = (\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_N) \in \mathbb{R}_+^N$ (where $\mathbb{R}_+ := \{ x \in \mathbb{R} : x \geq 0 \}$) with $|\varepsilon| = \sum_{i=1}^N |\varepsilon_i|$ small enough. Then $m_0 \in C^{2+\alpha}([0,T]) \cap \mathcal{O}$. By theorem 3.1, there exists a unique solution $(u(x,t;\varepsilon), m(x,t;\varepsilon))$ of (2.4). Let $(u(x,t;0), m(x,t;0))$ be the solution of (2.4) when $\varepsilon = 0$. Let

$$
\begin{align*}
    u^{(1)} := \partial_\varepsilon u|_{\varepsilon = 0} &= \lim_{\varepsilon \to 0} \frac{u(x,t;\varepsilon) - u(x,t;0)}{\varepsilon_1}, \\
m^{(1)} := \partial_\varepsilon m|_{\varepsilon = 0} &= \lim_{\varepsilon \to 0} \frac{m(x,t;\varepsilon) - m(x,t;0)}{\varepsilon_1}.
\end{align*}
$$

The idea is that we consider a new system of $(u^{(1)}, m^{(1)})$. If $F \in \mathcal{A}$, $g \in \mathcal{B}$, we have

$$(u(x,t;0), m(x,t;0)) = (0,0)$$

and hence

$$
\begin{align*}
    -\partial_t u^{(1)}(x,t) - \Delta u^{(1)}(x,t) &= \lim_{\varepsilon \to 0} \frac{1}{\varepsilon_1} \left[ \frac{\nabla u(x,t;\varepsilon)^2}{2} + \|\nabla u(x,t;\varepsilon)\|^2 \right] + F(x,t,m(x,t;\varepsilon)) - F(x,t,m(x,t;0)) \\
    &= \nabla u^{(1)} \cdot \left( \lim_{\varepsilon \to 0} \frac{\nabla u(x,t;\varepsilon) + \nabla u(x,t;0)}{2} \right) + \lim_{\varepsilon \to 0} \frac{1}{\varepsilon_1} \left[ F^{(1)}(x,t)(m(x,t;\varepsilon) - m(x,t;0)) \right] \\
    &= F^{(1)}(x,t)m^{(1)}(x,t).
\end{align*}
$$

Similarly, we can compute

$$
\begin{align*}
    \partial_t m^{(1)}(x,t) - \Delta m^{(1)}(x,t) &= \lim_{\varepsilon \to 0} \frac{1}{\varepsilon_1} \left[ \text{div}(m(x,t;\varepsilon)\nabla u(x,t;\varepsilon)) - m(x,t;0)\nabla u(x,t;0) \right] \\
    &= \lim_{\varepsilon \to 0} \frac{1}{\varepsilon_1} \left[ \text{div}(m(x,t;\varepsilon)\nabla u(x,t;\varepsilon) + m(x,t;\varepsilon)\Delta u(x,t;\varepsilon) \\
    - m(x,t;0)\nabla u(x,t;0) - m(x,t;0)\Delta u(x,t;0)) \right] \\
    &= 0.
\end{align*}
$$

Now, we have that $(u^{(1)}, m^{(1)})$ satisfies the following system:

$$
\begin{align*}
    \begin{cases}
    -\partial_t u^{(1)}(x,t) - \Delta u^{(1)}(x,t) = F^{(1)}(x,t)m^{(1)}(x,t), & \text{in } \mathbb{T}^n \times (0,T), \\
    \partial_t m^{(1)}(x,t) - \Delta m^{(1)}(x,t) = 0, & \text{in } \mathbb{T}^n \times (0,T), \\
    u^{(1)}(x,T) = G^{(1)}(x)m^{(1)}(x,T), & \text{in } \mathbb{T}^n, \\
    m^{(1)}(x,0) = f_1(x), & \text{in } \mathbb{T}^n.
    \end{cases}
\end{align*}
$$

(5.1)

Then we can define

$$
\begin{align*}
    u^{(0)} := \partial_\varepsilon u|_{\varepsilon = 0} &= \lim_{\varepsilon \to 0} \frac{u(x,t;\varepsilon) - u(x,t;0)}{\varepsilon_1}, \\
m^{(0)} := \partial_\varepsilon m|_{\varepsilon = 0} &= \lim_{\varepsilon \to 0} \frac{m(x,t;\varepsilon) - m(x,t;0)}{\varepsilon_1},
\end{align*}
$$

for all $I \in \mathbb{N}$ and obtain a sequence of similar systems. In the proof of theorem 2.1 in what follows, we recover the first Taylor coefficient of $F$ or $G$ by considering this new system (5.1). In order to recover the higher order Taylor coefficients, we consider

$$
\begin{align*}
    u^{(1,2)} := \partial_{\varepsilon_1} \partial_{\varepsilon_2} u|_{\varepsilon = 0}, m^{(1,2)} := \partial_{\varepsilon_1} \partial_{\varepsilon_2} m|_{\varepsilon = 0}.
\end{align*}
$$

(5.2)
By direct calculations, we have from (5.2) that
\[
-\partial u^{(1,2)}(x,t) - \Delta u^{(1,2)}(x,t) = -\nabla u^{(1)} \cdot \nabla u^{(2)} - \nabla u(x,t;0)
+ F^{(1)}_j m^{(1,2)} + F^{(2)}_j(x,t)m^{(1)}m^{(2)},
\]
and
\[
\partial m^{(1,2)}(x,t) - \Delta m^{(1,2)}(x,t)
= \partial_x \partial_{zz} \text{div}(m\nabla u)|_{\varepsilon=0}
= \nabla m(x,t;0)\nabla u^{(1)} + m^{(1,2)} \Delta u(x,t;0) + m(x,t;0) \Delta u^{(1,2)}
+ \text{div}(m^{(1)}\nabla u^{(2)}) + \text{div}(m^{(2)}\nabla u^{(1)})
= \text{div}(m^{(1)}\nabla u^{(2)}) + \text{div}(m^{(2)}\nabla u^{(1)}).
\]
Combining (5.3) and (5.4), we have the second order linearization as follows:
\[
\left\{
\begin{array}{l}
-\partial u^{(1,2)}(x,t) - \Delta u^{(1,2)}(x,t) + \nabla u^{(1)} \cdot \nabla u^{(2)}
= F^{(1)}(x,t)m^{(1,2)} + F^{(2)}(x,t)m^{(1)}m^{(2)}, \quad \text{in } \mathbb{T}^n \times (0,T), \\
\partial m^{(1,2)}(x,t) - \Delta m^{(1,2)} = \text{div}(m^{(1)}\nabla u^{(2)}) + \text{div}(m^{(2)}\nabla u^{(1)}), \quad \text{in } \mathbb{T}^n \times (0,T), \\
u^{(1,2)}(x,T) = G^{(1)}(x)m^{(1,2)}(x,T) + G^{(2)}(x)m^{(1)}m^{(2)}(x,T), \quad \text{in } \mathbb{T}^n, \\
m^{(1,2)}(x,0) = 0, \quad \text{in } \mathbb{T}^n.
\end{array}
\right.
\]
Notice that the non-linear terms of the system (5.5) depend on the first order linearized system (5.1). This shall be an important ingredient in the proof of theorem 2.1 in what follows.

Inductively, for $N \in \mathbb{N}$, we consider
\[
u^{(1,2,\ldots,N)} = \partial_{x_1}\partial_{x_2}\ldots\partial_{x_N}u|_{\varepsilon=0},
\]
\[
m^{(1,2,\ldots,N)} = \partial_{x_1}\partial_{x_2}\ldots\partial_{x_N}m|_{\varepsilon=0}.
\]
We can obtain a sequence of parabolic systems, which shall be employed again in determining the higher order Taylor coefficients of the unknowns $F$ and $G$.

5.2. Unique determination of single unknown function

We first present the proof of theorem 2.1.

**Proof of theorem 2.1.** Consider the following systems for $j = 1, 2$:
\[
\left\{
\begin{array}{l}
-\partial u_j(x,t) - \Delta u_j(x,t) + \frac{1}{2} \left| \nabla u_j \right|^2 = F(x,t,m_j(x,t)), \quad \text{in } \mathbb{T}^n \times (0,T), \\
\partial m_j(x,t) - \Delta m_j(x,t) = \text{div}(m_j(x,t)\nabla u_j(x,t)) = 0, \quad \text{in } \mathbb{T}^n \times (0,T), \\
u_j(x,T) = G_j(x,m_j(x,T)), \quad \text{in } \mathbb{T}^n, \\
m_j(x,0) = m_0(x), \quad \text{in } \mathbb{T}^n.
\end{array}
\right.
\]
By the successive linearization procedure, we first consider the case $N = 1$. Let
\[
u^{(1)} := \partial_{x_1}u_j|_{\varepsilon=0}, \quad m^{(1)} := \partial_{x_1}m_j|_{\varepsilon=0}.
\]
Direct computations show that \((u_j^{(1)}, v_j^{(1)})\) satisfies the following system

\[
\begin{cases}
-\partial_t u_j^{(1)}(x,t) - \Delta u_j^{(1)}(x,t) = F_j^{(1)}(x,t)m_j^{(1)}(x,t), & \text{in } \mathbb{T}^n \times (0, T), \\
\partial_t m_j^{(1)}(x,t) - \Delta m_j^{(1)}(x,t) = 0, & \text{in } \mathbb{T}^n \times (0, T), \\
u_j^{(1)}(x,T) = G_j^{(1)}(x)m_j^{(1)}(x,T), & \text{in } \mathbb{T}^n, \\
m_j^{(1)}(x,0) = f_1(x), & \text{in } \mathbb{T}^n.
\end{cases}
\]  
(5.7)

We can solve the system (5.7) by first deriving \(m_j^{(1)}\) and then obtaining \(u_j^{(1)}\). In doing so, we can obtain that the solution is

\[
m_j^{(1)}(x,t) = \int_{\mathbb{R}^n} \Phi(x - y, t)f_1(y) \, dy,
\]

\[
u_j^{(1)}(x,t) = \int_{\mathbb{R}^n} \Phi(x - y, T - t)G_j^{(1)}(y)m_j^{(1)}(y,T) \, dy
\]

\[+ \int_0^{T-t} \int_{\mathbb{R}^n} \Phi(x - y, T - t - s)F_j^{(1)}(y,T-s)m_j^{(1)}(y,s) \, dy \, ds,
\]

where \(m_j^{(1)}(x,t) = m_j^{(1)}(x,T-t)\) and \(\Phi\) is the fundamental solution of the heat equation:

\[
\Phi(x,t) = \frac{1}{(4\pi t)^{n/2}} e^{-\frac{|x|^2}{4t}}.
\]  
(5.8)

Since \(\mathcal{M}_G = \mathcal{M}_{G_1}\), we have

\[
u_1^{(1)}(x,0) = u_2^{(1)}(x,0),
\]

for all \(f_1 \in C^{2+\alpha}_c(\mathbb{T}^n)\). This implies that

\[
\int_{\mathbb{R}^n} \Phi(x - y, T) \left[ G_1^{(1)}(y)m_1^{(1)}(y,T) - G_2^{(1)}(y)m_2^{(1)}(y,T) \right] \, dy = 0.
\]

Noticing that \(m_1^{(1)}(x,t) = m_2^{(1)}(x,t)\), we choose

\[
m_1^{(1)}(x,T) = m_2^{(1)}(x,T) = \exp(-4\pi^2|\xi|^2 T - 2\pi i \xi \cdot x) + M,
\]

where \(\xi \in \mathbb{Z}^n, M \in \mathbb{N}\). (In this case, \(f_1(x) \in C^{2+\alpha}_c(\mathbb{T}^n)\))

By taking \(M_1 = 1\) and \(M_2 = 2\), respectively and then subtracting the resulting equations from one another, one can readily show that

\[
\int_{\mathbb{R}^n} \Phi(x - y, T) \left[ (G_1^{(1)}(y) - G_2^{(1)}(y)) \exp(-2\pi i \xi \cdot y) \right] \, dy = 0,
\]  
(5.9)

for all \(\xi \in \mathbb{Z}^n\). Therefore \(G_1^{(1)}(x) = G_2^{(1)}(x)\).

We proceed to consider the case \(N = 2\). Let

\[
u_j^{(1,2)} := \partial_{x_1} \partial_{x_2} u_j|_{\epsilon = 0}, \quad m_j^{(1,2)} := \partial_{x_1} \partial_{x_2} m_j|_{\epsilon = 0},
\]

and

\[
u_j^{(2)} := \partial_{x_2} u_j|_{\epsilon = 0}, \quad m_j^{(2)} := \partial_{x_2} m_j|_{\epsilon = 0}.
\]
Then we can deal with the second-order linearization:

\[
\begin{cases}
-\partial_{tt} u_j^{(1,2)}(x,t) - \Delta u_j^{(1,2)}(x,t) + \nabla u_j^{(1)} \cdot \nabla u_j^{(2)} = F^{(1)} m_j^{(1,2)} + F^{(2)} (x,t) m_j^{(1)} m_j^{(2)}, & \text{in } \mathbb{T}^n \times (0, T), \\
\partial_t m_j^{(1,2)}(x,t) - \Delta m_j^{(1,2)}(x,t) = \text{div}(m_j^{(1)} \nabla u_j^{(2)}) + \text{div}(m_j^{(2)} \nabla u_j^{(1)}), & \text{in } \mathbb{T}^n \times (0, T), \\
u_j^{(1,2)}(x,T) = G_j^{(1)}(x)m_j^{(1,2)}(x,T) + G_j^{(2)}(x)m_j^{(1)}(x,T), & \text{in } \mathbb{T}^n, \\
m_j^{(1,2)}(x,0) = 0, & \text{in } \mathbb{T}^n.
\end{cases} \tag{5.10}
\]

Since we have shown that $G_1^{(1)}(x) = G_2^{(1)}(x)$, we have

\[u_1^{(1)}(x,t) = u_2^{(1)}(x,t), \quad m_1^{(1)}(x,t) = m_2^{(1)}(x,t)\]

by solving equation (5.7).

Then by the same argument in the case $N = 1$ (considering $m_0 = \varepsilon f_2$), we have

\[u_1^{(2)}(x,t) = u_2^{(2)}(x,t), \quad m_1^{(2)}(x,t) = m_2^{(2)}(x,t).\]

Denote

\[p(x,t) = \text{div}(m_j^{(1)} \nabla u_j^{(2)}) + \text{div}(m_j^{(2)} \nabla u_j^{(1)}), \quad q(x,t) = -\nabla u_j^{(1)} \cdot \nabla u_j^{(2)}.\]

Then we can also solve system (5.10) as follows:

\[m_j^{(1,2)}(x,t) = \int_0^t \int_{\mathbb{R}^n} \Phi(x - y, t - s) p(y,s) \, dy \, ds, \]

\[u_j^{(1,2)}(x,t) = \int_{\mathbb{R}^n} \Phi(x - y, T - t) \left[ G_j^{(1)}(x)m_j^{(1,2)}(x,T) + G_j^{(2)}(x)m_j^{(1)}m_j^{(2)}(x,T) \right] \, dy \\
+ \int_0^{T-t} \int_{\mathbb{R}^n} \Phi(x - y, T - t - s) \left( F^{(2)}(y, T - s)m_j^{(1)}m_j^{(2)}(y, T - s) - \mathbf{q}(y,s) \right) \, dy \, ds,
\]

where $\mathbf{q}(y,s) = q(y, T - s)$. Since

\[u_1^{(1,2)}(x,0) = u_2^{(1,2)}(x,0),\]

we have

\[\int_{\mathbb{R}^n} \Phi(x - y, T) \left[ G_1^{(2)}(y)m_1^{(1)}(y,T) - G_2^{(2)}(y)m_2^{(1)}(y,T) \right] \, dy = 0.\]

Next, by a similar argument in the case $N = 1$, we can prove that $G_1^{(2)}(x) = G_2^{(2)}(x)$. Finally, by the mathematical induction, we can show the same result for $N \geq 3$. That is, for any $k \in \mathbb{N}$, we have $G_1^{(k)}(x) = G_2^{(k)}(x)$. The proof is complete. \(\square\)
5.3. Simultaneous recovery results for inverse problems

In this section, we aim to determine $F$ and $G$ simultaneously. To that end, we first derive an auxiliary lemma as follows.

**Lemma 5.1.** Let $u$ be a solution of the heat equation
\[
\begin{align*}
&\frac{\partial u(x,t) - \Delta u(x,t)}{\partial t} = 0 \quad \text{in } \mathbb{T}^n \times (0, T), \\
&u(x,0) = u_0(x) \quad \text{in } \mathbb{T}^n.
\end{align*}
\]  
(5.11)

Let $f(x) \in C^{2+\alpha}({\mathbb{T}}^n)$ for some $\alpha \in (0, 1)$. Suppose
\[
\int_{\mathbb{T}^n \times (0,T)} f(x)u(x,t)\,dxdt = 0,
\]  
(5.12)

for all $u_0 \in C^\infty_c(\mathbb{T}^n)$. Then one has $f = 0$.

**Proof.** Let $\xi \in \mathbb{Z}^n$ and $M \in \mathbb{N}$. It is directly verified that
\[
u(x,t) = \exp(-2\pi i \xi \cdot x - 4\pi^2 |\xi|^2 t) + M, \quad i := \sqrt{-1},
\]  
is a solution of (5.11) with initial value
\[
u_0(x) = \exp(-2\pi i \xi \cdot x) + M \geq 0.
\]

Then (5.12) implies that
\[
\int_{\mathbb{T}^n} \frac{1 - \exp(-4\pi^2 |\xi|^2 T)}{4\pi^2 |\xi|^2} f(x)e^{-2\pi i \xi \cdot x}\,dx + MT \int_{\mathbb{T}^n} f(x)\,dx = 0.
\]

By taking $M = 1$ and $M = 2$, respectively, we have
\[
\int_{\mathbb{T}^n} f(x)e^{-2\pi i \xi \cdot x}\,dx = 0.
\]

Hence, the Fourier series of $f(x)$ is 0. Since $f(x) \in C^{2+\alpha}({\mathbb{T}}^n)$, its Fourier series converges to $f(x)$ uniformly. Therefore, $f(x) = 0$. \qed

We are now in a position to present the proof of theorem 2.2.

**Proof of theorem 2.2.** Consider the following systems
\[
\begin{align*}
&-\partial_t u_j(x,t) - \Delta u_j(x,t) + \frac{1}{2} |\nabla u_j|^2 = F_j(x,m_j(x,t)), \quad \text{in } \mathbb{T}^n \times (0, T), \\
&\partial_t m_j(x,t) - \Delta m_j(x,t) - \text{div}(m_j(x,t)\nabla u_j(x,t)) = 0, \quad \text{in } \mathbb{T}^n \times (0, T), \\
&u_j(x,T) = G_j(x,m_j(x,T)), \quad \text{in } \mathbb{T}^n, \\
&m_j(x,0) = m_0(x), \quad \text{in } \mathbb{T}^n.
\end{align*}
\]  
(5.13)

Following a similar method we used in the proof of theorem 2.1, we let
\[
m_0(x; \varepsilon) = \sum_{i=1}^N \varepsilon f_i,
\]

where $f_i \in C^{2+\alpha}({\mathbb{T}}^n)$ and $\varepsilon = (\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_N) \in \mathbb{R}_+^N$ with $|\varepsilon| = \sum_{i=1}^N |\varepsilon_i|$ small enough.

Consider the case $N = 1$. Let
\[
\begin{align*}
u_j^{(1)} := & \partial_{x_i} u_j |_{\varepsilon=0}, \\
m_j^{(1)} := & \partial_{x_i} m_j |_{\varepsilon=0}.
\end{align*}
\]

17
Then direct computations imply that \((u_j^{(1)}, v_j^{(1)})\) satisfies the following system:

\[
\begin{align*}
-\partial u_j^{(1)}(x,t) - \Delta u_j^{(1)}(x,t) &= F_j^{(1)}(x)m_j^{(1)}(x,t), \quad \text{in } \mathbb{T}^n \times (0,T), \\
\partial m_j^{(1)}(x,t) - \Delta m_j^{(1)}(x,t) &= 0, \quad \text{in } \mathbb{T}^n \times (0,T), \\
u_j^{(1)}(x,T) &= G_j^{(1)}(x)m_j^{(1)}(x,T), \quad \text{in } \mathbb{T}^n, \\
m_j^{(1)}(x,0) &= f_j(x), \quad \text{in } \mathbb{T}^n.
\end{align*}
\] (5.14)

Then we have \(m_1^{(1)} = m_2^{(1)} := m^{(1)}(x,t)\). Let \(\pi = u_1^{(1)} - u_2^{(1)}\), (5.14) implies that

\[
\begin{align*}
-\partial \pi - \Delta \pi &= (F_1^{(1)} - F_2^{(1)})m^{(1)}(x,t), \\
\pi(x,T) &= (G_1^{(1)} - G_2^{(1)})m^{(1)}(x,T).
\end{align*}
\] (5.15)

Now let \(w\) be a solution to the heat equation \(\partial_t w(x,t) - \Delta w(x,t) = 0\) in \(\mathbb{T}^n\). Then

\[
\int_Q (F_1^{(1)} - F_2^{(1)})m^{(1)}(x,t)w(x,t) \, dx \, dt = \int_Q (-\partial \pi - \Delta \pi)w \, dx \, dt = \int_{\mathbb{T}^n} (\pi w)_T^0 \, dx + \int_Q \pi \partial_t w - \pi \Delta w
\]

\[
= \int_{\mathbb{T}^n} (\pi w)_T^0 \, dx. \tag{5.16}
\]

Since \(M_{F_1, G_1} = M_{F_2, G_2}\), we have

\[
\pi(x,0) = 0.
\]

It follows that

\[
\int_Q (F_1^{(1)} - F_2^{(1)})m^{(1)}(x,t)w(x,t) \, dx \, dt = \int_{\mathbb{T}^n} w(x,T)(G_1^{(1)} - G_2^{(1)})m^{(1)}(x,T) \, dx, \tag{5.17}
\]

for all solutions \(w(x,t), m^{(1)}(x,t)\) of the heat equation in \(\mathbb{T}^n\).

Here, we cannot apply lemma 5.1 directly. Nevertheless, we use the same construction. Let \(\xi_1, \xi_2 \in \mathbb{Z}^n \setminus \{0\}, M \in \mathbb{N}^+\) and \(\xi = \xi_1 + \xi_2\). Let

\[
w(x,t) = \exp(-2\pi i \xi_1 \cdot x - 4\pi^2 |\xi_1|^2 t),
\]

and

\[
m(x,t) = \exp(-2\pi i \xi_2 \cdot x - 4\pi^2 |\xi_2|^2 t) + M.
\]

Then the left hand side of (5.17) is

\[
\frac{1}{4\pi^2 (|\xi_1|^2 + |\xi_2|^2)} \int_{\mathbb{T}^n} (F_1^{(1)} - F_2^{(1)})e^{-2\pi i \xi \cdot x} \, dx + M \frac{1}{4\pi^2 |\xi_1|^2} \int_{\mathbb{T}^n} (F_1^{(1)} - F_2^{(1)})e^{-2\pi i \xi_1 \cdot x} \, dx. \tag{5.18}
\]
And the right hand side is
\[
\int_{\mathbb{T}} \exp(-4\pi^2 T(|\xi_1|^2 + |\xi_2|^2))(G_1^{(1)} - G_2^{(1)})e^{-2\pi i \xi \cdot x} \, dx
\]
\[
+ M \exp(-4\pi^2 T|\xi_1|^2) \int_{\mathbb{T}} (G_1^{(1)} - G_2^{(1)})e^{-2\pi i \xi \cdot x} \, dx.
\]  \tag{5.19}

By taking \( M = 1 \) and \( M = 2 \), respectively and then subtracting the resulting equations from one another, one can readily show that
\[
\frac{1 - \exp(-4\pi^2 T|\xi_1|^2)}{4\pi^2 (|\xi_1|^2 + |\xi_2|^2)} \int_{\mathbb{T}} (F_1^{(1)} - F_2^{(1)})e^{-2\pi i \xi \cdot x} \, dx = \exp(-4\pi^2 T|\xi_1|^2)
\]
\[
\times \int_{\mathbb{T}} (G_1^{(1)} - G_2^{(1)})e^{-2\pi i \xi \cdot x} \, dx.
\]

Then (5.17)–(5.19) readily yields that
\[
\frac{1 - \exp(-4\pi^2 T|\xi_1|^2 + |\xi_2|^2))}{4\pi^2 (|\xi_1|^2 + |\xi_2|^2)} a_\xi + \exp(-4\pi^2 T(|\xi_1|^2 + |\xi_2|^2)) b_\xi = 0.
\]

For a given \( \xi \in \mathbb{Z}^n \), there exist \( \xi_1, \xi_2, \xi_1', \xi_2' \in \mathbb{Z}^n \setminus \{0\} \) such that \( \xi = \xi_1 + \xi_2 = \xi_1' + \xi_2' \) and \( |\xi_1|^2 + |\xi_2|^2 \neq |\xi_1'|^2 + |\xi_2'|^2 \). Therefore, \( a_\xi = b_\xi = 0 \) for all \( \xi \in \mathbb{Z}^n \). Notice that it follows that \( F_1^{(1)} - F_2^{(1)} = G_1^{(1)} - G_2^{(1)} = 0 \).

Next, we consider the case \( N = 2 \). Let
\[
u_j^{1,2} := \partial_{x_1}\partial_{x_2}u_j|_{\varepsilon = 0}, \quad m_j^{1,2} := \partial_{x_1}\partial_{x_2}m_j|_{\varepsilon = 0},
\]
and
\[
u_j^{2} := \partial_{x_2}\nu_j|_{\varepsilon = 0}, \quad m_j^{2} := \partial_{x_2}m_j|_{\varepsilon = 0}.
\]  \tag{5.20}

By the second-order linearization in (5.20) and (5.21), we can obtain
\[
\begin{cases}
-\partial_t u_j^{1,2}(x,t) - \Delta u_j^{1,2}(x,t) + \nabla u_j^{1,2} \cdot \nabla u_j^{1,2} = F_j^{(1)} m_j^{1,2} + F_j^{(2)} (x)m_j^{(1)} m_j^{(2)}, & \text{in } \mathbb{T}^n \times (0,T), \\
\partial_t m_j^{1,2}(x,t) - \Delta m_j^{1,2}(x,t) = \text{div}(m_j^{(1)} \nabla u_j^{1,2}) + \text{div}(m_j^{(2)} \nabla u_j^{1,2}), & \text{in } \mathbb{T}^n \times (0,T), \\
u_j^{1,2}(x,T) = G_1^{(1)}(x)m_j^{1,2}(x,T) + G_2^{(2)}(x)m_j^{(1)} m_j^{(2)}(x,T), & \text{in } \mathbb{T}^n, \\
m_j^{1,2}(x,0) = 0, & \text{in } \mathbb{T}^n.
\end{cases}
\]  \tag{5.22}

By following a similar argument in the case \( N = 1 \), we have
\[
u_1^{1}(x,t) = u_2^{1}(x,t), u_1^{2}(x,t) = u_2^{2}(x,t),
\]
and
\[
m_1^{1}(x,t) = m_2^{1}(x,t), m_1^{2}(x,t) = m_2^{2}(x,t).
\]

Let \( \tilde{u}(x,t) = \nu_1^{1,2}(x,t) - u_2^{1,2}(x,t) \). We have
\[
\begin{cases}
-\partial_t \tilde{u} - \Delta \tilde{u} = (F_1^{(1)} - F_2^{(1)}) m_1^{1}(x,t) m_2^{2}(x,t), \\
\tilde{u}(x,T) = (G_1^{(1)} - G_2^{(1)}) m_1^{1}(x,T) m_2^{2}(x,t).
\end{cases}
\]  \tag{5.23}
Let $w$ be a solution of the heat equation $\partial_tw(x,t)-\Delta w(x,t)=0$ in $\mathbb{T}^n$. Then by following a similar argument in the case $N=1$, we can show that
\begin{equation}
\int_Q (F^{(2)}_1-F^{(2)}_2)\left(m^{(1)}_1\partial_1 m^{(2)}_1\right)w(x,t)dxdt
=\int_{\mathbb{T}^n}w(x,T)(G_1^{(2)}-G_2^{(2)})m^{(1)}(x,T)m^{(2)}_1(x,T)dx.
\end{equation}
(5.24)
To proceed further, by using the construction in lemma 5.1 again, we have from (5.24) that
\[ F_1^{(2)}-F_2^{(2)}=G_1^{(2)}-G_2^{(2)}=0. \]
Finally, via a mathematical induction, we can derive the same result for $N \geq 3$. That is, for any $k \in \mathbb{N}$, we have
\[ F_1^{(k)}(x)-F_2^{(k)}(x)=G_1^{(k)}(x)-G_2^{(k)}(x)=0. \]
Hence,
\[ (F_1(x,z),F_2(x,z)) = (G_1(x,z),G_2(x,z)), \text{ in } \mathbb{R}^n \times \mathbb{R}. \]
The proof is complete. \hfill \Box

**Remark 5.1.** Theorem 2.2 is not strictly stronger than theorem 2.1. We need $F(x,z)$ is independent of $t$ in the proof of theorem 2.2 but we do not need this condition in the proof of theorem 2.1.

**Remark 5.2.** In the proof of theorem 2.2, we arrived at a decoupled system after applying the linearization technique. However, we cannot simply apply existing results in inverse problems for a single parabolic equation. In fact, for a single parabolic equation, it is impossible to determine the source term $f$ by the corresponding boundary measurement. For a simple illustration, we let $h(x) \in C^0_0(Q)$, and consider the following two parabolic equations for a given $f \in C(Q),
\begin{align*}
\partial_t u - \Delta u &= f \quad \text{and} \quad \partial_t \tilde{u} - \Delta \tilde{u} = \tilde{f} , \quad \tilde{f} := f + (\partial_t h - \Delta h).
\end{align*}
It can be directly verified that $u$ and $\tilde{u}$ possess the same boundary data, though $f \equiv \tilde{f}$ in general. Hence, the proof of theorem 2.1 makes advantageous use on the peculiar structures of the MFG system. The same fact holds for the proofs of theorems 6.1 and 6.2 in what follows.

6. Inverse problems for MFGs with general Lagrangians

In the previous sections, we established the unique identifiability results for the inverse problems by assuming that the Hamiltonian involved is of a quadratic form, which represents a kinetic energy. In this section, we show that one can extend a large part of the previous results to the case with general Lagrangians if $F$ is independent of $t$.

In what follows, we let $T>0$ and $n \in \mathbb{N}$ and consider the following system of nonlinear PDEs:
\begin{align*}
-\partial_t u(x,t) - \Delta u(x,t) + H(x,\nabla u) &= F(x,m(x,t)), \quad \text{in } \mathbb{T}^n \times (0,T), \\
\partial_t m(x,t) - \Delta m(x,t) - \text{div}(m(x,t)H_p(x,\nabla u)) &= 0, \quad \text{in } \mathbb{T}^n \times (0,T), \\
u(x,T) &= G(x,m_T), \quad \text{in } \mathbb{T}^n, \\
m(x,0) &= m_0(x), \quad \text{in } \mathbb{T}^n.
\end{align*}
(6.1)
We study the inverse problem (1.7) and (1.8) associated with (6.1). In order to apply the method developed in the previous sections to this general case, we first introduce a new analytic class.

**Definition 6.1.** Let $H(x, z_1, z_2, \ldots, z_n)$ be a function mapping from $\mathbb{R} \times \mathbb{C}^n$ to $\mathbb{C}$. We say that $H$ is admissible and write $H \in \mathcal{I}$ if it fulfills the following conditions:

1. The map $(z_1, z_2, \ldots, z_n) \rightarrow H('z_1, z_2, \ldots, z_n)$ is holomorphic with value in $C^{2+\alpha}(\mathbb{T}^n)$, $\alpha \in (0, 1)$;
2. $H(x, 0) = 0$, for all $x \in \mathbb{T}^n$.

It is clear that $H$ can be expanded into a power series:

$$H(x, z) = \sum_{|\beta| = 1}^{\infty} H^{(\beta)}(x) \frac{z^\beta}{|\beta|!}, \quad (6.2)$$

where $H^{(\beta)}(x) \in C^{2+\alpha}(\mathbb{T}^n)$ and $\beta$ is a muti-index.

Similar to our discussion in remark 2.1, we always assume that the coefficient functions $H^{(\beta)}$ in (6.2) are real-valued. We first state the main theorems of the results for the inverse problems associated with (6.1). The corresponding proofs are given in section 6.2.

**Theorem 6.1.** Assume $F_j \in \mathcal{B}$ $(j = 1, 2)$, $G \in \mathcal{B}$ and $H \in \mathcal{I}$. Let $M_{F_j}$ be the measurement map associated to the following system $(j = 1, 2)$:

$$\begin{align*}
-\partial_t u(x, t) - \Delta u(x, t) + H(x, \nabla u) &= F_j(x, m(x, t)), & \text{in } \mathbb{T}^n \times (0, T), \\
\partial_t m(x, t) - \Delta m(x, t) - \text{div}(m(x, t)H_p(x, \nabla u)) &= 0, & \text{in } \mathbb{T}^n \times (0, T), \\
u(x, T) &= G_j(x, m_T), & \text{in } \mathbb{T}^n, \\
m(x, 0) &= m_0(x), & \text{in } \mathbb{T}^n.
\end{align*} \quad (6.3)$$

If for any $m_0 \in C^{2+\alpha}(\mathbb{T}^n) \cap \mathcal{O}$, one has

$$M_{F_1}(m_0) = M_{F_2}(m_0),$$

then it holds that

$$F_1(x, z) = F_2(x, z) \quad \text{in } \mathbb{T}^n \times \mathbb{R}.$$ 

**Theorem 6.2.** Assume $F \in \mathcal{B}$, $G_j \in \mathcal{B}$ $(j = 1, 2)$ and $H \in \mathcal{I}$. Let $M_{G_1}$ be the measurement map associated to the following system $(j = 1, 2)$:

$$\begin{align*}
-\partial_t u(x, t) - \Delta u(x, t) + H(x, \nabla u) &= F(x, t, m(x, t)), & \text{in } \mathbb{T}^n \times (0, T), \\
\partial_t m(x, t) - \Delta m(x, t) - \text{div}(m(x, t)H_p(x, \nabla u)) &= 0, & \text{in } \mathbb{T}^n \times (0, T), \\
u(x, T) &= G_j(x, m_T), & \text{in } \mathbb{T}^n, \\
m(x, 0) &= m_0(x), & \text{in } \mathbb{T}^n.
\end{align*} \quad (6.4)$$

If for any $m_0 \in C^{2+\alpha}(\mathbb{T}^n) \cap \mathcal{O}$, one has

$$M_{G_1}(m_0) = M_{G_2}(m_0),$$

then it holds that

$$G_1(x, z) = G_2(x, z) \quad \text{in } \mathbb{T}^n \times \mathbb{R}.$$
6.1. Well-posedness of the general system

Lemma 6.1. Suppose \( F, G \in \mathcal{B}, H \in \mathcal{I} \). Then there exist \( \delta > 0, C > 0 \) such that for any \( m_0 \in B_2(\mathbb{T}^n) := \{ m_0 \in C^2(\mathbb{T}^n) : ||m_0||_{C^{1+\alpha}(\mathbb{T}^n)} \leq \delta \} \), the MFG system (6.1) has a solution \( u = u_{m_0} \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q) \) which satisfies

\[
||u||_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)} + ||m||_{C^{1+\alpha}(\mathbb{T}^n)} \leq C ||m_0||_{C^{1+\alpha}(\mathbb{T}^n)}. \tag{6.5}
\]

Furthermore, the solution \((u, m)\) is unique within the class

\[
\left\{ (u, m) \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q)^2 : ||(u, m)||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\mathbb{T}^n)^2} \leq C \delta \right\}, \tag{6.6}
\]

where

\[
||(u, m)||_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)^2} := ||u||_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)} + ||m||_{C^{2+\alpha,1+\frac{\alpha}{2}}(Q)}, \tag{6.7}
\]

and it depends holomorphically on \( m_0 \in C^{2+\alpha}(\mathbb{T}^n) \).

The proof of lemma 6.1 follows from a similar argument to that of lemma 3.1. We choose to skip it.

6.2. Proofs of theorems 6.1 and 6.2

We first introduce the general heat kernel to recover the unknown functions in a parabolic system. The construction and basic properties of the general heat kernel can be found in [29].

Lemma 6.2. Let \( F_1, F_2, f, g \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q), \quad A(x) \in C^{2+\alpha,1+\frac{\alpha}{2}}(\mathbb{T}^n)^n \).

Consider the following system

\[
\begin{aligned}
\partial_t u_i(x, t) - \Delta u_i(x, t) + A(x) \cdot \nabla u_i &= F_i(x)v(x, t) + f(x, t), & \text{in } \mathbb{T}^n \times (0, T), \\
u_i(x, 0) &= g(x), & \text{in } \mathbb{T}^n.
\end{aligned} \tag{6.8}
\]

Suppose for any \( v(x, t) \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q) \), we have \( u_1(x, T; v) = u_2(x, T; v) \). Then it holds that \( F_1 = F_2 \).

Proof. Let \( L = \partial_t - \Delta + A \cdot \nabla (\cdot) \) and \( K(x, y, t) \) be the solution of the following Cauchy problem

\[
\begin{aligned}
L(K(x, t)) &= 0, \quad t > 0, \quad x \in \mathbb{R}^n, \\
K(x, 0) &= \delta(x).
\end{aligned}
\]

Then one has that

\[
u_i(x, t) = \int_{\mathbb{T}^n} K(x - y, t)g(y)dy + \int_0^t \int_{\mathbb{T}^n} K(x - y, t - s)(F_i(y)v(y, s) + f(y, s))dyds.
\]

Since we have \( u_1(x, T; v) = u_2(x, T; v) \), it follows that

\[
\int_0^T \int_{\mathbb{T}^n} K(x - y, T - s)(F_1(y) - F_2(y))v(y, s)dyds = 0. \tag{6.9}
\]

By absurdity, we assume that there is \( y_0 \in \mathbb{T}^n \) such that \( F_1(y_0) \neq F_2(y_0) \). Then there is a neighborhood \( U \) of \( y_0 \) such that \( F_1 - F_2 > 0 \) or \( F_1 - F_2 < 0 \) in \( U \). Since \( K(x - y, T - s) > 0 \) and (6.9) holds for all \( v \in C^{2+\alpha,1+\frac{\alpha}{2}}(Q) \). We may choose \( v \) such that \( K(x - y, T - s)(F_1(y) - F_2(y))v(y, s) \) is negative (respectively, positive) in \( U \). Then

\[
\int_0^T \int_{U} K(x - y, T - s)(F_1(y) - F_2(y))v(y, s)dyds < 0
\]

(this is a contradiction).
\( F_2(y)v(y,s) > 0 \) in \( U \) and \( K(x-y,T-s)(F_1(y) - F_2(y))v(y,s) = 0 \) in \( T^n \setminus U \). It is a contradiction. Therefore, we have \( F_1 = F_2 \).

The proof is complete.

Before we present the proofs for theorems 6.1 and 6.2, we first perform the higher order linearization for the MFG system (6.1), which follows a similar strategy to that developed in section 5.1. Let

\[
 m_0(x;\varepsilon) = \sum_{i=1}^{N} \epsilon_i f_i,
\]

where \( f_i \in C^{2+\alpha}(T^n) \) and \( \varepsilon = (\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_N) \in \mathbb{R}_+^N \) with \( |\varepsilon| = \sum_{i=1}^{N} |\varepsilon_i| \) small enough.

Then by lemma 6.1, there exists a unique solution \((u(x,t;\varepsilon), m(x,t;\varepsilon))\) of (6.1). Let \((u(x,t;0), m(x,t;0))\) be the solution of (6.1) when \( \varepsilon = 0 \). Notice that if \( H \in \mathcal{I} \), then \((u(x,t;0), m(x,t;0)) = (0,0)\).

Let

\[
 u^{(1)} := \partial_x u|_{\varepsilon = 0},
 m^{(1)} := \partial_x m|_{\varepsilon = 0}.
\]

Suppose \( H \in \mathcal{I} \), \( F \in \mathcal{A} \) and \( G \in \mathcal{B} \), we have

\[
 \partial_t m^{(1)}(x,t) - \Delta m^{(1)}(x,t)
 = \lim_{\varepsilon \to 0} \frac{1}{\varepsilon} \left[ -H(x, \nabla u(x,t;\varepsilon)) + H(x,u(x,t;0)) + F(x,u(x,t;\varepsilon)) - F(x,u(x,t;0)) \right]
 = \lim_{\varepsilon \to 0} \frac{1}{\varepsilon} \left[ \sum_{|\beta| = 1}^\infty H^{(\beta)}(x) \frac{\varepsilon^\beta}{\beta!} + F^{(1)}(x) m^{(1)}(x,t) \right]
 = -A^{(1)}(x) \cdot \nabla u + F^{(1)}(x)m^{(1)}(x,t),
\]

where \( A^{(1)}(x) = (H^{(1,0,0,\ldots,0)}(x), H^{(0,1,0,\ldots,0)}(x), \ldots, H^{(0,0,\ldots,1)}(x)). \)

Moreover, we have

\[
 \partial_x \text{div}(m(x,t)H_\rho(x,\nabla u))|_{\varepsilon = 0}
 = \partial_x \text{div}(m(x,t)A^{(1)}(x)) + \partial_x \text{div}(m(x,t)B^{(1)}(x) \cdot \nabla u)|_{\varepsilon = 0}
 = \partial_x \text{div}(m(x,t)A^{(1)}(x))
\]

where

\[
 B^{(1)}(x) = \left( \sum_{|\beta| = 1} H^{(1,\beta)}(x), \sum_{|\alpha| + |\beta| = 1, \alpha \in \mathbb{R}} H^{(\alpha,1,\beta)}(x), \ldots, \sum_{|\alpha| = 1, \alpha \in \mathbb{R}^{r-1}} H^{(\alpha,\ldots,1)}(x) \right).
\]

Hence, we can see that \((u^{(1)}, m^{(1)})\) satisfies the following system:

\[
 \begin{align*}
 -\partial_t u^{(1)}(x,t) - \Delta u^{(1)}(x,t) + A^{(1)}(x) \cdot \nabla u &= F^{(1)}(x)m^{(1)}(x,t), & \text{in } T^n \times (0,T), \\
 \partial_t m^{(1)}(x,t) - \Delta m^{(1)}(x,t) - \text{div}(m^{(1)}(x,t)A^{(1)}(x)) &= 0, & \text{in } T^n \times (0,T), \\
 u^{(1)}(x,T) &= G^{(1)}(x)m^{(1)}(x,T), & \text{in } T^n, \\
 m^{(1)}(x,0) &= f_1(x), & \text{in } T^n,
\end{align*}
\]

(6.12)
Here, we make a key observation that the non-linear terms and source terms in higher-order linearization system only depend on the solutions of the lower-order linearization system. Hence, as an illustrative case for our argument, we only compute the second order linearization system. Let

\[ u^{(1,2)} := \partial_1 \partial_2 u |_{\varepsilon=0}, m^{(1,2)} := \partial_1 \partial_2 m |_{\varepsilon=0}, \]

and

\[ u^{(2)} := \partial_2 u |_{\varepsilon=0}, m^{(2)} := \partial_2 m |_{\varepsilon=0}. \]

Recall the derivation of the system (5.5) in section 5.1. By direct calculations, we have

\[ -\partial_t u^{(1,2)} - \Delta u^{(1,2)} = -\partial_1 \partial_2 H(x, \nabla u)|_{\varepsilon=0} + F^{(1)}(x)m^{(1,2)} + F^{(2)}(x)m^{(1)}m^{(2)} \]

\[ = -\partial_1 \partial_2 \left( \sum_{|\beta|=1} \partial_t H^{(\beta)}(x) \frac{\varepsilon^{|\beta|}}{K^{|\beta|}} \right) |_{\varepsilon=0} + F^{(1)}(x)m^{(1,2)} + F^{(2)}(x)m^{(1)}m^{(2)} \]

\[ = -A^{(1)} \cdot \nabla u^{(1,2)} - \sum_{|\beta|=2} \partial_t H^{(\beta)}(x)m^{(1)}u^{(2)} + F^{(1)}(x)m^{(1,2)} + F^{(2)}(x)m^{(1)}m^{(2)}. \]

Now, with the discussion above at hand and lemma 6.2, we are now in a position to present the proofs of theorems 6.1 and 6.2.

**Proof of theorem 6.1.** Consider the following MFG systems for \( j = 1, 2 \):

\[
\begin{align*}
-\partial_t u_j(x,t) - \Delta u_j(x,t) + H(x, \nabla u_j) &= F_j(x,m(x,t)), \quad \text{in } \mathbb{T}^n \times (0,T), \\
\partial_t m_j(x,t) - \Delta m_j(x,t) - \text{div}(m_j(x,t)H_p(x, \nabla u_j)) &= 0, \quad \text{in } \mathbb{T}^n \times (0,T), \\
u_j(x,T) &= G(x, m_T), \quad \text{in } \mathbb{T}^n, \\
m_j(x,0) &= m_0(x), \quad \text{in } \mathbb{T}^n.
\end{align*}
\]

(6.14)

Recall the higher order linearization method in section 5.1. Let

\[ u_j^{(1)} := \partial_1 u_j |_{\varepsilon=0}, \]

\[ m_j^{(1)} := \partial_1 m_j |_{\varepsilon=0}. \]

By combining (6.10)–(6.12), we can deduce that

\[
\begin{align*}
-\partial_t u_j^{(1)}(x,t) - \Delta u_j^{(1)}(x,t) + A^{(1)}(x) \cdot \nabla u_j &= F_j^{(1)}(x) m_j^{(1)}(x,t), \quad \text{in } \mathbb{T}^n \times (0,T), \\
\partial_t m_j^{(1)}(x,t) - \Delta m_j^{(1)}(x,t) - \text{div}(m_j^{(1)}(x,t)A^{(1)}(x)) &= 0, \quad \text{in } \mathbb{T}^n \times (0,T), \\
u_j^{(1)}(x,T) &= G^{(1)}(x)m_j^{(1)}(x,T), \quad \text{in } \mathbb{T}^n, \\
m_j^{(1)}(x,0) &= f_1(x), \quad \text{in } \mathbb{T}^n,
\end{align*}
\]

(6.15)

where

\[ A^{(1)}(x) = (H^{(1,0,0,\ldots,0)}(x), H^{(0,1,0,\ldots,0)}(x), \ldots, H^{(0,0,\ldots,1)}(x)). \]

We extend \( f_1 \) from \( \mathbb{T}^n \) to \( \mathbb{R}^n \) periodically, and still denote it by \( f_1 \). By lemma 3.1, \( m_j^{(1)} \) is unique determined by \( f_1(x) \). We use change of variables as well as a similar strategy in the proof of lemma 6.2.

24
Suppose \( F_1^{(1)}(x) \neq F_2^{(1)}(x) \), then there is an open subset \( U \subset \mathbb{T}^n \) such that \( F_1^{(1)}(x) \neq F_2^{(1)}(x) \) in \( U \). Given \( \varepsilon > 0 \), there exists \( f \in C^{1+\eta}_{\text{loc}}(\mathbb{T}^n) \) such that \( ||f - \chi_U||_{L^2(\mathbb{T}^n)} \leq \varepsilon \), where \( \chi_U \) is the characteristic function of \( U \). Then the classical prior estimate implies that
\[
||m_1^{(1)}(x,t) - \chi_{U \times (0,T)}||_{L^2(Q)} \leq C\varepsilon,
\]
for some constant \( C > 0 \).

This implies that
\[
\int_0^T \int_{\mathbb{T}^n} K(x - y, T - s)(F_1^{(1)}(y) - F_2^{(1)}(y))\chi_U(y,s) \, dy \, ds = 0. \tag{6.16}
\]

Since \( K > 0 \) in \( Q \), it is a contradiction. Hence, \( F_1^{(1)}(x) = F_2^{(1)}(x) \).

Next, we can consider the case \( N = 2 \). Let
\[
u_j^{(1,2)} := \partial_{x_1}\partial_{x_2}u_j|_{\varepsilon=0}, \quad m_j^{(1,2)} := \partial_{x_1}\partial_{x_2}m_j|_{\varepsilon=0},
\]
and
\[
u_j^{(2)} := \partial_{x_1}m_j|_{\varepsilon=0}, \quad m_j^{(2)} := \partial_{x_1}m_j|_{\varepsilon=0}.
\]

We can conduct the second-order linearization. Following a similar process as that in (6.13), we can deduce that
\[
\begin{aligned}
-\partial_t u_j^{(1,2)} - \Delta u_j^{(1,2)} + A^{(1)} \cdot \nabla u_j^{(1,2)} + R_1(x,t) \\
= F_1^{(1)}(x)m_j^{(1,2)} + F_2^{(2)}(x)m_j^{(2)}, \\
\partial_t m_j^{(1,2)}(x,t) - \Delta m_j^{(1,2)}(x,t) - \text{div}(m_j^{(1)}(x,t)A^{(1)}(x)) \\
= R_2(x,t), \\
u_j^{(1,2)}(x,t) = G^{(2)}(x)m_j^{(1,2)}(x,t), \\
m_j^{(1,2)}(x,0) = 0,
\end{aligned}
\tag{6.17}
\]
where
\[
R_1(x,t) = \sum_{|\beta|=2} H^{(3)}(x)u_j^{(1)}u_j^{(2)},
\]
and
\[
R_2(x,t) = \text{div}(m_j^{(1)}U^{(2)}) + \text{div}(m_j^{(2)}U^{(1)}).
\]

Here, the \( f \)th component of \( U^{(1)} \) is
\[
U_j^{(1)} = \sum_{i=1}^n \frac{\partial^2 H}{\partial z_i \partial z_i}(x,0) \frac{\partial \nu_j^{(2)}}{\partial x_i},
\]
and the \( f \)th component of \( U^{(2)} \) is
\[
U_j^{(2)} = \sum_{i=1}^n \frac{\partial^2 H}{\partial z_i \partial z_i}(x,0) \frac{\partial \nu_j^{(1)}}{\partial x_i}.
\]

Following a similar argument to the case \( N = 1 \) (considering \( m_0 = \varepsilon_0 \phi_2 \)), we have
\[
u_1^{(1)}(x,t) = \nu_2^{(1)}(x,t), \quad u_1^{(2)}(x,t) = u_2^{(2)}(x,t),
\]
and
and
\[ m_1^{(1)}(x, t) = m_2^{(1)}(x, t), \quad m_1^{(2)}(x, t) = m_2^{(2)}(x, t). \]

By lemma 3.1, \( m_j^{(1,2)} \) is unique determined by \( f_1(x), f_2(x) \) and \( G^{(1)}(x) \). By a similar argument, we readily have \( F_1^{(2)}(x) = F_2^{(2)}(x) \).

Finally, by a mathematical induction, we can show the same result holds for \( N \geq 3 \). That is, for any \( k \in \mathbb{N} \), we have \( F_1^{(k)}(x) = F_2^{(k)}(x) \). Therefore, we have \( F_1(x, z) = F_2(x, z) \).

The proof is complete.

We proceed with the proof of theorem 6.2. To that end, we first state an auxiliary lemma, which is an analogue to lemma 6.2, and omit its proof.

**Lemma 6.3.** Let \( g_1, g_2 \in C^{2+\alpha}(T^n) \) and \( A(x) \in C^{2+\alpha}(T^n) \). Consider the following systems with \( f \in C^{2+\alpha, 1+\frac{\alpha}{2}}(Q) \) and \( j = 1, 2 \):
\[
\begin{align*}
\frac{\partial u_j(x, t)}{\partial x} - \Delta u_j(x, t) &+ A(x) \cdot \nabla u_j = f_j(x, t), \quad \text{in} \quad T^n \times (0, T), \\
u_j(x, 0) &= g_j(x), \quad \text{in} \quad T^n, \\
m_j(x, 0) &= m_0(x), \quad \text{in} \quad T^n.
\end{align*}
\] (6.18)

Suppose for any \( v \in C^{2+\alpha, 1+\frac{\alpha}{2}}(Q) \), we have \( u_1(x, T; v) = u_2(x, T; v) \). Then it holds that \( g_1(x) = g_2(x) \).

Next, we give the proof of theorem 6.2.

**Proof of theorem 6.2.** We shall follow a similar strategy that was developed for the proof of theorem 6.1. Consider the following systems for \( j = 1, 2 \):
\[
\begin{align*}
-\frac{\partial m_j(x, t)}{\partial x} - \Delta m_j(x, t) + H(x, \nabla u_j) &= F_j(x, m(x, t)), \quad \text{in} \quad T^n \times (0, T), \\
\frac{\partial m_j(x, t)}{\partial x} - \Delta m_j(x, t) - \text{div}(m_j(x, t)H_j(x, \nabla u_j)) &= 0, \quad \text{in} \quad T^n \times (0, T), \\
u_j(x, T) &= G_j(x, m_T), \quad \text{in} \quad T^n, \\
m_j(x, 0) &= m_0(x), \quad \text{in} \quad T^n.
\end{align*}
\] (6.19)

We next perform the successive linearization process. Consider the case \( N = 1 \). Let
\[
\begin{align*}
u_j^{(1)}(x, t) &= \frac{\partial u_j}{\partial x}|_{x=0}, \\
m_j^{(1)}(x, t) &= \frac{\partial m_j}{\partial x}|_{x=0}.
\end{align*}
\]

By direct computations, one can show that \((u_j^{(1)}, v_j^{(1)})\) satisfies the following system:
\[
\begin{align*}
-\frac{\partial u_j^{(1)}(x, t)}{\partial x} - \Delta u_j^{(1)}(x, t) + A^{(1)}(x) \cdot \nabla u_j &= \overline{F_j^{(1)}}(x)m_j^{(1)}(x, t), \quad \text{in} \quad T^n \times (0, T), \\
\frac{\partial m_j^{(1)}(x, t)}{\partial x} - \Delta m_j^{(1)}(x, t) - \text{div}(m_j^{(1)}(x, t)A^{(1)}(x)) &= 0, \quad \text{in} \quad T^n \times (0, T), \\
u_j^{(1)}(x, T) &= G^{(1)}(x)m_j^{(1)}(x, T), \quad \text{in} \quad T^n, \\
m_j^{(1)}(x, 0) &= f_j(x), \quad \text{in} \quad T^n.
\end{align*}
\] (6.20)

We can solve this system by first deriving \( m_j^{(1)} \) and then obtaining \( u_j^{(1)} \). Since \( \mathcal{M}_{G_1} = \mathcal{M}_{G_2} \), we have
\[
\begin{align*}
u_1^{(1)}(x, 0) &= \nu_2^{(1)}(x, 0), \\
u_1^{(1)}(x, 0) &= \nu_2^{(1)}(x, 0), \quad \text{for all} \quad f_j \in C^{2+\alpha}(T^n). \quad \text{By lemma 6.3, we readily see that} \quad G_1^{(1)}(x) = G_2^{(2)}(x).
\end{align*}
\]
Finally, by following a similar argument in the proof of theorem 6.1, we can conduct the higher-order linearization process to show that \( G^{(k)}_1(x) = G^{(k)}_2(x) \) for all \( k \in \mathbb{N} \). Hence, \( G_1(x,z) = G_2(x,z) \).

The proof is complete.

Data availability statement

No new data were created or analysed in this study.

Acknowledgments

Authors’ Note

The current article is the first theoretical work on inverse problems for mean field games. Its preprint version was posted in arXiv in May 2022 [40]. More recently, there are a few new theoretical developments on the MFG theory from the perspective of inverse problems; see [41, 42] for related works associated with infinitely many measurements; and [43–48] for related works associated with a single-event measurement.
