A POINT OF VIEW ON GOWERS UNIFORMITY NORMS

BERNARD HOST AND BRYNA KRA

Abstract. Gowers norms have been studied extensively both in the direct sense, starting with a function and understanding the associated norm, and in the inverse sense, starting with the norm and deducing properties of the function. Instead of focusing on the norms themselves, we study associated dual norms and dual functions. Combining this study with a variant of the Szemerédi Regularity Lemma, we give a decomposition theorem for dual functions, linking the dual norms to classical norms and indicating that the dual norm is easier to understand than the norm itself. Using the dual functions, we introduce higher order algebras that are analogs of the classical Fourier algebra, which in turn can be used to further characterize the dual functions.

1. Introduction

In his seminal work on Szemerédi’s Theorem, Gowers [1] introduced uniformity norms $U(d)$ for each integer $d \geq 1$, now referred to as Gowers norms or Gowers uniformity norms, that have played an important role in the developments in additive combinatorics over the past ten years. In particular, Green and Tao [3] used Gowers norms as a tool in their proof that the primes contain arbitrarily long arithmetic progressions in the primes; shortly thereafter, they made a conjecture [5], the Inverse Conjecture for the Gowers norms, on the algebraic structures underlying these norms. Related seminorms were introduced by the authors [8] in the setting of ergodic theory, and the ergodic structure theorem provided a source of motivation in the formulation of the Inverse Conjecture. For each integer $d \geq 1$ and $\delta > 0$, Green and Tao introduce a class $\mathcal{F}(d, \delta)$ of “$(d - 1)$-step nilsequences of bounded complexity,” which we do not define here, and the proof of the Inverse Conjecture was given:

Inverse Theorem for Gowers Norms (Green, Tao, and Ziegler [7]). For each integer $d \geq 1$ and $\delta > 0$, there exists a constant $C = C(d, \delta) > 0$. The first author was partially supported by the Institut Universitaire de France and the second author by NSF grant 0900873.
0 such that for every function $f$ on $\mathbb{Z}/N\mathbb{Z}$ with $|f| \leq 1$ and $\|f\|_{U(d)} \geq \delta$, there exists $g \in \mathcal{F}(d, \delta)$ with $\langle g; f \rangle \geq C$.

See also Szegedy’s approach to the Inverse Conjecture, outlined in the announcement [12] for the article [11].

We are motivated by the work of Gowers in [2]. Several ideas come out of this work, in particular the motivation that algebra norms are easier to study. The Gowers norms $U(d)$ are classically defined in $\mathbb{Z}/N\mathbb{Z}$, but we choose to work in a general compact abelian group. For most of the results presented here, we take care to distinguish between the group $\mathbb{Z}/N\mathbb{Z}$ and the interval $[1, \ldots, N]$, of the natural numbers $\mathbb{N}$, whereas for applications in additive combinatorics, the results may be more directly proved without this separation. This is a conscious choice that allows us to separate what about Gowers norms is particular to the combinatorics of $\mathbb{Z}/N\mathbb{Z}$ and what is more general. Our point of view is that of harmonic analysis, rather than combinatorial.

More generally, the Gowers norms can be defined on a nilmanifold. This is particularly important in the ergodic setting where analogous seminorms were defined by the authors in [8] in an arbitrary measure space; these seminorms are exactly norms when the space is a nilmanifold. While we restrict ourselves to abelian groups in this article, most of the results can be carried out in the more general setting of a nilmanifold without significant changes.

Instead of focusing on the Gowers norms themselves, we study the associated dual norms that fit within this framework and the associated dual functions. Moreover, in the statement of the inverse theorem, and more generally in uses of the Gowers norms, one typically assumes that the functions are bounded by 1. From the duality point of view, instead we study functions in the dual space itself, we can consider functions that are within a small $L^1$ error from functions in this space. This allows us to restrict ourselves to dual functions of functions in a certain $L^p$ class (Theorem 3.8). Moreover, we rephrase the Inverse Theorem in terms of dual functions (see Section 2.2 for precise meanings of the term) in certain $L^p$ classes, and in this form the Gowers norms do not appear explicitly (Section 3.3). This reformulates the Inverse Theorem more in a classical analysis context.

The dual functions allow us to introduce algebras of functions on the compact abelian group $\mathbb{Z}$. For $d = 2$, this corresponds to the classical Fourier algebra. Finding an interpretation for the higher order uniformity norms is hard and no analogs of Fourier analysis and simple formulas, such as Parseval, exist. For $d > 2$, the higher order Fourier algebra are analogs of the classical case of the Fourier algebra. These
algebras allow us to further describe the dual functions. Starting with a dual function of level $d$, we find that it lies in the Fourier algebra of order $d$, giving us information on its dual norm $U(d)^*$, and by an approximation result, we understand further the original function.

We obtain a result on compactness (Theorem 5.2) of dual functions, by applying a variation of the classical Szemerédi Regularity Lemma.

2. Gowers norms: definition and elementary bounds

2.1. Notation. Throughout, we assume that $Z$ is a compact abelian group and let $\mu$ denote Haar measure on $Z$. If $Z$ is finite, then $\mu$ is the uniform measure; the classical case to keep in mind is when $Z = \mathbb{Z}_N = \mathbb{Z}/N\mathbb{Z}$ and the measure of each element is $1/N$.

All functions are implicitly assumed to be real valued. When $Z$ is infinite, we also implicitly assume that all functions and sets are measurable. For $1 \leq p \leq \infty$, $\|\cdot\|_p$ denotes the $L^p(\mu)$ norm; if there is a need to specify the measure, write $\|\cdot\|_p(\mu)$ or $\|\cdot\|_p(Z)$ when we wish to emphasize the space.

We fix an integer $d \geq 1$ throughout and the dependence on $d$ is implicit in all statements.

We have various spaces of various dimensions: $1$, $d$, $2^d$. Ordinary letters $t$ are reserved for spaces of one dimension, vector notation $\vec{t}$ for dimension $d$, and bold face characters $\mathbf{t}$ for dimension $2^d$.

If $f$ is a function on $Z$ and $t \in Z$, we write $f_t$ for the function on $Z$ defined by

$$f_t(x) = f(x + t),$$

where $x \in Z$. If $f$ is a $\mu$-integrable function on $Z$, we write

$$\mathbb{E}_{x \in Z} f(x) = \int f(x) \, d\mu(x).$$

We use similar notation for multiple integrals. If $f$ and $g$ are functions on $Z$, we write

$$\langle f; g \rangle = \mathbb{E}_{x \in Z} f(x) g(x),$$

assuming that the integral on the right hand side is defined.

If $d$ is a positive integer, we set

$$V_d = \{0, 1\}^d.$$ Elements of $V_d$ are written as $\vec{\epsilon} = \epsilon_1 \epsilon_2 \cdots \epsilon_d$, without commas or parentheses. Writing $\vec{0} = 00 \cdots 0 \in V_d$, we set

$$\tilde{V}_d = V_d \setminus \{\vec{0}\}.$$ For $x \in \mathbb{Z}^{2^d}$, we write $x = (x_{\vec{\epsilon}}; \vec{\epsilon} \in V_d)$. 

For $\vec{e} \in V_d$ and $\vec{t} = (t_1, t_2, \ldots, t_d) \in Z^d$ we write
\[
\vec{e} \cdot \vec{t} = \epsilon_1 t_1 + \epsilon_2 t_2 + \cdots + \epsilon_d t_d.
\]

2.2. The uniformity norms and the dual functions: definitions.
The uniformity norms, or Gowers norms, $\|f\|_{U(d)}$, $d \geq 2$, of a function $f \in L^\infty(\mu)$ are defined inductively by
\[
\|f\|_{U(1)} = |E_x f(x)|
\]
and for $d \geq 2$,
\[
\|f\|_{U(d)} = \left( \mathbb{E}_t \|f \cdot f_t\|_{U(d-1)}^{2d-1} \right)^{1/2d}.
\]
Note that $\|\cdot\|_{U(1)}$ is not actually a norm. (See [1] for more on these norms and [8] for a related seminorm in ergodic theory.) If there is ambiguity as to the underlying group $Z$, we write $\|\cdot\|_{U(Z,d)}$.

These norms can also be defined by closed formulas:
\[
\|f\|_{U(1)}^{2d} = \mathbb{E}_{x, \vec{t} \in Z \times Z^d} \prod_{\vec{e} \in V_d} f(x + \vec{e} \cdot \vec{t}).
\]
We can rewrite this formula. Let $Z_d$ be the subset of $Z^{2d}$ defined by
\[
Z_d = \{ (x + \vec{e} \cdot \vec{t} : \vec{e} \in V_d) : x \in Z, \vec{t} \in Z^d \}.
\]
This set can be viewed as the “set of cubes of dimension $d$” (see, for example, [1] or [8]). It is easy to check that $Z_d$ is a closed subgroup of $Z^{2d}$. Let $\mu_d$ denote its Haar measure. Then $Z_d$ is the image of $Z^{d+1} = Z \times Z^d$ under the map $(x, \vec{t}) \mapsto (x + \vec{e} \cdot \vec{t} : \vec{e} \in V_d)$. Furthermore, $\mu_d$ is the image of $\mu \times \mu \times \cdots \times \mu$ (taken $d + 1$ times) under the same map. If $f_{\vec{e}}, \vec{e} \in V_d$, are functions in $L^\infty(\mu)$, then
\[
\mathbb{E}_{x, \vec{t} \in Z \times Z^d} \prod_{\vec{e} \in V_d} f_{\vec{e}}(x + \vec{e} \cdot \vec{t}) = \int_{Z_d} \prod_{\vec{e} \in V_d} f_{\vec{e}}(x) \, d\mu_d(x).
\]
In particular, for $f \in L^\infty(\mu)$,
\[
\|f\|_{U(d)}^{2d} = \int_{Z_d} \prod_{\vec{e} \in V_d} f(x) \, d\mu_d(x).
\]
Associating the coordinates of the set $V_d$ with the coordinates of the Euclidean cube, we have that the measure $\mu_d$ is invariant under permutations that are associated to the isometries of the Euclidean cube. These permutations act transitively on $V_d$.

For $d = 2$, by Parseval’s identity we have that
\[
\|f\|_{U(2)} = \|\hat{f}\|_{\ell^4(\mathbb{Z})},
\]
where \( \hat{Z} \) is the dual group of \( Z \) and \( \hat{f} \) is the Fourier transform of \( f \). For \( d \geq 3 \), no analogous simple formula is known and the interpretation of the Gowers uniformity norms is more difficult. A deeper understanding of the higher order norms is, in part, motivation for the current work.

We make use of the “Cauchy-Schwarz-Gowers Inequality” (CSG) used in the proof of the subadditivity of Gowers norms:

**Cauchy-Schwarz-Gowers Inequality.** Let \( f_\vec{\epsilon}, \vec{\epsilon} \in V_d \), be \( 2^d \) functions belonging to \( L^\infty(\mu) \). Then

\[
\left| \mathbb{E}_{x \in Z, \vec{\epsilon} \in Z^d} f_\vec{\epsilon}(x + \vec{\epsilon} \cdot \vec{t}) \right| = \left| \int_{Z^d} \prod_{\vec{\epsilon} \in \tilde{V}_d} f_\vec{\epsilon}(x) \, d\mu_d(x) \right| \leq \prod_{\vec{\epsilon} \in \{0,1\}^d} \| f_\vec{\epsilon} \|_{U(d)}.
\]

Applying the Cauchy-Schwarz-Gowers Inequality with half of the functions equal to \( f \) and the other half equal to the constant 1, we deduce that

\[
\| f \|_{U(d+1)} \geq \| f \|_{U(d)}
\]

for every \( f \in L^\infty(Z) \).

**Definition 2.1.** For \( f \in L^\infty(\mu) \), define the dual function \( \mathcal{D}_d f \) on \( Z \) by

\[
(5) \quad \mathcal{D}_d f(x) = \mathbb{E}_{\vec{\epsilon} \in Z^d} \prod_{\vec{\epsilon} \in \tilde{V}_d} f(x + \vec{\epsilon} \cdot \vec{t}).
\]

It follows from the definition that

\[
(6) \quad \| f \|_{U(d)}^{2d} = \langle \mathcal{D}_d f; f \rangle.
\]

More generally, we define:

**Definition 2.2.** If \( f_\vec{\epsilon} \in L^\infty \) for \( \vec{\epsilon} \in \tilde{V}_d \), we denote

\[
(7) \quad \mathcal{D}_d(f_\vec{\epsilon}; \vec{\epsilon} \in \tilde{V}_d)(x) = \mathbb{E}_{\vec{\epsilon} \in Z^d} \prod_{\vec{\epsilon} \in \tilde{V}_d} f_\vec{\epsilon}(x + \vec{\epsilon} \cdot \vec{t}).
\]

We call such a function the cubic convolution product of the functions \( f_\vec{\epsilon} \).

There is a formal similarity between the cubic convolution product and the classic convolution product; for example,

\[
\mathcal{D}_2(f_{01}, f_{10}, f_{11})(x) = \mathbb{E}_{t_1, t_2 \in Z} f_{01}(x + t_1) f_{10}(x + t_2) f_{11}(x + t_1 + t_2).
\]
2.3. Elementary bounds. For \( \bar{e} \in V_d \) and \( \alpha \in \{0, 1\} \), we write \( \bar{e} \alpha = \epsilon_1 \ldots \epsilon_d \alpha \in V_{d+1} \), maintaining the convention that such elements are written without commas or parentheses. Thus

\[
V_{d+1} = \{\epsilon 0 : \bar{e} \in V_d\} \cup \{\epsilon 1 : \bar{e} \in V_d\}.
\]

The image of \( Z_{d+1} \) under each of the two natural projections on \( Z^2 \) is \( Z_d \), and the image of the measure \( \mu_{d+1} \) under these projections is \( \mu_d \).

Lemma 2.3. Let \( f_{\bar{e}}, \bar{e} \in \tilde{V}_d \), be \( 2^d - 1 \) functions in \( L^\infty(\mu) \). Then for all \( x \in Z \),

\[
|D_d(f_{\bar{e}} : \bar{e} \in \tilde{V}_d)(x)| \leq \prod_{\bar{e} \in \tilde{V}_d} \|f_\bar{e}\|_{2^d-1}.
\]

In particular, for every \( f \in L^\infty(\mu) \),

\[
\|D_d f\|_\infty \leq \|f\|_{2^d-1}^{2^d-1}.
\]

Proof. Without loss, we can assume that all functions are nonnegative. We proceed by induction on \( d \geq 2 \).

For nonnegative \( f_{01}, f_{10} \) and \( f_{11} \in L^\infty(\mu) \),

\[
D_2(f_{01}, f_{10}, f_{11})(x) = \mathbb{E}_{t_1 \in Z} f_{01}(x + t_1) \mathbb{E}_{t_2 \in Z} f_{10}(x + t_2) f_{11}(x + t_1 + t_2) \\
\leq \mathbb{E}_{t_1 \in Z} f_{01}(x + t_1) \|f_{10}\|_{L^2(\mu)} \|f_{11}\|_{L^2(\mu)} \\
\leq \|f_{01}\|_{L^2(\mu)} \|f_{10}\|_{L^2(\mu)} \|f_{11}\|_{L^2(\mu)}.
\]

This proves the case \( d = 2 \). Assume that the result holds for some \( d \geq 2 \). Let \( f_{\bar{e}}, \bar{e} \in \tilde{V}_{d+1} \), be nonnegative and belong to \( L^{2^d}(\mu) \). Then

\[
D_{d+1}(f_{\bar{e}} : \bar{e} \in \tilde{V}_{d+1})(x) = \mathbb{E}_{\bar{s} \in \tilde{Z}_d} \left( \prod_{\bar{\eta} \in \tilde{V}_d} f_{\bar{\eta}0}(x + \bar{\eta} \cdot \bar{s}) \mathbb{E}_{\alpha \in \tilde{Z}_d} \prod_{\bar{\theta} \in \tilde{V}_d} f_{\bar{\theta}1}(x + \bar{\theta} \cdot \bar{s} + u) \right).
\]

But, for every \( \bar{s} \in Z^d \) and every \( x \in Z \), by the Hölder Inequality,

\[
\mathbb{E}_{\alpha \in \tilde{Z}_d} \prod_{\bar{\theta} \in \tilde{V}_d} f_{\bar{\theta}1}(x + \bar{\theta} \cdot \bar{s} + u) \leq \prod_{\bar{\theta} \in \tilde{V}_d} \|f_{\bar{\theta}1}\|_{2^d}.
\]

On the other hand, by the induction hypothesis, for every \( x \in Z \),

\[
\mathbb{E}_{\bar{s} \in \tilde{Z}_d} \prod_{\bar{\eta} \in \tilde{V}_d} f_{\bar{\eta}0}(x + \bar{\eta} \cdot \bar{s}) \leq \prod_{\bar{\eta} \in \tilde{V}_d} \|f_{\bar{\eta}0}\|_{2^{d-1}} \leq \prod_{\bar{\eta} \in \tilde{V}_d} \|f_{\bar{\eta}0}\|_{2^d}
\]

and (8) holds for \( d + 1 \). \( \square \)
Corollary 2.4. Let $f_\vec{\varepsilon}, \vec{\varepsilon} \in V_d$, be $2^d$ functions belonging to $L^\infty(\mu)$. Then

\begin{equation}
\left| \mathbb{E}_{x \in \mathbb{Z}, \vec{t} \in \mathbb{Z}^d} \prod_{\vec{\varepsilon} \in V_d} f_\vec{\varepsilon}(x + \vec{\varepsilon} \cdot \vec{t}) \right| \leq \prod_{\vec{\varepsilon} \in V_d} \|f_\vec{\varepsilon}\|_{2^{d-1}}.
\end{equation}

In particular, for $f \in L^\infty(\mu)$,

\begin{equation}
\|f\|_{U(d)} \leq \|f\|_{2^{d-1}}.
\end{equation}

By the corollary, the definition $\| \|$ of the Gowers norm $U(d)$ can be extended by continuity to the space $L^{2^d-1}(\mu)$, and if $f \in L^{2^d-1}(\mu)$, then the integrals defining $\|f\|_{U(d)}$ in Equation $\| \|$ exist and $\| \|$ holds. Using similar reasoning, if $f_\vec{\varepsilon}, \vec{\varepsilon} \in V_d$, are $2^d$ functions belonging to $L^{2^d-1}(\mu)$, then the integral on the left hand side of $\| \|$ exists, Inequality CSG remains valid, and $\| \|$ holds. If we have $2^{d-1}$ functions in $L^{2^d-1}(\mu)$, then Inequality (8) remains valid. Similarly, the definitions and results extend to $D_d f$ and to cubic convolution products for functions belonging to $L^{2^{d-1}}(\mu)$.

The bounds given here (such as $\| \|$) can be improved and made sharp. In particular, one can show that

\[ \|f\|_{U(d)} \leq \|f\|_{2^{d/(d+1)}} \]

and

\[ \|D f\|_\infty \leq \|f\|_{2^{d-1}/(2^{d-1})/d}. \]

We omit the proofs, as they are not used in the sequel.

When $Z$ is infinite, we define the uniform space of level $d$ to be the completion of $L^\infty(\mu)$ under the norm $U(d)$. As $d$ increases, the corresponding uniform spaces shrink. A difficulty is that the uniform space may contain more than just functions. For example, if $Z = \mathbb{T} := \mathbb{R}/\mathbb{Z}$, the uniform space of level 2 consists of the distributions $T$ on $\mathbb{T}$ whose Fourier transform $\hat{T}$ satisfies $\sum_{n \in \mathbb{Z}} |\hat{T}(n)|^4 < +\infty$.

Corollary 2.5. Let $f_\vec{\varepsilon}, \vec{\varepsilon} \in V_d$, be $2^d$ functions on $Z$ and let $\vec{\alpha} \in V_d$. Assume that $f_\vec{\alpha} \in L^1(\mu)$ and $f_\vec{\varepsilon} \in L^{2^d-1}(\mu)$ for $\vec{\varepsilon} \neq \vec{\alpha}$. Then

\[ \left| \mathbb{E}_{x \in \mathbb{Z}, \vec{t} \in \mathbb{Z}^d} \prod_{\vec{\varepsilon} \in V_d} f_\vec{\varepsilon}(x + \vec{\varepsilon} \cdot \vec{t}) \right| \leq \|f_\vec{\alpha}\|_1 \prod_{\vec{\varepsilon} \in V_d, \vec{\varepsilon} \neq \vec{\alpha}} \|f_\vec{\varepsilon}\|_{L^{2^d-1}(\mu)}. \]

Proof. The left hand side is equal to

\[ \left| \int_{Z_d} f_\vec{\alpha}(x_{\vec{\alpha}}) \prod_{\vec{\varepsilon} \in V_d, \vec{\varepsilon} \neq \vec{\alpha}} f_\vec{\varepsilon}(x_{\vec{\varepsilon}}) d\mu_d(x) \right| \]
Using the symmetries of the measure $\mu_d$, we can reduce to the case that $\vec{\alpha} = \vec{0}$, and then the result follows immediately from Lemma 2.3. □

We note for later use:

**Lemma 2.6.** For every $f \in L^{2d-1}(\mu)$, $D_d f(x)$ is a continuous function on $Z$.

More generally, if $f_\vec{\epsilon}, \vec{\epsilon} \in \tilde{V}_d$ are $2^d - 1$ functions belonging to $L^{2d-1}(\mu)$, then the cubic convolution product $D_d(f_\vec{\epsilon}; \vec{\epsilon} \in \tilde{V}_d)(x)$ is a continuous function on $Z$.

*Proof.* By density and (8), it suffices to prove the result when $f_\vec{\epsilon} \in L^\infty(\mu)$ for every $\vec{\epsilon} \in \tilde{V}_d$. Furthermore, we can assume that $|f_\vec{\epsilon}| \leq 1$ for every $\vec{\epsilon} \in \tilde{V}_d$. Let $g$ be the function on $Z$ defined in the statement. For $x, y \in Z$, we have that

$$|g(x) - g(y)| \leq \sum_{\vec{\epsilon} \in \tilde{V}_d} \|f_{\vec{\epsilon}, x} - f_{\vec{\epsilon}, y}\|_1$$

and the result follows. □

### 3. Duality

#### 3.1. Anti-uniform spaces.

Consider the space $L^{2d-1}(\mu)$ endowed with the norm $U(d)$. By (11), the dual of this normed space can be viewed as a subspace of $L^{2d-1}/(2^d-1)(\mu)$, with the duality given by the pairing $\langle \cdot; \cdot \rangle$. Following Green and Tao [3], we define

**Definition 3.1.** The *anti-uniform space of level $d$* is defined to be the dual space of $L^{2d-1}(\mu)$ endowed with the norm $U(d)$. Functions belonging to this space are called *anti-uniform functions of level $d$*. The norm on the anti-uniform space given by duality is called the *anti-uniform norm of level $d$* and is denoted by $\| \cdot \|_{U(d)}^\ast$.

Obviously, when $Z$ is finite, then every function on $Z$ is an anti-uniform function. It follows from the definitions that

$$\|f\|_{U(d+1)}^\ast \leq \|f\|_{U(d)}^\ast$$

for every $f \in L^\infty(Z)$, and thus as $d$ increases, the corresponding anti-uniform spaces increase.

More explicitly, a function $g \in L^{2d-1}/(2^{d-1}-1)(\mu)$ is an anti-uniform function of level $d$ if

$$\sup\{|\langle g; f \rangle|: f \in L^{2d-1}(\mu), \|f\|_{U(d)} \leq 1\} < +\infty$$

and in this case, $\|g\|_{U(d)}^\ast$ is defined to be equal to this supremum. Again, in case of ambiguity about the underlying space $Z$, we write $\| \cdot \|_{U(Z,d)}^\ast$.

We conclude:
Corollary 3.2. For every anti-uniform function $g$ of level $d$, $\|g\|_{U(d)} \geq \|g\|_{L^2/(2d-1)}$.

For $d = 2$, the anti-uniform space consists in functions $g \in L^2(\mu)$ with $\|\hat{g}\|_{L^4/3(2)}$ finite, and for these functions,
\begin{equation}
\|g\|_{U(2)} = \|\hat{g}\|_{L^4/3(2)}.
\end{equation}

From this example, we see that there is no bound for the converse direction of Corollary 3.2.

The dual spaces allow us to give an equivalent reformulation of the Inverse Theorem in terms of dual norms: For each integer $d \geq 1$ and each $\delta > 0$, there exists a family of “$(d-1)$-step nilsequences of bounded complexity,” which we do not define here, such that its convex hull $\mathcal{F}'(d, \delta)$ satisfies

**Inverse Theorem, Dual Form.** For each integer $d \geq 1$ and each $\delta > 0$, every function $g$ on $\mathbb{Z}_N$ with $\|g\|_{U(d)} < 1$ can be written as $g = h + \psi$ with $h \in \mathcal{F}'(d, \delta)$ and $\|\psi\|_1 \leq \delta$.

**Remark 3.3.** In this statement, there is no hypothesis on $\|g\|_\infty$, and the function $g$ is not assumed to be bounded.

**Proof.** We show that this statement is equivalent to the Inverse Theorem. First assume the Inverse Theorem and let $\mathcal{F} = \mathcal{F}(d, \delta)$ be the class of nilsequences and $C = C(d, \delta)$ be as in the formulation of the Inverse Theorem. Let
\[ K = \tilde{\mathcal{F}} + B_{L^1(\mu)}(C), \]

where $\tilde{\mathcal{F}}$ denotes the convex hull of $\mathcal{F}$ and the second term is the ball in $L^1(\mu)$ of radius $C$. Let $g$ be a function with $g \leq C$ on $K$. In particular, $|g| \leq 1$ and $g \leq C$ on $\mathcal{F}$. By the Inverse Theorem, we have that $\|g\|_{U(d)} < \delta$. By the Hahn-Banach Theorem, $K \supset B_{U(d)}(C/\delta)$. Thus
\[ B_{U(d)}(1) \subset (\delta/C)\tilde{\mathcal{F}} + B_{L^1(\mu)}(\delta). \]

Taking $\mathcal{F}'(d, \delta)$ to be $(\delta/C)\tilde{\mathcal{F}}$, we have the statement.

Conversely, we assume the Dual Form and prove the Inverse Theorem. Say that $\mathcal{F}' = \mathcal{F}'(d, \delta/2)$ is the convex hull of $\mathcal{F}_0 = \mathcal{F}_0(d, \delta)$. Assume that $f$ satisfies $|f| \leq 1$ and $\|f\|_{U(d)} \geq \delta$. Then there exists $g$ with $\|g\|_{U(d)} \leq 1$ and $\langle g; f \rangle \geq \delta$. By the dual version, there exists $h \in \mathcal{F}'$ and $\psi$ with $\|\psi\|_1 < \delta/2$ such that $g = h + \psi$. Since
\[ \delta \leq \langle g; f \rangle = \langle h + \psi; f \rangle = \langle h; f \rangle + \langle \psi; f \rangle \]
and $\langle \psi; f \rangle \leq \delta/2$, we have that $\langle h; f \rangle \geq \delta/2$. Since $h \in \mathcal{F}'$, there exists $h' \in \mathcal{F}_0$ with $\langle h'; f \rangle > \delta/2$ and we have the statement. \qed
3.2. Dual functions and anti-uniform spaces.

Lemma 3.4. Let \( f_\bar{c}, \bar{c} \in \tilde{V}_d \), belong to \( L^{2^{d-1}}(\mu) \). Then
\[
\|D_d(f_\bar{c} : \bar{c} \in \tilde{V}_d)\|_{U(d)} \leq \prod_{\bar{c} \in \tilde{V}_d} \|f_\bar{c}\|_{2^{d-1}}.
\]

Proof. For every \( h \in L^{2^{d-1}}(\mu) \), we have that
\[
|\langle h; g \rangle| = \left| \mathbb{E}_{x \in Z, \bar{c} \in \mathcal{Z}} h(x + \bar{c} \cdot \bar{t}) \prod_{\bar{c} \in \tilde{V}_d} f_{\bar{c}}(x + \tilde{c} \cdot \tilde{t}) \right|
\leq \|h\|_{U(d)} \cdot \prod_{\bar{c} \in \tilde{V}_d} \|f_{\bar{c}}\| \leq \|h\|_{U(d)} \cdot \prod_{\bar{c} \in \tilde{V}_d} \|f_{\bar{c}}\|_{2^{d-1}}
\]
by the Cauchy-Schwarz-Gowers Inequality and Inequality (11).

In particular, for \( f \in L^{2^{d-1}}(\mu) \), we have that \( \|D_d f\|_{U(d)} \leq \|f\|_{U(d)}^{2^{d-1}} \).

On the other hand, by (5),
\[
\|f\|_{U(d)}^{2^{d-1}} = \langle D_d f ; f \rangle \leq \|D_d f\|_{U(d)} \cdot \|f\|_{U(d)}
\]
and thus \( \|D_d f\|_{U(d)} \geq \|f\|_{U(d)}^{2^{d-1}} \). We conclude:

Proposition 3.5. For every \( f \in L^{2^{d-1}}(\mu) \), \( \|D_d f\|_{U(d)} = \|f\|_{U(d)}^{2^{d-1}} \).

While the following proposition is not used in the sequel, it gives a helpful description of the anti-uniform space:

Proposition 3.6. The unit ball of the anti-uniform space of level \( d \) is the closed convex hull in \( L^{2^{d-1}/(2^{d-1}-1)}(\mu) \) of the set
\[
\{ D_d f : f \in L^{2^{d-1}}(\mu), \|f\|_{U(d)} \leq 1 \}.
\]

Proof. The proof is a simple application of duality.

Let \( B \subset L^{2^{d-1}/(2^{d-1}-1)}(\mu) \) be the unit ball of the anti-uniform norm \( \|\cdot\|_{U(d)}^* \). Let \( K \) be the convex hull of the set in the statement and let \( \overline{K} \) be its closure in \( L^{2^{d-1}/(2^{d-1}-1)}(\mu) \).

By Proposition 3.5, for every \( f \) with \( \|f\|_{U(d)} \leq 1 \), we have \( D_d f \in B \). Since \( B \) is convex, \( K \subset B \). Furthermore, \( B \) is contained in the unit ball of \( L^{2^{d-1}/(2^{d-1}-1)}(\mu) \) and is a weak* compact subset of this space. Therefore, \( B \) is closed in \( L^{2^{d-1}/(2^{d-1}-1)}(\mu) \) and \( \overline{K} \subset B \).

We check that \( \overline{K} \) is a set. If this does not hold, there exists \( g \in L^{2^{d-1}/(2^{d-1}-1)}(\mu) \) satisfying \( \|g\|_{U(d)}^* \leq 1 \) and \( g \notin \overline{K} \). By the Hahn-Banach Theorem, there exists \( f \in L^{2^{d-1}}(\mu) \) with \( \langle f; h \rangle \leq 1 \) for every \( h \in K \) and \( \langle f; g \rangle > 1 \). This last property implies that \( \|f\|_{U(d)} > 1 \).
Taking $\phi = \|f\|_{U(d)}^{-1} \cdot f$, we have that $\|\phi\|_{U(d)} = 1$ and $\mathcal{D}_d\phi \in K$. Thus by the first property of $f$, $\langle \mathcal{D}_d\phi; f \rangle \leq 1$. But

$$\langle \mathcal{D}_d\phi; f \rangle = \|f\|_{U(d)}^{-2d+1} \langle \mathcal{D}_d f; f \rangle = \|f\|_{U(d)}$$

and we have a contradiction. \(\square\)

It can be shown that when $Z$ is finite, the set appearing in Proposition 3.6 is already closed and convex:

**Proposition 3.7.** Assume $Z$ is finite. Then the set

$$\{ \mathcal{D}_d f : \|f\|_{U(d)} \leq 1 \}$$

is the unit ball of the anti-uniform norm.

We omit the proof of this result, as the proof (for finite $Z$) is similar to that of Theorem 3.8 below, which seems more useful. For the general case, the analogous statement is not as clear because the “uniform space” does not consist only of functions.

### 3.3. Approximation results for anti-uniform functions.

**Theorem 3.8.** Assume $d \geq 1$ is an integer. For every anti-uniform function $g$ with $\|g\|_{U(d)}^* = 1$, integer $k \geq d - 1$, and $\delta > 0$, the function $g$ can be written as

$$g = \mathcal{D}_d f + h,$$

where

$$\|f\|_{2^k} \leq 1/\delta;$$

$$\|h\|_{2^k/(2^k-1)} \leq \delta;$$

$$\|f\|_{U(d)} \leq 1.$$

As in the Dual Form of the Inverse Theorem, there is no hypothesis on $\|g\|_\infty$ and we do not assume that the function $g$ is bounded.

**Proof.** Fix $k \geq d - 1$ and $\delta > 0$. For $f \in L^{2^k}(\mu)$, define

$$\|f\| = \begin{cases} (\|f\|_{U(d)}^2 + \delta^{2^d} \|f\|_{2^d}^2)^{1/2^d} & \text{if } k \geq d; \\ (\|f\|_{U(d)}^2 + \delta^{2^d} \|f\|_{2^{d-1}}^2)^{1/2^d} & \text{if } k = d - 1. \end{cases}$$

Since $\|f\|_{U(d)} \leq \|f\|_{2^{d-1}} \leq \|f\|_{2^d}$ for every $f \in L^{2^k}(\mu)$, $\|f\|$ is well defined on $L^{2^k}(\mu)$ and $\|\cdot\|$ is a norm on this space, equivalent to the norm $\|\cdot\|_{2^k}$.

Let $\|\cdot\|^*$ be the dual norm of $\|\cdot\|$: for $g \in L^{2^k/(2^k-1)}(\mu)$,

$$\|g\|^* = \sup \{ |\langle f; g \rangle| : f \in L^{2^k}(\mu), \|f\| \leq 1 \}.$$
This dual norm is equivalent to the norm $\|\cdot\|_{2/\beta}$ of $L^2$ for every $f \in L^2(\mu)$, we have that
\[ \|g\|^* \leq \|g\|^*_{L^2(\mu)} \text{ for every } g. \]

Fix an anti-uniform function $g$ with $\|g\|^*_{L^2(\mu)} \leq 1$. Since $\|f\| \geq \|f\|_{L^2(\mu)}$ for every $f$, we have that
\[ c := \|g\|^* \leq \|g\|^*_{L^2(\mu)} \leq 1. \]

Set $g' = c^{-1}g$, and so $\|g'\|^* = 1$.

Since the norm $\|\cdot\|$ is equivalent to the norm $\|\cdot\|_{2/\beta}$ and the Banach space $(L^2(\mu), \|\cdot\|_{2/\beta})$ is reflexive, the Banach space $(L^2(\mu), \|\cdot\|)$ is also reflexive. This means that $(L^2(\mu), \|\cdot\|)$ is the dual of the Banach space $(L^2(\mu), \|\cdot\|_{2/\beta})$. Therefore, there exists $f' \in L^2(\mu)$ with
\[ \|f'\| = 1 \text{ and } \langle g'; f' \rangle = 1. \]

By definition (13) of $\|f'\|$,\n\[ \|f'\|_{L^2(\mu)} \leq 1 \text{ and } \|f'\|_{2/\beta} \leq 1/\delta. \]

Assume first that $k \geq d$. (We explain the modifications needed for the case $k = d - 1$ after.)

By (13), (6), and the symmetries of the measure $\mu_\beta$, for every $\phi \in L^2(\mu)$ and every $t \in \mathbb{R}$,
\[ \|f' + t\phi\|_{L^2(\mu)}^2 = \|f'\|_{L^2(\mu)}^2 + 2^dt\langle D_\beta f'; \phi \rangle + o(t), \]
where by $o(t)$ we mean any function such that $o(t)/t \to 0$ as $t \to 0$.

Raising this to the power $2k - d$, we have that
\[ \|f' + t\phi\|_{L^2(\mu)}^{2k} = \|f'\|_{L^2(\mu)}^{2k} + 2^k t\|f'\|_{L^2(\mu)}^{2k-2d} \langle D_\beta f'; \phi \rangle + o(t). \]

On the other hand,
\[ \|f' + t\phi\|_{L^2(\mu)}^{2k} = \|f'\|_{L^2(\mu)}^{2k} + 2^k t\langle f'^{2k-1}; \phi \rangle + o(t). \]

Combining these expressions and using the definition (13) of $\|f' + t\phi\|$ and of $\|f'\|$, we have that
\[ \|f' + t\phi\|^{2k} = \|f' + t\phi\|_{L^2(\mu)}^{2k} + \delta^{2k} \|f' + t\phi\|^{2k}_{L^2(\mu)} \]
\[ = \|f'\|^{2k} + 2^k t\|f'\|_{L^2(\mu)}^{2k-2d} \langle D_\beta f'; \phi \rangle + \delta^{2k} 2^k t\langle f'^{2k-1}; \phi \rangle + o(t) \]
\[ = 1 + 2^k t\|f'\|_{L^2(\mu)}^{2k-2d} \langle D_\beta f'; \phi \rangle + \delta^{2k} 2^k t\langle f'^{2k-1}; \phi \rangle + o(t). \]

Raising this to the power $1/2k$, we have that
\[ \|f' + t\phi\| = 1 + t\|f'\|_{L^2(\mu)}^{2k-2d} \langle D_\beta f'; \phi \rangle + \delta^{2k} t\langle f'^{2k-1}; \phi \rangle + o(t). \]
Since for every \( \phi \in L^2(\mu) \) and every \( t \in \mathbb{R} \) we have
\[
1 + t \langle g'; \phi \rangle = \langle g'; f' + t\phi \rangle \leq \|f' + t\phi\|,
\]
it follows that
\[
1 + t \langle g'; \phi \rangle \leq 1 + t \|f'\|_{U(d)}^{2k-2d} \langle \mathcal{D}_d f'; \phi \rangle + \delta^{2k} t \langle f'^{2k-1}; \phi \rangle + o(t). \]

Since this holds for every \( t \), we have
\[
\langle g'; \phi \rangle = \|f'\|_{U(d)}^{2k-2d} \langle \mathcal{D}_d f'; \phi \rangle + \delta^{2k} \langle f'^{2k-1}; \phi \rangle.
\]

Since this holds for every \( \phi \), we conclude that
\[
g' = \|f'\|_{U(d)}^{2k-2d} \mathcal{D}_d f' + \delta^{2k} f'^{2k-1}. \]

Thus
\[
g = c \|f'\|_{U(d)}^{2k-2d} \mathcal{D}_d f' + c \delta^{2k} f'^{2k-1}.
\]

Set
\[
f = \left( c \|f'\|_{U(d)}^{2k-2d} \right)^{1/(2d-1)} f' \quad \text{and} \quad h = c \delta^{2k} f'^{2k-1}.
\]

Then
\[
g = \mathcal{D}_d f + h
\]

and by (14),
\[
\|f\|_{U(d)} \leq 1; \quad \|f\|_{2^k} \leq 1/\delta
\]
\[
\|h\|_{2^k/(2^k-1)} = c \delta^{2k} \|f'\|_{2^k-1} \leq \delta.
\]

For the case \( k = d - 1 \), for every \( \phi \in L^2(\mu) \) and every \( t \in \mathbb{R} \), we have (15) and
\[
\|f' + t\phi\|_{2^d-1} = \|f'\|_{2^d-1} + 2^d t \|f'\|_{2^d-1} \langle f'^{2d-1-1}; \phi \rangle + o(t).
\]

Thus
\[
\|f' + t\phi\| = 1 + t \langle \mathcal{D}_d f'; \phi \rangle + \delta^{2d} \|f'\|_{2^d-1} \langle f'^{2d-1-1}; \phi \rangle + o(t).
\]

As above, we deduce that
\[
g' = \mathcal{D}_d f' + \delta^{2d} \|f'\|_{2^d-1} f'^{2d-1-1}. \]

Taking
\[
f = c^{1/(2d-1)} f' \quad \text{and} \quad h = c \delta^{2d} \|f'\|_{2^d-1} f'^{2d-1-1},
\]
we have the statement.

\[
\square
\]

When \( Z \) is finite, we can say more:
Theorem 3.9. Assume that $Z$ is finite. Given a function $g$ with $\|g\|_{U(d)}^* = 1$ and $\delta > 0$, the function $g$ can be written as

$$g = D_d f + h,$$

where

$$\|f\|_{\infty} \leq 1/\delta;$$

$$\|h\|_1 \leq \delta;$$

$$\|f\|_{U(d)} \leq 1.$$

Proof. By Theorem 3.8 for every $k \geq d - 1$ we can write

$$g = D_d f_k + h_k,$$

where

$$\|f_k\|_{2^k} \leq 1/\delta; \|h_k\|_{2^k/(2^k-1)} \leq \delta; \|f_k\|_{U(d)} \leq 1.$$

Let $N = |Z|$. Since $\|f_k\|_{2^k} \leq 1/\delta$, we have that $\|f_k\|_{\infty} \leq N/\delta$. In the same way, $\|h_k\|_{\infty} \leq N\delta$. By passing to a subsequence, since the functions are uniformly bounded we can therefore assume that $f_k \to f$ and that $h_k \to h$ pointwise as $k \to +\infty$. Thus $D_d f_k \to D_d f$ pointwise and so

$$g = D_d f + h.$$

Since $\|f_k\|_{U(d)} \to \|f\|_{U(d)}$, it follows that $\|f\|_{U(d)} \leq 1$. For every $k \geq d - 1$, we have that $\|h_k\|_1 \leq \|h_k\|_{2^k/(2^k-1)} \leq \delta$. Since $\|h_k\|_1 \to \|h\|_1$, it follows that $\|h\|_1 \leq \delta$. For $\ell \geq k \geq d - 1$,

$$\|f\|_{2^k} \leq \|f\|_{2^\ell} \leq 1/\delta.$$

Taking the limit as $\ell \to +\infty$, we have that $\|f\|_{2^k} \leq 1/\delta$ for every $k \geq d - 1$ and so $\|f\|_{\infty} \leq 1/\delta$. □

Question 3.10. Does Theorem 3.9 also hold when $Z$ is infinite?

We conjecture that the answer is positive, but the proof given does not carry through to this case.

3.4. Applications. Theorems 3.8 and 3.9 give insight into the $U(d)$ norm, connecting it to the classical $L^p$ norms. For example, we have:

Corollary 3.11. Let $\phi$ be a function with $\|\phi\| \leq 1$ and $\|\phi\|_{U(d)} = \theta > 0$. Then for every $p \geq 2^{d-1}$, there exists a function $f$ such that $\|f\|_p \leq 1$ and $\langle D_d f; \phi \rangle > (\theta/2)^{2^d}$.

If $Z$ is finite, there exists a function $f$ with $\|f\|_{\infty} \leq 1$ and $\langle D_d f; \phi \rangle > (\theta/2)^{2^d}$. 
Proof. It suffices to prove the result when \( p = 2^k \) for some integer \( k \geq d - 1 \). There exists \( g \) with \( \|g\|_{U(d)}^* = 1 \) and \( \langle g; \phi \rangle = \theta \). Taking \( \delta = \theta/2 \) in Theorem 3.8, we have the first statement. For the second statement, apply Theorem 3.9. □

Theorem 3.9 leads to an equivalent reformulation of the Inverse Theorem, without any explicit reference to the Gowers norms. For all \( d \geq 1 \) and \( \delta > 0 \), there exists a family of “\((d-1)\)-step nilsequences of bounded complexity” whose convex hull \( F''(d, \delta) \) satisfies:

**Inverse Theorem, Reformulated Version.** For every \( \delta > 0 \), every function \( \phi \) on \( \mathbb{Z}_N \) with \( \|\phi\|_\infty \leq 1 \), the function \( \mathcal{D}_d \phi \) can be written as \( \mathcal{D}_d \phi = g + h \) with \( g \in F''(d, \delta) \) and \( \|h\|_1 \leq \delta \).

Proof. We show that the statement is equivalent to the Dual Form of the Inverse Theorem. First assume the Dual Form. Given \( \phi \) with \( \|\phi\|_\infty \leq 1 \), we have that \( \|\phi\|_{U(d)} \leq 1 \) and thus \( \|\mathcal{D}_d \phi\|_{U(d)} \leq 1 \). By the Dual Form, \( \mathcal{D}_d \phi = h + \psi \), where \( h \in F'(d, \delta) \) and \( \|\psi\|_1 \leq \delta \), which is exactly the Reformulated Version.

Conversely, assume the Reformulated Version. Let \( g \in B_{U(d)}^*(1) \). Then by Theorem 3.8, \( g = \mathcal{D}_d h + \psi \), where \( \|h\|_\infty \leq 2/\delta \) and \( \|\psi\|_1 \leq \delta/2 \). Define \( F' = F'(d, \delta) \) to be equal to \( (2/\delta)^{2d-1} F''(d, \eta) \), where \( \eta \) is a positive constant to be defined later and \( F''(d, \eta) \) is as in the Reformulated Version. By the Reformulated Version, \( \mathcal{D}_d h = f + \psi \), with \( f \in F' \) and \( \|\psi\|_1 \leq (2/\delta)^{2d-1} \eta \).

Then \( g = f + \phi + \psi \) with \( f \in F' \) and \( \|\phi + \psi\|_1 \leq \delta/2 + (2/\delta)^{2d-1} \eta \). Taking \( \eta = (\delta/2)^{2d} \), we have the result. □

3.5. **Anti-uniformity norms and embeddings.** This section is a conjectural, and somewhat optimistic, exploration of the possible uses of the theory of anti-uniform norms we have developed. The main interest is not the sketches of proofs included, but rather the questions posed and the directions that we conjecture may be approached using these methods.

**Definition 3.12.** If \( G \) is a \((d-1)\)-step nilpotent Lie group and \( \Gamma \) is a discrete, cocompact subgroup of \( G \), the compact manifold \( X = G/\Gamma \) is \((d-1)\)-step nilmanifold. The natural action of \( G \) on \( X \) by left translations is written as \( (g, x) \mapsto g.x \) for \( g \in G \) and \( x \in X \).

We recall the following “direct” result (a converse to the Inverse Theorem), proved along the lines of arguments in [8]:

\[ \text{(Direct Result)} \]
Proposition 3.13 (Green and Tao (Proposition 12.6, [4])). Let \( X = G/\Gamma \) be a \( (d-1) \)-step nilmanifold, \( x \in X, \ g \in G, \ F \) be a continuous function on \( X \), and \( N \geq 2 \) be an integer. Let \( f \) be a function on \( \mathbb{Z}_N \) with \(|f| \leq 1\). Assume that for some \( \eta > 0 \),
\[
|E_{n<N} f(n) F(g^n \cdot x)| \geq \eta.
\]
Then there exists a constant \( c = c(X, F, \eta) > 0 \) such that
\[
\|f\|_{U(d)} \geq c.
\]

The key point is that the constant \( c \) depends only on \( X, F, \) and \( \eta \), and not on \( f, N, g \) or \( x \).

Remark 3.14. In [4], the average is taken over the interval \([-N/2, N/2]\) instead of \([0, N)\), but the proof of Proposition 3.13 is the same for the modified choice of interval.

A similar result is given in Appendix G of [6], and proved using simpler methods, but there the conclusion is about the norm \( \|f\|_{U(d, \mathbb{Z}_{N'})} \), where \( N' \) is sufficiently large with respect to \( N \).

By duality, Proposition 3.13 can be rewritten as

\textbf{Proposition 3.15.} Let \( X = G/\Gamma, x, g, F \) be as in Proposition 3.13. Let \( N \geq 2 \) be an integer and let \( h \) denote the function \( n \mapsto F(g^n \cdot x) \) restricted to \([0, N)\) and considered as a function on \( \mathbb{Z}_N \). Then for every \( \eta > 0 \), we can write
\[
h = \phi + \psi
\]
where \( \phi \) and \( \psi \) are functions on \( \mathbb{Z}_N \) with \( \|\phi\|_{U(d)}^* \leq c(X, F, \eta) \) and \( \|\psi\|_1 \leq \eta \).

Proposition 3.13 does not imply that \( \|h\|_{U(d)}^* \) is bounded independent of \( N \), and using (12), one can easily construct a counterexample for \( d = 2 \) and \( X = \mathbb{T} \). On the other hand, for \( d = 2 \) we do have that \( \|h\|_{U(d)}^* \) is bounded independent of \( N \) when the function \( F \) is sufficiently smooth. Recalling that the Fourier series of a continuously differentiable function on \( \mathbb{T} \) is absolutely convergent and directly computing using Fourier coefficients, we have:

\textbf{Proposition 3.16.} Let \( F \) be a continuously differentiable function on \( \mathbb{T} \) and let \( \alpha \in \mathbb{T} \). Let \( N \geq 2 \) be an integer and let \( h \) denote the restriction of the function \( n \mapsto F(\alpha^n) \) to \([0, N)\), considered as a function on \( \mathbb{Z}_N \). Then
\[
\|h\|_{U(2)}^* \leq c \|\hat{F}\|_{\ell^1(\mathbb{Z})},
\]
where \( c \) is a universal constant.
A similar result holds for functions on $T^k$.

It is natural to ask whether a similar result holds for $d > 2$. For the remained of this section, we assume that every nilmanifold $X$ is endowed with a smooth Riemannian metric. For $k \geq 1$, we let $C^k(X)$ denote the space of $k$-times continuously differentiable functions on $X$, endowed with the usual norm $\| \cdot \|_{C^k(X)}$. We ask if the dual norm is bounded independent of $N$:

**Question 3.17.** Let $X = G/\Gamma$ be a $(d-1)$-step nilmanifold. Does there exist an integer $k \geq 1$ and a positive constant $c$ such that for all choices of a function $F \in C^k(X)$, $g \in G$, $x \in X$ and integer $N \geq 2$, writing $h$ for the restriction to $[0,N)$ of the function $n \mapsto F(g^n \cdot x)$, considered as a function on $\mathbb{Z}_N$, we have

$$\|h\|_{U(d)}^* \leq c\|F\|_{C^k(X)}?$$

**Definition 3.18.** If $g \in G$ and $x \in X$ are such that $g^N \cdot x = x$, we say that the map $n \mapsto g^n \cdot x$ is an embedding of $\mathbb{Z}_N$ in $X$.

**Proposition 3.19.** The answer to Question 3.17 is positive under the additional hypothesis that $n \mapsto g^n \cdot x$ is an embedding of $\mathbb{Z}_N$ in $X$, that is, that $g^N \cdot x = x$.

The proof of this proposition is similar to that of Proposition 5.6 in [9] and so we omit it.

More generally, we can phrase these results and the resulting question for groups other than $\mathbb{Z}_N$. We restrict ourselves to the case of $T$, as the extension to $T^k$ is clear. By the same argument used for Proposition 3.13, we have:

**Proposition 3.20.** Let $X = G/\Gamma$ be a $(d-1)$-step nilmanifold, $x \in X$, $u$ be an element in the Lie algebra of $G$, and $F$ be a continuous function on $X$. Let $f$ be a function on $T$ with $|f| \leq 1$. Assume that for some $\eta > 0$ we have

$$\left| \int f(t)F(\exp(\text{t}u) \cdot x) \, dt \right| \geq \eta,$$

where we identify $T$ with $[0,1)$ in this integral. Then there exists a constant $c = c(X, F, \eta) > 0$ such that

$$\|f\|_{U(d)} \geq c.$$

By duality, Proposition 3.20 can be rewritten as

**Proposition 3.21.** Let $X = G/\Gamma, x, u, F$, and $c = c(X, F, \eta)$ be as in Proposition 3.20. Let $h$ denote the restriction of the function $t \mapsto$
then for every \( \eta > 0 \), we can write
\[
h = \phi + \psi,
\]
where \( \phi \) and \( \psi \) are functions on \( \mathbb{T} \) with \( \| \phi \|_{U(d)} \leq c \) and \( \| \psi \|_1 \leq \eta \).

We can ask the analog of Question 3.17 for the group \( \mathbb{T} \):

**Question 3.22.** Let \( X = G/\Gamma \) be a \( (d-1) \)-step nilmanifold. Does there exist an integer \( k \geq 1 \) and a positive constant \( c \) such that for all choices of a function \( F \in C^k(X) \), \( u \) in the Lie algebra of \( G \), and \( x \in X \), writing \( h \) for the restriction of the function \( t \mapsto F(\exp(tu) \cdot x) \) to \([0,1)\), considered a function on \( \mathbb{T} \), we have
\[
\|h\|_{U(d)} \leq c\|F\|_{C^k(X)}?
\]

Analogous to Proposition 3.19, the answer to this question is positive under the additional hypothesis that \( t \mapsto \exp(tu) \cdot x \) is an embedding of \( \mathbb{T} \) in \( X \), meaning that \( \exp(u) \cdot x = x \).

### 4. Multiplicative structure

#### 4.1. Higher order Fourier Algebras.

In light of Theorem 3.8, the family of functions \( g \) on \( \mathbb{Z} \) of the form \( g = D_d f \) for \( f \in L^{2^k}(\mu) \) for some \( k \geq d - 1 \) is relevant, and more generally, cubic convolution products for functions \( f_\vec{e}, \vec{e} \in \hat{V}_d \), belonging to \( L^{2^k}(\mu) \) for some \( k \geq d - 1 \). We only consider the case \( k = d - 1 \), as it gives rise to interesting algebras.

**Definition 4.1.** For an integer \( d \geq 1 \), define \( A(d) \) to be the space of functions \( g \) on \( \mathbb{Z} \) that can be written as
\[
g(x) = \sum_{j=1}^{\infty} D_d(f_{j,\vec{e}}; \vec{e} \in \hat{V}_d)
\]
where all the functions \( f_{j,\vec{e}} \) belong to \( L^{2^{d-1}}(\mu) \) and
\[
\sum_{j=1}^{\infty} \prod_{\vec{e} \in \hat{V}_d} \| f_{j,\vec{e}} \|_{2^{d-1}} < +\infty.
\]

For \( g \in A(d) \), we define
\[
\|g\|_{A(d)} = \inf \sum_{j=1}^{\infty} \prod_{\vec{e} \in \hat{V}_d} \| f_{j,\vec{e}} \|_{2^{d-1}},
\]
where the infimum is taken over all families of functions \( f_{j,\vec{e}} \) in \( L^{2^{d-1}}(\mu) \) satisfying (16) and (17).
We call $A(d)$ the Fourier algebra of order $d$; we show in this section that it is a Banach algebra.

It follows from the definitions that $A(1)$ consists of the constant functions with the norm $\|\cdot\|_{A(1)}$ being absolute value. Clearly, if $Z$ is finite and $d \geq 2$, then every function on $Z$ belongs to $A(d)$ and we can replace each series by a finite sum in the definitions.

It is easy to check that $A(d)$ is a vector space of functions.

Furthermore, by (8) and Lemma 2.6, condition (17) implies that the series in (16) converges under the uniform norm and that every function in $A(d)$ is a continuous function on $Z$. Moreover, by (8), $\|g\|_\infty \leq \|g\|_{A(d)}$ and $\|\cdot\|_{A(d)}$ is a norm on $A(d)$.

For every $g \in A(d)$, we have that $g$ belongs to that anti-uniform space of level $d$ and that $\|g\|_{\hat{U}(d)} \leq \|g\|_{A(d)}$.

If $(g_n)_{n \in \mathbb{N}}$ is a sequence in $A(d)$ with $g = \sum_{n=1}^{\infty} g_n$ in $A(d) < +\infty$, then the series $\sum_{n=1}^{\infty} g_n$ converges under the uniform norm, the sum $g$ of this series belongs to $A(d)$, and the series converges to $g$ in $A(d)$. This shows that the space $A(d)$ endowed with the norm $\|\cdot\|_{A(d)}$ is a Banach space.

Let $C(Z)$ denote the space of continuous functions on $Z$. We summarize:

**Proposition 4.2.** $A(d)$ is a linear subspace of $C(Z)$ and of the anti-uniform space of level $d$. For every $g \in A(d)$, we have that $\|g\|_\infty \leq \|g\|_{A(d)}$. The space $A(d)$ endowed with the norm $\|\cdot\|_{A(d)}$ is a Banach space.

4.2. Tao’s uniform almost periodicity norms. In [13], Tao introduced a sequence of norms, the uniform almost periodicity norms, that also play a dual role to the Gowers uniformity norms:

**Definition 4.3** (Tao [13]). For $f : Z \to \mathbb{C}$, define $\|f\|_{UAP^d(Z)}$ to be equal to $|c|$ if $f$ is equal to the constant $c$, and to be infinite otherwise. For $d \geq 1$, define $\|f\|_{UAP^{d+1}(Z)}$ to be the infimum of all constants $M > 0$ such that for all $n \in \mathbb{Z},$

$$T^n f = M \mathbb{E}_{h \in H}(c_{n,h} g_h),$$

for some finite nonempty set $H$, collection of functions $(g_h)_{h \in H}$ from $Z$ to $\mathbb{C}$ satisfying $\|g_h\|_{L^\infty(Z)} \leq 1$, collection of functions $(c_{n,h})_{n \in \mathbb{Z}, h \in H}$ from $Z$ to $\mathbb{C}$ satisfying $\|c_{n,h}\|_{UAP^d(Z)} \leq 1$, and a random variable $h$ taking values in $H$.

When the underlying group is clear, we omit it from the notation and write $\|f\|_{UAP^d(Z)} = \|f\|_{UAP^d}$. 

Remark 4.4. The definition given in [13] implicitly assumes that $Z$ is finite; to extend to the case that $Z$ is infinite, take $H$ to be an arbitrary probability space and view the functions $g_h$ and $c_{n,h}$ as random variables.

Tao shows that this defines finite norms $\text{UAP}^d$ for $d \geq 1$ and that the uniformly almost periodic functions of order $d$ (meaning functions for which the $\text{UAP}^d$ norm is bounded) form a Banach algebra:

$$\|fg\|_{\text{UAP}^d} \leq \|f\|_{\text{UAP}^d} \|g\|_{\text{UAP}^d}.$$ 

The $\text{UAP}^{d-1}$ and $A(d)$ norms are related: both are algebra norms and they satisfy similar properties, such as

$$\|f\|_{\text{UAP}^{d-1}} \geq \|f\|_{U(d)}^*$$

and

$$\|f\|_{A(d)} \geq \|f\|_{U(d)}^*.$$ 

For $d = 2$, the two norms are in fact the same (an exercise in [14] due to Green and Section 4.3 below). However, in general we do not know if they are equal:

Question 4.5. For a function $f : Z \to \mathbb{C}$, is

$$\|f\|_{A(d)} = \|f\|_{\text{UAP}^{d-1}}$$

for all $d \geq 2$?

In particular, while the UAP norms satisfy

$$\|f\|_{\text{UAP}(d-1)} \geq \|f\|_{\text{UAP}(d)}$$

for all $d \geq 2$, we do not know if the same inequality holds for the norms $A(d)$.

4.3. The case $d = 2$. We give a further description for $d = 2$, relating these notions to the classical objects in Fourier analysis.

We have that $\widetilde{V}_2 = \{01, 10, 11\}$. Every function $g$ defined as a cubic convolution product of $f_{\vec{e}}$, $\vec{e} \in \widetilde{V}_2$, satisfies

$$\sum_{\xi \in \hat{Z}} |\hat{g}(\xi)|^{2/3} = \sum_{\xi \in \hat{Z}} \prod_{\vec{e} \in \widetilde{V}_2} |\hat{f}_{\vec{e}}(\xi)|^{2/3}$$

$$\leq \prod_{\vec{e} \in \widetilde{V}_2} \left( \sum_{\xi \in \hat{Z}} |\hat{f}_{\vec{e}}(\xi)|^2 \right)^{1/3} = \prod_{\vec{e} \in \widetilde{V}_2} \|f_{\vec{e}}\|_{L^2(\mu)}^{2/3}.$$ 

Thus

$$\sum_{\xi \in \hat{Z}} |\hat{g}(\xi)| \leq \prod_{\vec{e} \in \widetilde{V}_2} \|f_{\vec{e}}\|_{L^2(\mu)}.$$
It follows that for $g \in A(d)$, we have that

$$\sum_{\xi \in \hat{Z}} |\hat{g}(\xi)| \leq \|g\|_{A(2)}.$$ 

On the other hand, let $g$ be a continuous function on $Z$ with $\sum_{\xi \in \hat{Z}} |\hat{g}(\xi)| < +\infty$. This function can be written as (in this example, we make an exception to our convention that all functions are real-valued)

$$g(x) = \sum_{\xi \in \hat{Z}} \hat{g}(\xi) \xi(x) = \sum_{\xi \in \hat{Z}} \hat{g}(\xi) \mathbb{E}_{t_1, t_2 \in Z} \xi(x + t_1) \xi(x + t_2) \xi(x + t_1 + t_2).$$

It follows that $g \in A(d)$ and $\|g\|_{A(2)} \leq \sum_{\xi \in \hat{Z}} |\hat{g}(\xi)|$.

We summarize these calculations:

**Proposition 4.6.** The space $A(2)$ coincides with the Fourier algebra $A(Z)$ of $Z$:

$$A(Z) := \{ g \in C(Z) : \sum_{\xi \in \hat{Z}} |\hat{g}(\xi)| < +\infty \}$$

and, for $g \in A(Z)$, $\|g\|_{A(2)} = \|g\|_{A(Z)}$, which is equal by definition to the sum of this series.

4.4. $A(d)$ is an algebra of functions.

**Theorem 4.7.** The Banach space $A(d)$ is invariant under pointwise multiplication and $\|\cdot\|_{A(d)}$ is an algebra norm, meaning that for all $g, g' \in A(d)$,

$$\|gg'\|_{A(d)} \leq \|g\|_{A(d)} \|g'\|_{A(d)}.$$  

**Proof.** Assume that

$$g(x) = D_d(f_{\vec{c}}; \vec{c} \in V_d)(x) \quad \text{and} \quad g'(x) = D_d(f'_{\vec{c}}; \vec{c} \in V_d)(x),$$

where $f_{\vec{c}}$ and $f'_{\vec{c}} \in L^{2^{d-1}}(\mu)$ for every $\vec{c} \in V_d$. Once we show that $gg' \in A(d)$ and

$$\|gg'\|_{A(d)} \leq \prod_{\vec{c} \in V_d} \|f_{\vec{c}}\|_{2^{d-1}} \|f'_{\vec{c}}\|_{2^{d-1}},$$

the statement of the theorem follows from the definitions of the space $A(d)$ and its norm.

We have

$$g(x)g'(x) = \mathbb{E}_{\vec{c} \in V_d} \left( \mathbb{E}_{\vec{c} \in V_d} \prod_{\vec{t} \in V_d} f_{\vec{c}}(x + \vec{c} \cdot \vec{t}) f'_{\vec{c}}(x + \vec{c} \cdot \vec{s}) \right)$$
Writing \( \vec{u} = \vec{s} - \vec{t} \), we have that

\[
g(x)g'(x) = \mathbb{E}_{\vec{u} \in Z^d} \left( \mathbb{E}_{\vec{t} \in V_d} \prod_{\vec{u} \in V_d} f_{\vec{t}}(x + \vec{e} \cdot \vec{t}) f'_{\vec{t}}(x + \vec{e} \cdot \vec{u} + \vec{e} \cdot \vec{t}) \right)
\]

\[
= \mathbb{E}_{\vec{u} \in Z^d} \left( \mathbb{E}_{\vec{t} \in V_d} \prod_{\vec{t} \in V_d} (f_{\vec{t}} \cdot f'_{\vec{t},c\vec{a}})(x + \vec{e} \cdot \vec{t}) \right) = \mathbb{E}_{\vec{u} \in Z^d} g^{(\vec{u})}(x),
\]

where

\[
g^{(\vec{u})}(x) := \mathbb{E}_{\vec{t} \in V_d} \prod_{\vec{t} \in V_d} (f_{\vec{t}} \cdot f'_{\vec{t},c\vec{a}})(x + \vec{e} \cdot \vec{t}).
\]

Then

\[
\mathbb{E}_{\vec{u} \in Z^d} \prod_{\vec{t} \in V_d} \|f_{\vec{t}} \cdot f'_{\vec{t},c\vec{a}}\|_2^{d-1}
\]

\[
= \mathbb{E}_{u_1, \ldots, u_{d-1} \in Z} \left( \prod_{\vec{t} \in V_d} \|f_{\vec{t}} \cdot f'_{\vec{t},c\vec{a}}\|_2^{d-1} \right)
\]

\[
= \prod_{\vec{t} \in V_d} \mathbb{E}_{u \in Z} \|f_{\vec{t}} \cdot f'_{\vec{t},c\vec{a}}\|_2^{d-1} \leq \prod_{\vec{t} \in V_d} \mathbb{E}_{u \in Z} \|f_{\vec{t}} \cdot f'_{\vec{t},c\vec{a}}\|_2^{d-1}.
\]

But, for all \( u_1, u_2, \ldots, u_{d-1} \in Z \) and every \( \vec{c} \in \tilde{V}_d \) with \( \epsilon_d = 1 \),

\[
\mathbb{E}_{u \in Z} \|f_{\vec{t}} \cdot f'_{\vec{t},c\vec{a}}\|_2^{d-1} = \|f_{\vec{t}}\|_2^{d-1} \|f'_{\vec{t}}\|_2^{d-1}.
\]

On the other hand,

\[
\mathbb{E}_{u_1, \ldots, u_{d-1} \in Z} \prod_{\vec{t} \in V_d} \|f_{\vec{t}} \cdot f'_{\vec{t},c\vec{a}}\|_2^{d-1}
\]

\[
\leq \prod_{\vec{t} \in V_d} \mathbb{E}_{u_1, \ldots, u_{d-1} \in Z} \|f_{\vec{t}} \cdot f'_{\vec{t},c\vec{a}}\|_2^{d-1}.
\]

But, for \( \vec{c} \in \tilde{V}_d \) with \( \epsilon_d = 0 \), we have that \( \epsilon_1, \ldots, \epsilon_{d-1} \) are not all equal to 0 and

\[
\mathbb{E}_{u_1, \ldots, u_{d-1} \in Z} \|f_{\vec{t}} \cdot f'_{\vec{t},c\vec{a}}\|_2^{d-1} = \mathbb{E}_{u \in Z} \|f_{\vec{t}}\|_2^{d-1} \|f'_{\vec{t}}\|_2^{d-1}.
\]
Combining these relations, we obtain that
\[ E_{\vec{u} \in Z^d} \prod_{\vec{e} \in V_d} \| f \cdot f'_{\vec{e},\vec{u}} \|_{2^{d-1}} \leq \prod_{\vec{e} \in V_d} \| f_{\vec{e}} \|_{2^{d-1}} \| f'_\vec{e} \|_{2^{d-1}}. \]

Therefore, for \( \mu \times \cdots \times \mu \)-almost every \( \vec{u} \in Z^d \) and for every \( \vec{e} \in \tilde{V}_d \), the function \( f_{\vec{e}} f'_{\vec{e},\vec{u}} \) belongs to \( L^{2^{d-1}}(\mu) \). It follows that for \( \mu \times \cdots \times \mu \)-almost every \( \vec{u} \in Z^d \), the function \( g^{(\vec{u})} \) belongs to \( A(d) \) and that
\[ E_{\vec{u} \in Z^d} \| g^{(\vec{u})} \|_{A(d)} \leq \prod_{\vec{e} \in V_d} \| f_{\vec{e}} \|_{2^{d-1}} \| f'_\vec{e} \|_{2^{d-1}}. \]

Since \( gg'(x) = E_{\vec{u} \in Z^d} g^{(\vec{u})}(x) \), Inequality (21) follows. \( \square \)

4.5. Decomposable functions on \( Z_d \). Recall that \( Z_d \) is the subset of \( Z^{2^d} \) defined in (2) and the elements \( x \in Z_d \) are written as \( x = (x_{\vec{e}} : \vec{e} \in V_d) \).

Definition 4.8. The space \( D(d) \) of decomposable functions consists in functions \( F \) on \( Z_d \) that can be written as
\[ F(x) = \sum_{j=1}^{\infty} \prod_{\vec{e} \in V_d} f_{j,\vec{e}}(x_{\vec{e}}), \]
where all the functions \( f_{j,\vec{e}} \) belong to \( L^{2^d}(\mu) \) and
\[ \sum_{j=1}^{\infty} \prod_{\vec{e} \in V_d} \| f_{j,\vec{e}} \|_{L^{2^d}(\mu)} < +\infty. \]

For \( F \in D(d) \), define
\[ \| F \|_{D(d)} = \inf \sum_{j=1}^{\infty} \prod_{\vec{e} \in V_d} \| f_{j,\vec{e}} \|_{2^d}, \]
where the infimum is taken over all families of functions \( f_{j,\vec{e}} \) in \( L^{2^d}(\mu) \) satisfying (22) and (23).

By the remark following (11), a function \( F \in D(d) \) belongs to \( L^2(\mu_d) \) and
\[ \| F \|_{L^2(\mu_d)} \leq \| F \|_{D(d)}. \]

Clearly, if \( Z \) is finite, then every function on \( Z_d \) belongs to \( D(d) \) and in the definition, we can replace the series by a finite sum.

We summarize the properties of the space \( D(d) \):

Proposition 4.9. \( D(d) \) is a linear subspace of \( L^2(\mu_d) \) and for \( F \in D(d) \), we have that \( \| F \|_{L^2(\mu_d)} \leq \| F \|_{D(d)} \). The space \( D(d) \) endowed with the norm \( \| \cdot \|_{D(d)} \) is a Banach space.
4.6. Diagonal translations.

**Definition 4.10.** For $t \in \mathbb{Z}$, we write $t^\Delta = (t, t, \ldots, t) \in \mathbb{Z}^d$. The map $x \mapsto x + t^\Delta$ is called the **diagonal translation by** $t$.

Let $\mathcal{I}(d)$ denote the subspace of $L^2(\mu_d)$ consisting of functions invariant under all diagonal translations. The orthogonal projection $\pi$ on $\mathcal{I}(d)$ is given by

$$\pi F(x) = \mathbb{E}_{t \in \mathbb{Z}} F(x + t^\Delta).$$

**Proposition 4.11.** If $F$ belongs to $D(d)$, then $\pi F$ belongs to $D(d)$ and $\|\pi F\|_{D(d)} \leq \|F\|_{D(d)}$. Furthermore, $\pi F$ is a continuous function on $\mathbb{Z}^d$ satisfying $\|\pi F\|_{\infty} \leq \|F\|_{D(d)}$.

In particular, functions $F$ belonging to $D(d) \cap \mathcal{I}(d)$ are continuous on $\mathbb{Z}^d$ and satisfy $\|F\|_{\infty} \leq \|F\|_{D(d)}$.

**Proof.** Assume that $f$ is given by (22) where the functions $f_{\vec{v}, t}$ belong to $L^2(\mu)$ for every $\vec{v} \in \mathbb{V}_d$. Then

$$\pi F(x) = \mathbb{E}_{t \in \mathbb{Z}} \prod_{j=1}^{\infty} f_{\vec{v}_{\vec{e}}, t}(x_{\vec{e}}).$$

The first equality gives the first part of the proposition and the second implies the second part. \qed

**Theorem 4.12.** For $F \in D(d)$ and $G \in D(d) \cap \mathcal{I}(d)$, we have that $FG$ belongs to $D(d)$ and that $\|FG\|_{D(d)} \leq \|F\|_{D(d)} \|G\|_{D(d)}$.

In particular, $D(d) \cap \mathcal{I}(d)$, endowed with pointwise multiplication and the norm $\|\cdot\|_{B(d)}$, is a Banach algebra.

**Proof.** Since $\pi G = G$ when $G \in D(d) \cap \mathcal{I}(d)$, it suffices to show that for all $F, G \in D(d)$, we have $F.\pi G \in D(d)$ and

$$\|F.\pi G\|_{D(d)} \leq \|F\|_{D(d)} \|G\|_{D(d)}.$$  

(24)

First consider the case that $F$ and $G$ are product function:

$$F(x) = \prod_{\vec{e} \in \mathbb{V}_d} f_{\vec{v}, x_{\vec{e}}}, \quad G(x) = \prod_{\vec{e} \in \mathbb{V}_d} g_{\vec{v}, x_{\vec{e}}},$$

where $f_{\vec{v}}$ and $g_{\vec{v}} \in L^2(\mu)$ for every $\vec{v} \in \mathbb{V}_d$. Then

$$(F.\pi G)(x) = \mathbb{E}_{t \in \mathbb{Z}} \prod_{\vec{e} \in \mathbb{V}_d} (f_{\vec{v}, t}g_{\vec{v}, t})(x_{\vec{e}}) = E_{t \in \mathbb{Z}} H(t)(x),$$
where
\[
H^{(t)}(x) \prod_{\tilde{e} \in \tilde{V}_d} (f_{\tilde{e}} \cdot g_{\tilde{c}_t})(x_{\tilde{e}}).
\]
Furthermore,
\[
\mathbb{E}_{t \in Z} \prod_{\tilde{e} \in \tilde{V}_d} \|f_{\tilde{e}} \cdot g_{\tilde{c}_t}\|_{2^d} \leq \prod_{\tilde{e} \in \tilde{V}_d} \left( \mathbb{E}_{t \in Z} \|f_{\tilde{e}} \cdot g_{\tilde{c}_t}\|_{2^d}^2 \right)^{1/2^d} = \prod_{\tilde{e} \in \tilde{V}_d} \|f_{\tilde{e}}\|_{2^d} \|g_{\tilde{c}_t}\|_{2^d}.
\]
Thus for \(\mu\)-almost every \(t \in Z\), we have that \(f_{\tilde{e}} \cdot g_{\tilde{c}_t}\) belongs to \(L^{2^d}\) for every \(\tilde{e}\) and the function \(H^{(t)}\) belongs to \(B(d)\). Finally,
\[
\|F \cdot \pi G\|_{B(d)} \leq E_{t \in Z} \|H^{(t)}\|_{B(d)} \leq E_{t \in Z} \prod_{\tilde{e} \in \tilde{V}_d} \|f_{\tilde{e}}\|_{2^d} \|g_{\tilde{e}}\|_{2^d}
\]
and the statement of the theorem follows from the definitions of the space \(D(d)\) and its norm. \(\square\)

5. A RESULT OF FINITE APPROXIMATION

5.1. A decomposition theorem. For a probability space \((X, \mu)\), we assume throughout that it belongs to one of the two following classes:

- \(\mu\) is nonatomic. We refer to this case as the infinite case.
- \(X\) is finite and \(\mu\) is the uniform probability measure on \(X\). We refer to this case as the finite case.

This is not a restrictive assumption: Haar measure on a compact abelian group always falls into one of these two categories.

As usual, all subsets or partitions of \(X\) are implicitly assumed to be measurable.

**Definition 5.1.** Let \(m \geq 2\) be an integer and let \((X_1, \ldots, X_m)\) a partition of the probability space \((X, \mu)\). This partition is **almost uniform** if:

- in the infinite case, \(\mu(X_i) = 1/m\) for every \(i\).
- In the finite case, \(|X_i| = |X|/m\) or \(|X|/m\) for every \(i\).

The main result of this paper is:

**Theorem 5.2.** Let \(d \geq 1\) be an integer and let \(\delta > 0\). There exists an integer \(M = M(d, \delta) \geq 2\) and a constant \(C = C(d, \delta) > 0\) such that the following holds: if \(f_{\tilde{e}}, \tilde{c} \in \tilde{V}_{d+1}\), are \(2^{d+1} - 1\) functions belonging to \(L^{2^d}(\mu)\) with \(\|f_{\tilde{e}}\|_{L^{2^d}(\mu)} \leq 1\) and
\[
\phi(x) = D_{d+1}(f_{\tilde{e}}; \tilde{c} \in \tilde{V}_{d+1})(x),
\]
then for every \( \delta > 0 \) there exist an almost uniform partition \((X_1, \ldots, X_m)\) of \( Z \) with \( m \leq M \) sets, a nonnegative function \( \rho \) on \( Z \), and for \( 1 \leq i \leq m \) and every \( t \in Z \), a function \( \phi_i(t) \) on \( Z \) such that

1. \( \| \rho \|_{L^2(\mu)} \leq \delta \);
2. \( \| \phi_i(t) \|_{\infty} \leq 1 \) and \( \| \phi_i(t) \|_{A(d)} \leq C \) for every \( i \) and every \( t \);
3. \( (25) \quad |\phi(x + t) - \sum_{i=1}^{m} 1_{X_i}(x)\phi_i(t)(x)| \leq \rho(x) \) for all \( x, t \in Z \).

Combining this theorem with an approximation result, this gives insight into properties of the dual norm.

**Remark 5.3.** In fact we show a bit more: each function \( \phi_i(t) \) is the sum of a bounded number of functions that are cubic convolution products of functions with \( L^{2d-1}(\mu) \) norm bounded by 1.

**Remark 5.4.** The function \( \phi \) in the statement of Theorem 5.2 satisfies \(|\phi| \leq 1\) and thus \(0 \leq \rho \leq 2\).

Furthermore, the function \( \phi \) belongs to \( A(d+1) \), with \( \|\phi\|_{A(d+1)} \leq 1 \). But Theorem 5.2 can not be extended to all functions belonging to \( A(d+1) \), even for \( d = 1 \).

**Remark 5.5.** Theorem 5.2 holds for \( d = 1 \), keeping in mind that \( A(1) \) consists of constant functions and that \( \|\cdot\|_{A(1)} \) is the absolute value.

In this case, the results can be proven directly and we sketch this approach. In Section 4.3, we showed that the Fourier coefficients of the function \( \phi \) satisfy

\[
\sum_{\xi \in \hat{Z}} |\hat{\phi}(\xi)|^{2/3} \leq 1.
\]

Let \( \psi \) be the trigonometric polynomial obtained by removing the Fourier coefficients in \( \phi \) that are less than \( \delta^3 \). The error term satisfies \( \|\phi - \psi\|_{\infty} \leq \delta \) and so the function \( \rho \) in the theorem can be taken to be the constant \( \delta \). There are at most \( 1/\delta^2 \) characters so that \( \hat{\psi}(\xi) \neq 0 \). Taking a finite partition such that each of these characters is essentially constant on each set in the partition, we have that for every \( t \) the function \( \phi_t \) is essentially constant on each piece of the partition.

Before turning to the proof, we need some definitions, notation, and further results. Throughout the remainder of this section, we assume that an integer \( d \geq 1 \) is fixed, and the dependence of all constants on \( d \) is implicit in all statements. For notational convenience, we study functions belonging to \( A(d + 1) \) instead of \( A(d) \).
5.2. Regularity Lemma.

**Definition 5.6.** Fix an integer $D \geq 2$. Let $(X, \mu)$ be a probability space of one of the two types considered in Definition 5.1.

Let $\nu$ be a measure on $Z^D$ such that each of its projections on $Z$ is equal to $\mu$.

Let $\mathcal{P}$ be a partition of $Z$. An atom of the product partition $\mathcal{P} \times \ldots \times \mathcal{P}$ ($D$ times) of $Z^D$ is called a rectangle of $\mathcal{P}$.

A $\mathcal{P}$-function on $Z^D$ is a function $f$ that is constant on each rectangle of $\mathcal{P}$.

For a function $F$ on $Z^D$, we define $F_\mathcal{P}$ to be the $\mathcal{P}$-function obtained by averaging over each rectangle with respect to the measure $\nu$: for every $x \in Z^D$, if $R$ is the rectangle containing $x$, then

$$F_\mathcal{P}(x) = \begin{cases} \frac{1}{\nu(R)} \int F \, d\nu & \text{if } \nu(R) \neq 0; \\ 0 & \text{if } \nu(R) = 0. \end{cases}$$

An $m$-step function is a $\mathcal{P}$-function for some partition $\mathcal{P}$ into at most $m$ sets.

As with $d$, we assume that the integer $D$ is fixed throughout and omit the explicit dependencies of the statements and constants on $D$.

We make use of the following version of the Regularity Lemma, a modification of the analytic version of Szemerédi’s Regularity Lemma in [10]:

**Theorem 5.7** (Regularity Lemma, revisited). For every $D$ and $\delta > 0$, there exists $M = M(D, \delta)$ such that if $(X, \mu)$ and $\nu$ are as in Definition 5.6, then for every function $F$ on $Z^D$ with $|F| \leq 1$, there is an almost uniform partition $\mathcal{P}$ of $Z$ into $m \leq M$ sets such that for every $m$-step function $U$ on $Z^D$ with $|U| \leq 1$,

$$\left| \int U(F - F_\mathcal{P}) \, d\nu \right| \leq \delta .$$

We defer the proof to Appendix A. In the remainder of this section, we carry out the proof of Theorem 5.2.

5.3. An approximation result for decomposable functions. We return to our usual definitions and notation. We fix $d \geq 1$ and apply the Regularity Lemma to the probability space $(Z, \mu)$, $D = 2^d$ and the probability measure $\mu_d$ on $Z^{2^d}$.

In this section, we show an approximation result that allows to go from weak to strong approximations:
Proposition 5.8. Let $F$ be a function on $Z_d$ belonging to $D(d)$ with $\|F\|_{D(d)} \leq 1$ and $\|F\|_{\infty} \leq 1$. Let $\theta > 0$ and $\mathcal{P}$ be the partition of $Z$ associated to $F$ and $\theta$ by the Regularity Lemma (Theorem 5.7). Then there exist constants $C = C(d) > 0$ and $c = c(d) > 0$ such that

$$\|F - F_\mathcal{P}\|_2 \leq (C\theta^c + \theta)^{1/2}.$$ 

We first prove a result that allows us to pass from sets to functions:

Lemma 5.9. Assume that $F$ is a function on $Z_d$ with $\|F\|_{\infty} \leq 1$. Let $\theta > 0$ and let $\mathcal{P}$ be the partition of $Z$ associated to $F$ and $\theta$ by the Regularity Lemma (Theorem 5.7). If $f_{\vec{\epsilon}}, \vec{\epsilon} \in V_d$, are functions on $Z$ satisfying $\|f_{\vec{\epsilon}}\|_{2^d} \leq 1$ for every $\vec{\epsilon}$, then

$$\|F - F_\mathcal{P}\|_{D(d)} \leq C \theta^c.$$ 

Proof. By construction, $\mathcal{P}$ is an almost uniform partition of $Z$ into $m < M(\eta)$ pieces and the function $F = F_\mathcal{P}$ satisfies

$$\|\mathbb{E}_{Z_d} U(F - F_\mathcal{P})\| \leq \eta$$

for every $m$-step function $U$ on $Z_d$ with $|U| \leq 1$. We show (26).

By possibly changing the constant $C$, we can further assume that the functions $f_{\vec{\epsilon}}$ are all non-negative. Let $\eta > 0$ be a parameter, with its value to be determined. For $\vec{\epsilon} \in \{0, 1\}^d$, set

$$f_{\vec{\epsilon}}'(x) = \min(f_{\vec{\epsilon}}(x), \eta) \quad \text{and} \quad f_{\vec{\epsilon}}''(x) = f_{\vec{\epsilon}} - f_{\vec{\epsilon}}'(x).$$

Thus the average of (26) can be written as a sum of $2^d$ averages, which we deal with separately.

a) We first show that

$$\|\mathbb{E}_{x \in Z_d}(F - F_\mathcal{P})(x) \prod_{\vec{\epsilon} \in V_d} f_{\vec{\epsilon}}'(x_{\vec{\epsilon}})\| \leq \eta^{2^d}.\theta.$$ 

For $u \in \mathbb{R}_+$, write

$$A(\vec{\epsilon}, u) = \{x \in Z : f_{\vec{\epsilon}}(x) \leq u\}.$$ 

For each $\vec{\epsilon} \in \{0, 1\}^d$, we have that

$$f_{\vec{\epsilon}}'(x) = \int_0^\eta 1_{A(\vec{\epsilon}, u)}(x) \, du.$$
and so the average of the left hand side of (28) is the integral over
\( u = (u_\varepsilon: \varepsilon \in V_d) \in [0, \eta]^{2d} \) of
\[
E_{x \in Z_d} (F - F_P)(x) \prod_{\varepsilon \in V_d} 1_{A(\varepsilon, u_\varepsilon)}(x_\varepsilon).
\]

By (27), for each \( u \in [0, \eta]^{2d} \), the absolute value of this average is bounded by \( \theta \). Integrating, we have the bound (28).

b) Assume now that for each \( \varepsilon \in \{0, 1\}^d \), the function \( g_\varepsilon \) is equal either to \( f'_\varepsilon \) or to \( f''_\varepsilon \), and that there exists \( \alpha \in \{0, 1\}^d \) with \( g_\alpha = f''_\varepsilon \). We show that
\[
\left| E_{x \in Z_d} (F - F_P)(x) \prod_{\varepsilon \in V_d} g_\varepsilon(x_\varepsilon) \right| \leq 2\eta^{-2d+1}.
\]

Since \( |F - F_P| \leq 2 \) and the functions \( g_\varepsilon \) are nonnegative, it suffices to show that
\[
E_{x \in Z_d} \prod_{\varepsilon \in \{0, 1\}^d} g_\varepsilon(x_\varepsilon) \leq \eta^{-2d+1}.
\]

By Corollary 2.5, the left hand side is bounded by
\[
\prod_{\varepsilon \in V_d} \|g_\varepsilon\|_{L^{2d-1}(\mu)} \cdot \|g_\alpha\|_{L^1(\mu)} \leq \|g_\alpha\|_{L^1(\mu)} = \int 1_{f_\alpha > \eta}(x) f_\alpha(x) \leq \|f_\alpha\|_{2d}\mu\{x \in Z: f_\alpha(x) \geq \eta\}^{(2d-1)/2d} \leq \eta^{-2d+1}
\]
and we have the statement.

c) The left hand side of (26) is thus bounded by
\[
\eta^{2d} \theta + 2(2^d - 1)\eta^{-2d+1}.
\]
Taking \( \eta = \theta^{-1/(2d+1-1)} \), we have the bound (26). \( \square \)

We now use this to prove the proposition:

**Proof of Proposition 5.8.** Since \( F \) belongs to \( D(d) \) with \( \|F\|_{D(d)} \leq 1 \), it follows from the definition of this norm and from Lemma 5.9 that \( |E_{x \in Z_d} (F - F_P)(x) F'(x)| \leq C\theta^c \).

On the other hand, \( F_P \) is an \( m \)-step function and by the property of the partition \( P \) given by Theorem 5.7, we have that \( |E_{x \in Z_d} (F - F_P)(x) F_P(x)| \leq \theta \). Finally, \( E_{x \in Z_d} ((F - F_P)(x)^2) \leq C\theta^c + \theta. \) \( \square \)

5.4. **Proof of Theorem 5.2.** We use the notation and hypotheses from the statement of Theorem 5.2.
a) A decomposition. Define $P : L^1(\mu_d) \to L^1(\mu)$ to be the operator of conditional expectation. The most convenient definition of this operator is by duality: for $h \in L^\infty(\mu)$ and $H \in L^1(\mu_d)$,

$$\int_Z h(x) \, P H(x) \, d\mu(x) = \int_{Z_d} h(x_0) H(x) \, d\mu_d(x).$$

Recall that $\|P H\|_{L^1(\mu_d)} \leq \|H\|_{L^1(\mu_d)}$.

By definition, when $H(x) = \prod_{\vec{\epsilon} \in \hat{V}} d f_{\vec{\epsilon}}(x_{\vec{\epsilon}})$, where the functions $f_{\vec{\epsilon}}$ belong to $L^{2d-1}(\mu)$, then

$$(29) \quad P H(x) = \mathbb{E}_{\vec{t} \in Z_d} \prod_{\vec{\epsilon} \in \hat{V}_d} f_{\vec{\epsilon}}(x + \vec{\epsilon} \cdot \vec{t}).$$

For $x \in Z_d$, define

$$G(x) = \bigotimes_{\vec{\epsilon} \in \hat{V}_d} f_{\vec{\epsilon}}(x_{\vec{\epsilon}}) = \prod_{\vec{\epsilon} \in \hat{V}_d} f_{\vec{\epsilon}}(x_{\vec{\epsilon}})$$

$$F(x) = \left( \prod_{\vec{\epsilon} \in \hat{V}_d} f_{\vec{\epsilon}} \right)(x) = \mathbb{E}_{u \in Z} \prod_{\vec{\epsilon} \in \hat{V}_d} f_{\vec{\epsilon}}(x_{\vec{\epsilon}} + u).$$

For $x \in Z$, we have

$$\phi(x) = \mathbb{E}_{\vec{s} \in Z_d} \prod_{\vec{\epsilon} \in \hat{V}_d} \left( f_{\vec{0}}(x + \vec{\epsilon} \cdot \vec{s}) \mathbb{E}_{u \in Z} \prod_{\vec{\epsilon} \in \hat{V}_d} f_{\vec{\epsilon}}(x_{\vec{\epsilon}} + \vec{\epsilon} \cdot \vec{s} + u) \right)$$

$$= P(G \cdot F).$$

Recall that for $t \in Z$, $\phi_t$ is the function on $Z$ defined by $\phi_t(x) = \phi(x + t)$.

For $t \in Z$ and $x \in Z_d$, define

$$G_{t\Delta}(x) = G(x + t\Delta) = \prod_{\vec{\epsilon} \in \hat{V}_d} f_{\vec{0}}(x_{\vec{\epsilon}} + t).$$

Since the function $F$ is invariant under diagonal translations, for $x, t \in Z$ we have that

$$\phi_t(x) = P(G_{t\Delta} \cdot F)(x).$$

By Proposition 4.11, the function $F$ belongs to $D(d)$ and $\|F\|_{D(d)} \leq 1$. Thus $\|F\|_{\infty} \leq 1$.

Let $\delta > 0$. Let $c$ and $C$ be as in Proposition 5.8 and let $\theta > 0$ be such that $(C\theta^c + \theta)^{1/2} < \delta$. Let $\mathcal{P}$ and $F_{\mathcal{P}}$ be associated to $F$ and $\theta$ as in the Regularity Lemma. Let $\mathcal{P} = (A_1, \ldots, A_m)$. 
For \( x, t \in \mathbb{Z} \), we have that
\[
\phi_t(x) = P(G_t \cdot (F - F_P)) + P(G_t \cdot F_P)
\]
and we study the two parts of this sum separately.

b) Bounding the rest. Define
\[
\rho(x) = \left( P(F - F_P)^2 \right)^{1/2}.
\]
We have that
\[
\|\rho\|_2 = \|P(F - F_P)^2\|_{L^2(\mu_d)}^{1/2} \leq \|(F - F_P)^2\|_{L^2(\mu_d)}^{1/2} = \|F - F_P\|_{L^2(\mu_d)} \leq \delta,
\]
where the last inequality follows from Proposition 5.8. Moreover,
\[
|P(G_t \cdot (F - F_P))| \leq \left( P(G_t^2) \right)^{1/2} \cdot \left( P(F - F_P)^2 \right)^{1/2} \leq \rho(x)
\]
by (29) and Lemma 2.3.

c) The main term. We write elements of \( \{1, \ldots, m\}^{2d} \) as
\[
j = (j_{\vec{e}}: \vec{e} \in V_d).
\]
For \( j = (j_{\vec{e}}: \vec{e} \in V_d) \in \{1, \ldots, m\}^{2d} \), write
\[
R_j = \prod_{\vec{e} \in V_d} A_{j_{\vec{e}}}.
\]
The function \( F_P \) is equal to a constant on each rectangle \( R_j \). Let \( c_j \) be this constant. We have that \( |c_j| \leq 1 \).

For \( 1 \leq i \leq m \) and \( t, x \in \mathbb{Z} \), define
\[
\phi_i^{(t)}(x) := \mathbb{E}_{\vec{e} \in Z^d} \sum_{j \in \{1, \ldots, m\}^{2d}} c_j \prod_{\vec{e} \in V_d} 1_{A_{j_{\vec{e}}}}(x + \vec{e} \cdot \vec{s}).\phi_{\vec{e}0}(x + \vec{e} \cdot \vec{s}).
\]
Since distinct rectangles are disjoint, it follows that
\[
\left| \sum_{j \in \{1, \ldots, m\}^{2d}} c_j \prod_{\vec{e} \in V_d} 1_{A_{j_{\vec{e}}}}(x + \vec{e} \cdot \vec{s}).\phi_{\vec{e}0}(x + \vec{e} \cdot \vec{s}) \right| \leq \prod_{\vec{e} \in V_d} |\phi_{\vec{e}0}(x + \vec{e} \cdot \vec{s})|.
\]
Thus
\[
|\phi_i^{(t)}(x)| \leq 1.
\]
On the other hand, the function \( \phi_i^{(t)} \) is the sum of \( m^{2d-1} \) functions belonging to \( A(d) \) with norm \( \leq 1 \) and thus
\[
\|\phi_i^{(t)}\|_{A(d)} \leq C = M^{2d-1}.
\]
We claim that

\[ P(G_t \cdot \mathcal{F}_p) = \sum_{i=1}^{m} 1_{A_i}(x) \phi_i^{(t)}(x). \]

Via the definitions, we have that

\[ (G_t \cdot \mathcal{F}_p)(x) = \sum_{j \in \{1, \ldots, m\}^{zd}} c_j \prod_{\vec{c} \in V_d} f_{\vec{c}0}(x_{\vec{c}}) \prod_{\vec{e} \in V_d} 1_{A_{j\vec{c}}}(x_{\vec{e}}). \]

Grouping together all terms of the sum with \( j_0 = i \) and using (29), we obtain (30). This completes the proof of Theorem 5.2. \( \square \)

6. Further directions

We have carried this study of Gowers norms and associated dual norms in the setting of compact abelian groups. This leads to a natural question: what is the analog of the Inverse Theorem for groups other than \( \mathbb{Z}_N \)? What would be the generalization for other finite groups or for infinite groups such as the torus, or perhaps even for totally disconnected (compact abelian) groups?

In Section 3.5 we give examples of functions with small dual norm, obtained by embedding in a nilmanifold. One can ask if this process is general: does one obtain all functions with small dual norm, up to a small error in \( L^1 \) in this way? In particular, for \( \mathbb{Z}_N \) this would mean that in the Inverse Theorem we can replace the family \( \mathcal{F}(d, \delta) \) by a family of nilsequences with “bounded complexity” that are periodic, with period \( N \), meaning that they all come from embeddings of \( \mathbb{Z}_N \) in a nilmanifold.

By the computations in Section 4.3 we see a difference between \( A(2) \) and the dual functions: the cubic convolution product \( f \) of functions belonging to \( L^2(\mu) \) satisfies \( \sum |\hat{f}|^{2/3} < \infty \), while \( A(2) \) is the family of functions \( f \) such that \( \sum |\hat{f}(\xi)| < +\infty \). It is natural to ask what analogous distinctions are for \( d > 2 \).

Appendix A. Proof of the regularity lemma

We make use of the following version of the Regularity Lemma in a Hilbert space introduced in [10]:

**Lemma A.1** (Lovasz and Szegedy [10]). Let \( K_1, K_2, \ldots \) be arbitrary nonempty subsets of a Hilbert space \( \mathcal{H} \). Then for every \( \varepsilon > 0 \) and \( f \in \mathcal{H} \), there exists \( k \leq \lceil 1/\varepsilon^2 \rceil \) and \( f_i \in K_i, i = 1, \ldots, k \) and \( \gamma_1, \ldots, \gamma_k \in \mathbb{R} \) such that for every \( g \in K_{k+1}, \)

\[ |\langle g, f - (\gamma_1 f_1 + \ldots + \gamma_k f_k) \rangle| \leq \varepsilon \cdot \|g\| \cdot \|f\|. \]
A POINT OF VIEW ON GOWERS UNIFORMITY NORMS 33

For the proof of Theorem 5.7, we follow the proof of the strong form of the Regularity Lemma in [10].

Proof of Theorem 5.7. We only consider the infinite case only, as the proof in the finite case is similar.

Choose a sequence of integers $(1) < s(2) < \ldots$ such that

$$(s(1)s(2)\ldots s(i))^2 < s(i+1)$$

for each $i \in \mathbb{N}$ and such that $D/\varepsilon < s(1)$.

Let $Q$ be a partition of $\mathbb{Z}$ into at most $s(i)$ sets and let $K_i$ consist of $Q$-functions.

By Lemma A.1 there exists $k \leq \lceil 1/\varepsilon^2 \rceil$ and there exists an $s(1)\ldots s(k)$-step function $F^*$ such that

$$\left| \int U(F - F^*) \, d\nu \right| \leq \varepsilon$$

for any $s(k+1)$-step function $U$. Choose $m$ with $D/\varepsilon < m < s(k+1)$ and refine the partition defining $F^*$ into a partition $S = \{S_1, \ldots, S_m\}$ into $m$ sets. Then $F^*$ is a $S$-function and the bound (31) remains valid for every $m$-step function $U$.

Partition each set $S_i$ into subsets of measure $1/m^2$ and a remainder set of measure smaller than $1/m^2$. Take the union of all these remainder sets and partition this union into sets of measure $1/m^2$. Thus we obtain a partition $P = \{A_1, \ldots, A_{m^2}\}$ of $\mathbb{Z}$ into $m^2$ sets of equal measure.

At least $m^2 - m$ of these $m^2$ sets are good, meaning that the set is included in some set of the partition $S$. Let $G$ denote the union of these good sets and call it the good part of $\mathbb{Z}$. We have that

$$\nu(Z^D \setminus G^D) \leq D/m \leq \varepsilon.$$

We claim that if $U$ is an $m$-step function with $|U| \leq 1$, then

$$\left| \int U(F - F_P) \, d\nu \right| \leq 4\varepsilon.$$

To show this, set $U' = 1_G \cdot U$. Then

$$\left| \int (U - U')(F - F_P) \, d\nu \right| \leq 2 \int |U - U'| \, d\nu \leq 2\varepsilon.$$

Moreover, $U'$ is an $m$-step function with $|U'| \leq 1$ and by hypothesis,

$$\left| \int U'(F - F^*) \, d\nu \right| \leq \varepsilon$$

and we are reduced to showing that

$$\left| \int U'(F^* - F_P) \, d\nu \right| \leq \varepsilon.$$
Instead, assume that
\[ \int U''(F^* - F_P) \, d\nu > \varepsilon \]
and we derive a contradiction (the opposite bound is proved in the same way).

Define a new function \( U'' \) on \( \mathbb{Z}^D \). Set \( U'' = 0 = U' \) outside \( G^D \). Let \( R \) be a product of good sets. The functions \( F^* \) and \( F_P \) are constant on \( R \) and thus the function \( F^* - F_P \) is constant on \( R \). Define \( U'' \) on \( R \) to be equal to 1 if this constant is positive and to be \(-1\) if this constant is negative. Then \( U''(F^* - F_P) \geq U'(F - F_P) \) on \( R \) and so
\[ \int U''(F^* - F_P) \, d\nu \geq \int U'(F^* - F_P) \, d\nu > \varepsilon . \]
On the other hand, \( U'' \) is a \( \mathcal{P} \)-function and so by definition of \( F_P \),
\[ \int U''(F - F_P) \, d\nu = 0 \]
and
\[ \int U''(F^* - F) \, d\nu > \varepsilon . \]
But \( U'' \) is an \( m \)-step function with \( |U''| \leq 1 \) and this integral is \(< \varepsilon \)
by (31), leading to a contradiction.

\[ \square \]
