Benign airway lesion
Argon plasma coagulation

A B S T R A C T

Fibroepithelial polyps are benign lesions, frequently found in the skin and genitourinary tract. Airway involvement is rare, and few case reports have been published. Our patient was a 79 y.o. male smoker, who was referred to us with a 3-month history of dry cough. At physical examination, the patient looked well, but a chest CT showed a 6-mm polyp lesion in his trachea. A flexible bronchoscopy confirmed this lesion, and forceps biopsies were performed. Argon plasma coagulation was used to completely resect and treat the lesion. Pathological analysis revealed a fibroepithelial polyp (FP). The aim of this manuscript is to report a case of FP with bronchoscopic management and to review the current literature about this condition.

1. Introduction

Benign airway lesions are uncommon, comprising less than 2% of all airway lesions. Estimate prevalence according United State of America data is 2.6 per 100,000 habitants. These lesions compromise tracheobronchial tree and are related with an increased risk of complication, including life threatening condition. Etiology includes hamartomas (chondroid, non chondroid), inflammatory polyps, papillomas (simple, glandular, squamous), leiomiomas, schwannomas, hemangiomas, tumorlets, neurofibroma. Consequences are related to occlusion of the airway lumen due to intraluminal proliferation of the tumor as well as potential malignant transformation [1].

Fibroepithelial polyps (FP) consist of a benign proliferation commonly found in the skin and genitourinary tract [2]. Respiratory fibroepithelial polyposis is an infrequent disease, poorly described, and without a clear pathogenesis. However, due to the improvement of the available quality of imaging in chest radiology and bronchoscopy, several cases of this disease have been reported in upper and lower airways. Prompt diagnosis and interpretation of radiological and bronchoscopic findings are necessary to evaluate the clinical and pathological behavior of respiratory fibroepithelial polyposis [3].

We report a case of FP, including a literature review using the PubMed (MEDLINE), Lilacs, and Google scholar databases.

2. Case report

A 79-year-old male with a 20 year history of smoking was referred to us with a dry cough of 3 month duration. He had no prior history of respiratory allergies, gastroesophageal reflux symptoms or chronic sinus symptoms. He had not experienced fevers, dyspnea or symptoms of bronchial obstruction. The patient's only pre-existing condition was well-controlled blood hypertension.

At physical examination, he was afebrile and morbidly obese (BMI 31 kg/m²). His blood pressure was 135/88, pulse was 82 beats/minute, and respiratory rate was within normal range. Oxygen saturation was 95% on room air and his lungs were clear to auscultation. The rest of the physical examination was unremarkable.

Laboratory testing showed a normal white blood count, without...
hemoptysis, and one case presented with airway obstruction. In our review, 6/30 (20%) cases were associated with symptoms such as airway obstruction and hemoptysis are frequent. In our review, 6/30 (20%) cases were associated with symptoms such as airway obstruction and hemoptysis are frequent.

Fig. 1. Chest CT showed a 6mm polypoid lesion at the right lateral aspect of the proximal trachea.

Flexible bronchoscopy revealed a polypoid lesion with a pink mucosa and firm consistency in the right lateral wall of the proximal trachea (Fig. 1). We biopsied the lesion with forceps, then used argon plasma coagulation to entirely resect the lesion and treat the base. The pathology report described a polyp with a long stalk and marked papillary or finger-like projections. The nodules consisted of fibrovascular stroma with scattered lymphocytes, plasma cells, and erythrocytes, and lined by normal epithelium with ciliated pseudostratified columnar epithelia. (Fig. 3a–d) Complementary analyses using protein C, which is reactive for human papillomavirus (HPV) 6 and 11, were negative.

Follow up: One month after the procedure, the patient’s cough had diminished but had not disappeared completely. We believe his cough was also caused by respiratory allergies.

3. Discussion

Fibroepithelial polyposis is a rare and benign disease described initially by Rowlands and cols [4] in 1960. In our literature review we found 30 cases of airway fibroepithelial polyps, including our case [2,3,5–8]. The average age at diagnosis was 61 years (Standard deviation ±14.72 years). This disease was most frequently found in men (25/30 cases, or 83%). Symptoms are mild or seen in association with pneumonia. Several cases were diagnosed only as an incidental radiological finding, discovered in association with pneumonia (10 cases), or in 8 asymptomatic cases. However, when the size of the FP lesion is bigger, symptoms such as airway obstruction and hemoptysis are frequent. In our review, 6/30 (20%) cases were associated with hemoptysis, and one case presented with airway obstruction.

Differential diagnoses for FP lesions include neoplasia (bronchogenic carcinoma, metastatic lesions to the airway, plasmacytomas); rheumatologic disorders (vasculitis, amyloidosis, rheumatoid arthritis); infections (papilloma virus, mucus plug) and benign airway lesions (chondromas, central airway granulomas, leiomymyomas, lipoma, neuroma, hamartomas).

Radiologic findings usually show a well-defined polyp lesion, and lobulated margins of the polyp are recognizable with chest CT scan [9]. Size and location of FP varies widely. We found an average diameter size of 15.30 mm (SD 19.12 mm), with 15/30 cases (50%) located in right bronchial tree, 11 (37%) in left bronchial tree, and 4 (13%) in the trachea. A literature review of the clinical, radiological and therapeutic approaches of the published cases is summarized in Table 1.

Bronchoscopic evaluation reveals a pedunculated firm polypoid lesion, with a pink colored mucosa. These are important characteristics for evaluating this endobronchial lesion [5]. Histologic findings of a fibroepithelial polyp demonstrate a regular, normal respiratory epithelium with a core of connective tissue. The stromal component is dense, with a collagenous hypcellular matrix with thin-walled vessels, and lacking epithelial overgrowth. Herpes papilloma virus analysis must be negative [9]. The most common treatment includes endoscopic procedures such as endobronchial excision with biopsy forceps. However, an endoscopic thermoablative technique (argon plasma coagulation, electrocautery or laser) can be used in addition to completely resect and treat the polyp. Rigid bronchoscopy is recommended for endoluminal lesions with critical airway obstruction. Its working channel and suction power is bigger than flexible bronchoscopy. Tumor resection is also performed using the tip of the rigid scope. Our patient had a 6mm tracheal lesion seen on CT scan, so flexible bronchoscopy resection is safe for small lesions with no significant airway obstruction. For the largest noted lesion (more than 10 mm), surgical resection was utilized [6].

Prognosis is generally good in most cases. No data about mortality associated with fibroepithelial polyps has been published, and no treatment-related mortality has been reported either. The endoscopic approach is a safe and useful method to remove these lesions.

Finally, we have not found any reports on recurrence or malignant transformation of FP. CT images and/or bronchoscopy surveillance are used to follow up others benign tracheobronchial tumors to diagnose recurrence or malignancy [1].

4. Conclusion

Airway fibroepithelial polyps are uncommon benign lesions that...
are usually diagnosed as incidental radiological findings, or in association with pneumonia. A bronchoscopic approach with the use of excisional biopsy and thermoablative technique is a safe and effective treatment.

Contribution

GL SF, AM: Providing the cases, and writing the manuscript and submitting the manuscript. Final approval proof.

YP: pathological data and analysis. Critical analysis and final approval proof.

IC, EF and MR: Contribution: Reviewing and editing the manuscript. Final Approval proof.
