ON QUIVER-THEORETIC DESCRIPTION FOR QUASITRIANGULARITY OF HOPF ALGEBRAS

HUA-LIN HUANG AND GONGXIANG LIU

Abstract. This paper is devoted to the study of the quasitriangularity of Hopf algebras via Hopf quiver approaches. We give a combinatorial description of the Hopf quivers whose path coalgebras give rise to coquasitriangular Hopf algebras. With a help of the quiver setting, we study general coquasitriangular pointed Hopf algebras and obtain a complete classification of the finite-dimensional ones over an algebraically closed field of characteristic 0.

Keywords Hopf algebra, quasitriangularity, Hopf quiver

2000 MR Subject Classification 16W30, 16W35, 16G20

1. INTRODUCTION

Quasitriangular Hopf algebras were introduced by Drinfeld, which play a crucial role in his theory of quantum groups [12]. From the viewpoint of representation theory, quasitriangular Hopf algebras are close relatives of groups and Lie algebras, as their representations form braided tensor categories. The construction and classification of such Hopf algebras have attracted much attention since they appeared. However, the general classification problem is still widely open.

As is well-known, quiver methods are very useful in constructing algebras and studying their representations. Very nice quiver settings for elementary and pointed Hopf algebras have been built in various works [10, 15, 11, 30] and shown their advantage in classifying some interesting classes of Hopf algebras as well as their representations, see for instance [9, 14, 23, 7, 20, 19, 16] and other related works. To us, it seems sensible to ask: is it possible to describe Drinfeld’s quasitriangularity of Hopf algebras via combinatorial properties of Hopf quivers introduced by Cibils and Rosso [11]?

Our main aim is to provide such description and, by making use of it, to contribute to the classification and representation theory of quasitriangular Hopf algebras. In this paper we focus on quasitriangular elementary Hopf algebras, or more precisely the dual situation coquasitriangular pointed Hopf algebras. Recall that, for a Hopf algebra, by elementary we mean the underlying algebra is finite-dimensional and its simple modules are 1-dimensional, while by pointed we mean the simple comodules of the underlying coalgebra are 1-dimensional.
In some sense, what we are studying is the simplest class of quasitriangular Hopf algebras. According to their proximity to groups, quasitriangular elementary Hopf algebras should be viewed as the counterpart of finite abelian groups, as they are finite-dimensional and their simple modules are all 1-dimensional. In this point of view, the class of quasitriangular pointed Hopf algebras lies in the other extreme and so more complicated. Their study is left for future work.

We build a quiver framework for our object and use the combinatorial properties to study the quasitriangularity. Since the quiver approach from the coalgebraic side is more convenient and admits a wider scope (including infinite-dimensional case), and the dual of quasitriangular elementary Hopf algebras are coquasitriangular pointed, so we always work mainly on the latter and mention briefly the dual cases for the former. First we determine the Hopf quivers whose path coalgebras give rise to coquasitriangular Hopf algebras, then we give a Gabriel type theorem for general coquasitriangular pointed Hopf algebras, and finally we provide some examples to elucidate the quiver setting.

We also apply the constructed quiver setting to classify finite-dimensional coquasitriangular pointed Hopf algebras over an algebraically closed field of characteristic 0. First we prove that such Hopf algebras are generated by group-like and skew-primitive elements. The proof relies on the result of Andruskiewitsch, Etingof and Gelaki [1] for the cotriangular case as well as an observation motivated by our quiver setting. This partially confirms a conjecture of Andruskiewitsch and Schneider [3] which says that a finite-dimensional pointed Hopf algebras is generated by its group-like and skew-primitive elements. Then we give an explicit description of finite-dimensional coquasitriangular pointed Hopf algebras via generators and defining relations by making use of the quiver setting along with the lifting theorem of quantum linear spaces due to Andruskiewitsch and Schneider [2].

Throughout the paper, we work over a field $k$. Vector spaces, algebras, coalgebras, linear mappings, and unadorned $\otimes$ are over $k$. The readers are referred to [13, 18] for general knowledge of (co)quasitriangular Hopf algebras, and to [5] for that of quivers and their applications to algebras and representation theory.

2. (CO)QUASITRIANGULAR HOPF ALGEBRAS AND HOPF QUIVERS

This section is devoted to some preliminaries.

2.1. A quasitriangular Hopf algebra is a pair $(H, R)$, where $H$ is a Hopf algebra and $R \in H \otimes H$ is an invertible element satisfying

\begin{align}
(\Delta \otimes \text{id})(R) &= R_{13}R_{23}, \\
(\text{id} \otimes \Delta)(R) &= R_{13}R_{12}, \\
\Delta^0(h) &= R\Delta(h)R^{-1}, \forall h \in H,
\end{align}
where \( \Delta^o \) is the opposite coproduct of \( H \). Writing \( R = \sum R_{1} \otimes R_{2} \), the notation used is

\[
R_{ij} = \sum 1 \otimes \cdots \otimes R_{(1)} \otimes 1 \otimes \cdots \otimes R_{(2)} \otimes \cdots \otimes 1,
\]

the element of \( H \otimes H \otimes \cdots \otimes H \) which is \( R \) in the \( i \)th and \( j \)th factors. We call \( R \) a universal \( R \)-matrix, or a quasitriangular structure, of \( H \). A quasitriangular Hopf algebra \((H, R)\) is called triangular, if

\[
RR_{21} = 1 \otimes 1.
\]

Dually, a coquasitriangular Hopf algebra \((H, R)\) is a Hopf algebra \( H \) and a convolution-invertible linear function \( R : H \otimes H \longrightarrow k \) such that

\[
R(ab, c) = R(a, c_1)R(b, c_2),
\]

\[
R(a, bc) = R(a_1, c)R(a_2, b),
\]

\[
b_1a_1R(a_2, b_2) = R(a_1, b_1)a_2b_2
\]

for all \( a, b, c \in H \). Here and below we use the Sweedler sigma notation \( \Delta(a) = a_1 \otimes a_2 \) for the coproduct. The function \( R \) is called a universal \( R \)-form, or a coquasitriangular structure, of \( H \). Let \( \bar{R} \) denote the convolution-inverse of \( R \). Then the last condition (2.7) is equivalent to

\[
ba = R(a_1, b_1)a_2b_2 \bar{R}(a_3, b_3)
\]

for all \( a, b \in H \). A coquasitriangular Hopf algebra \((H, R)\) is called cotriangular, if

\[
R(a_1, b_1)R(b_2, a_2) = \varepsilon(a)\varepsilon(b)
\]

for all \( a, b \in H \).

2.2. A quiver is a quadruple \( Q = (Q_0, Q_1, s, t) \), where \( Q_0 \) is the set of vertices, \( Q_1 \) is the set of arrows, and \( s, t : Q_1 \longrightarrow Q_0 \) are two maps assigning respectively the source and the target for each arrow. A path of length \( l \geq 1 \) in the quiver \( Q \) is a finitely ordered sequence of \( l \) arrows \( a_1 \cdots a_l \) such that \( s(a_{i+1}) = t(a_i) \) for \( 1 \leq i \leq l - 1 \). By convention a vertex is said to be a trivial path of length 0.

The path coalgebra \( kQ \) is the \( k \)-space spanned by the paths of \( Q \) with counit and comultiplication maps defined by \( \varepsilon(g) = 1 \), \( \Delta(g) = g \otimes g \) for each \( g \in Q_0 \), and for each nontrivial path \( p = a_n \cdots a_1 \), \( \varepsilon(p) = 0 \).

\[
\Delta(a_n \cdots a_1) = p \otimes s(a_1) + \sum_{i=1}^{n-1} a_n \cdots a_{i+1} \otimes a_i \cdots a_1 + t(a_n) \otimes p.
\]

The length of paths gives a natural gradation to the path coalgebra. Let \( Q_n \) denote the set of paths of length \( n \) in \( Q \), then \( kQ = \bigoplus_{n \geq 0} kQ_n \) and \( \Delta(kQ_n) \subseteq \bigoplus_{i+j} kQ_i \otimes kQ_j \). Clearly \( kQ \) is pointed with the set of group-like \( G(kQ) = Q_0 \), and has the following coradical filtration

\[
kQ_0 \subseteq kQ_0 \oplus kQ_1 \subseteq kQ_0 \oplus kQ_1 \oplus kQ_2 \subseteq \cdots
\]

Hence \( kQ \) is coradically graded.
2.3. According to cibils and Rosso [11], a quiver $Q$ is said to be a Hopf quiver if the corresponding path coalgebra $kQ$ admits a graded Hopf algebra structure. Hopf quivers can be determined by ramification data of groups. Let $G$ be a group, $C$ the set of conjugacy classes. A ramification datum $R$ of the group $G$ is a formal sum $\sum_{C\in C} R_C C$ of conjugacy classes with coefficients in $\mathbb{N} = \{0, 1, 2, \ldots \}$. The corresponding Hopf quiver $Q = Q(G, R)$ is defined as follows: the set of vertices $Q_0$ is $G$, and for each $x \in G$ and $c \in C$, there are $R_C$ arrows going from $x$ to $cx$. For a given Hopf quiver $Q$, the set of graded Hopf structures on $kQ$ is in one-to-one correspondence with the set of $kQ_0$-Hopf bimodule structures on $kQ_1$.

The graded Hopf structures are obtained from Hopf bimodules via the quantum shuffle product [28]. Suppose that $Q$ is a Hopf quiver with a necessary $kQ_0$-Hopf bimodule structure on $kQ_1$. Let $p \in Q_l$ be a path. An $n$-thin split of it is a sequence $(p_1, \cdots, p_n)$ of vertices and arrows such that the concatenation $p_n \cdots p_1$ is exactly $p$. These $n$-thin splits are in one-to-one correspondence with the $n$-sequences of $(n-l)$ 0’s and $l$ 1’s. Denote the set of such sequences by $D_l^n$. Clearly $|D_l^n| = \binom{n}{l}$. For $d = (d_1, \cdots, d_n) \in D_l^n$, the corresponding $n$-thin split is written as $dp = ((dp)_1, \cdots, (dp)_n)$, in which $(dp)_i$ is a vertex if $d_i = 0$ and an arrow if $d_i = 1$. Let $\alpha = a_m \cdots a_1$ and $\beta = b_n \cdots b_1$ be paths of length $m$ and $n$ respectively. Let $d \in D_m^{m+n}$ and $\bar{d} \in D_n^{n+m}$ the complement sequence which is obtained from $d$ by replacing each 0 by 1 and each 1 by 0. Define an element

$$(\alpha \cdot \beta)_d = [(d\alpha)_m \cdot (\bar{d}\beta)_n] \cdots [(d\alpha)_1 \cdot (\bar{d}\beta)_1]$$

in $Q_{m+n}$, where $[(d\alpha)_i \cdot (\bar{d}\beta)_i]$ is understood as the action of $kQ_0$-Hopf bimodule on $kQ_1$ and these terms in different brackets are put together linearly by concatenation. In terms of these notations, the formula of the product of $\alpha$ and $\beta$ is given as follows:

$$(2.10) \quad \alpha \cdot \beta = \sum_{d \in D_m^{m+n}} (\alpha \cdot \beta)_d .$$

2.4. Let $H$ be a pointed Hopf algebra. Denote its coradical filtration by $\{H_n\}_{n=0}^\infty$. Define

$$\text{gr}(H) = H_0 \oplus H_1/H_0 \oplus H_2/H_1 \oplus \cdots$$

as the corresponding (coradically) graded coalgebra. Then $\text{gr}(H)$ inherits from $H$ a coradically graded Hopf algebra structure (see e.g. [22]). The procedure from $H$ to $\text{gr} H$ is generally called degeneration and the converse is called lifting by Andruskiewitsch and Schneider in [2].

Due to Van Oystaeyen and Zhang [30], if $H$ is a coradically graded pointed Hopf algebra, then there exists a unique Hopf quiver $Q(H)$ such that $H$ can be realized as a large sub Hopf algebra of a graded Hopf structure on the path coalgebra $kQ(H)$. Here by “large” we mean $H$ contains the subspace $kQ(H)_0 \oplus kQ(H)_1$. 
3. COQUASITRIANGULAR HOPF QUIVERS

In this section we determine the Hopf quivers which give rise to coquasitriangular Hopf algebras. In addition, some classification results of the coquasitriangular structures on such quiver Hopf algebras are given.

3.1. Let $Q$ be a quiver. If the path coalgebra $kQ$ admits a graded coquasitriangular Hopf algebra structure, then we called $Q$ a coquasitriangular Hopf quiver. First we give a combinatorial description of such class of Hopf quivers.

In the following, we need to make use of the classification of Hopf bimodules over a group algebra obtained in [10] by Cibils and Rosso. That is, for a group $G$, the category of $kG$-Hopf bimodules is equivalent to the product of the categories of usual module categories $\prod_{C \in \mathcal{C}} kZ_C - \text{mod}$, where $\mathcal{C}$ is the set of conjugacy classes and $Z_C$ is the centralizer of one of the elements in the class $C \in \mathcal{C}$. In particular, if $G$ is abelian, then the category of $kG$-Hopf bimodules is equivalent to $\prod_{g \in G} kG - \text{mod}$.

**Proposition 3.1.** Let $Q$ be a quiver. Then $Q$ is a coquasitriangular Hopf quiver if and only if $Q$ is a Hopf quiver of form $Q(G, R)$ where $G$ is an abelian group and $R$ a ramification datum.

**Proof.** Assume that $Q$ is a coquasitriangular Hopf quiver and that $(kQ, R)$ is a graded coquasitriangular Hopf algebra. Then in the first place $Q$ must be a Hopf quiver, say $Q(G, R)$. Let $R_0$ be the restriction of $R$ to $kQ_0 \otimes kQ_0$. Note that $kQ_0 = kG$ is a group algebra and that $(kG, R_0)$ is a coquasitriangular Hopf algebra. Therefore by (2.7) we have

$$hg = R_0(g, h)ghR_0(g, h) = gh$$

for all $g, h \in G$. This implies that $G$ is an abelian group.

Conversely, assume that $Q$ is the Hopf quiver $Q(G, R)$ of some abelian group $G$ with respect to a ramification datum $R$. Then we can take the $kQ_0$-Hopf bimodule structure on $kQ_1$ which corresponds to the product of a set of trivial $kG$-modules. This gives rise to a commutative graded Hopf structure on $kQ$. Apparently $(kQ, \varepsilon \otimes \varepsilon)$ is a coquasitriangular Hopf algebra. This proves that $Q$ is a coquasitriangular Hopf quiver. \qed

3.2. Let $Q$ be a coquasitriangular Hopf quiver. The proof of the previous proposition provides only a trivial coquasitriangular Hopf structure on the path coalgebra $kQ$. Now we study nontrivial coquasitriangular structures on $kQ$. Assume that $Q = Q(G, R)$. We start with the simplest case. Fix a graded Hopf structure on $kQ$ which is determined by a given $kG$-Hopf bimodule structure on $kQ_1$. Assume that $R$ is a coquasitriangular structure which concentrates at degree 0, namely, $R(x, y) = 0$ for all homogenous elements $x, y$ unless they lie in $kQ_0$. The following facts are straightforward.
Lemma 3.2. Keep the previous assumptions. Then $R$ is a bicharacter of $G$, that is, for all $f, g, h \in G$,
\[
\begin{align*}
(3.1) \quad R(f, gh) &= R(f, g)R(f, h), \quad R(fg, h) = R(f, h)R(g, h), \\
R(f, e) &= 1 = R(e, f)
\end{align*}
\]
where $e$ is the unit of $G$. Moreover, in $kQ$ the following equations hold:
\[
\begin{align*}
(3.2) \quad \alpha g &= \frac{R(g, t(\alpha))}{R(g, s(\alpha))} \alpha \quad \text{for all } g \in G, \ \alpha \in Q_1, \\
(3.3) \quad \beta \alpha &= \frac{R(t(\alpha), t(\beta))}{R(s(\alpha), s(\beta))} \alpha \beta \quad \text{for all } \alpha, \beta \in Q_1.
\end{align*}
\]

Here and below, the product notation “$\cdot$” is omitted whenever it is clear according to the context.

The preceding lemma indicates that the coquasitriangular structure $R$ and the $kG$-Hopf bimodule structure on $kQ_1$ are mutually determined.

3.3. Let $Q = Q(G, R)$ be a coquasitriangular Hopf quiver. Note that $Q$ is connected if and only if the union of the conjugacy classes with non-zero coefficients in the ramification datum $R$ generates $G$. In general, let $Q(\epsilon)$ denote the connected component containing the unit $\epsilon \in G$, then $Q(\epsilon)_0$ is a normal subgroup of $G$ and as a quiver $Q$ is equivalent to $\cup_{x \in G/\epsilon} Q(x)$ where $Q(x)$ is identical to $Q(\epsilon)$ for all $x$. Similarly, coquasitriangular Hopf structures on $kQ$ can also be decomposed as a crossed product (see e.g. [22]) of $kQ(\epsilon)$, which inherits a sub coquasitriangular structure of $kQ$, with the quotient group algebra $kG/Q(\epsilon)_0$. This enables us to work on only connected Hopf quivers.

Now we are ready to state the main result of this section.

Theorem 3.3. Let $Q = Q(G, R)$ be a connected coquasitriangular Hopf quiver. Then the complete list of coquasitriangular graded Hopf algebra structures $(kQ, R)$ with $Q_0$ equal to $G$ and $R$ concentrating at degree 0 is in one-to-one correspondence with the set of skew-symmetric bicharacters of $G$. Here by “skew-symmetric” it is meant $R(g, h)R(h, g) = 1$ for all $g, h \in G$.

Proof. First assume that $(kQ, R)$ is a coquasitriangular Hopf algebra with $Q_0$ equal to $G$ and $R$ concentrating at degree 0. Then by restricting to $G$, we have showed in Lemma 3.2 that $R$ is a bicharacter of $G$ satisfying (3.2)-(3.3). Assume that $R = \sum_{g \in G} R_g$. Since $Q(G, R)$ is connected, we have $< g \in G | R_g \neq 0 >= G$. Suppose that $R_g \neq 0 \neq R_h$, then in $Q$ there are arrows starting from the unit $\epsilon$ of $G$, say $\alpha : \epsilon \rightarrow g$ and $\beta : \epsilon \rightarrow h$. Then by (2.10) and (3.2)-(3.3) we have
\[
\begin{align*}
\beta \alpha &= [\beta g][\alpha] + [h\alpha][\beta] = R(g, h)[g\beta][\alpha] + [h\alpha][\beta] \\
&= R(g, h)\alpha \beta = R(g, h)[ah][\beta] + R(g, h)[g\beta][\alpha] \\
&= R(g, h)R(h, g)[h\alpha][\beta] + R(g, h)[g\beta][\alpha].
\end{align*}
\]
This implies that $\mathcal{R}(g,h)\mathcal{R}(h,g) = 1$. Since both $g$ and $h$ vary a generating set of $G$, therefore we have $\mathcal{R}(a,b)\mathcal{R}(b,a) = 1$ for all $a, b \in G$.

Conversely, assume that $\mathcal{R}$ is a skew-symmetric bicharacter of $G$. For each arrow in $Q$ with source $\epsilon$, say $\alpha : \epsilon \rightarrow g$, let $h \triangleright \alpha := \mathcal{R}(g,h)\alpha$. This defines a one-dimensional left $G$-module on $k\alpha$. Denote by $V$ the vector space spanned by all arrows with source $\epsilon$ and understand a $G$-module structure on it by defining $G$-action on each arrow as above. Now by the aforementioned results of Cibils and Rosso [10, 11], we can extend the left $G$-module $V$ to a $kG$-Hopf bimodule on $kQ_1$ and this gives rise to a unique graded Hopf algebra structure on the path coalgebra $kQ$. We extend $\mathcal{R}$ trivially to be a function on $kQ \otimes kQ$ such that $\mathcal{R}(x,y) = 0$ whenever one of the homogeneous elements $x, y$ lies out of $kQ_0$. Now we claim that $(kQ, \mathcal{R})$ is a coquasitriangular Hopf algebra. The axioms (2.5)-(2.6) are direct from the definition of the action $h \triangleright \alpha$.

We need to show that the following equation holds

$$\beta \alpha = \mathcal{R}(t(a_m), t(b_n))\alpha \beta \mathcal{R}(s(a_1), s(b_1))$$

for all paths $\alpha = a_m \cdots a_1$, $\beta = b_n \cdots b_1$. Here we use the convention: if $m = 0$, then $\alpha \in Q_0$ and $t(\alpha) = s(\alpha)$. For $\alpha, \beta \in Q_0$, the equation is obvious. For $\alpha \in Q_1$ an arrow with source $\epsilon$ and $\beta \in Q_0$, the equation follows from the definition of the action “$h \triangleright \alpha$” which corresponds to conjugation “$h\alpha h^{-1}$” in the $kG$-Hopf bimodule. Now let $\alpha : g \rightarrow h$ be an arbitrary arrow and $f \in G$. Note that $g^{-1}\alpha$ is an arrow from $\epsilon$ to $g^{-1}h$. Denote it by $\tilde{\alpha}$. Then we have by (3.1) and the previous case that

$$f \alpha = gf \tilde{\alpha} = g\mathcal{R}(g^{-1}h,f)\tilde{\alpha}f = \mathcal{R}(h,f)\alpha f \mathcal{R}(g,f).$$

Finally let $\alpha = a_m \cdots a_1$, $\beta = b_n \cdots b_1$ be arbitrary paths. Then we have by the preceding cases and the product formula (2.10) that

$$\beta \alpha = \sum_{d \in D_{m+n}^{m+n}} [(d\beta)_{m+n}(d\alpha)_{m+n}] \cdots [(d\beta)_{1}(d\alpha)_{1}]$$

$$= \sum_{d \in D_{m+n}^{m+n}} \mathcal{R}(t((d\alpha)_{m+n}), t((d\beta)_{m+n}))(\tilde{\alpha})_{m+n}(d\beta)_{m+n} \cdots \mathcal{R}(t((d\alpha)_{1}), t((d\beta)_{1}))(\tilde{\alpha})_{1}(d\beta)_{1}$$

$$= \mathcal{R}(t(a_m), t(b_n)) \mathcal{R}(s(a_1), s(b_1)) \sum_{d \in D_{m+n}^{m+n}} [(d\alpha)_{m+n}(d\beta)_{m+n}] \cdots [(d\alpha)_{1}(d\beta)_{1}]$$

$$= \mathcal{R}(t(a_m), t(b_n)) \mathcal{R}(s(a_1), s(b_1)) \sum_{d \in D_{m+n}^{m+n}} [(d\alpha)_{m+n}(\bar{d}\beta)_{m+n}] \cdots [(d\alpha)_{1}(d\beta)_{1}]$$

$$= \mathcal{R}(t(a_m), t(b_n))\alpha \beta \mathcal{R}(s(a_1), s(b_1)).$$

In the third equality we have used the fact $t((d\beta)_i) = s((d\beta)_{i+1})$ for $i = 1, \cdots , m+n - 1$. Now we are done. \qed
3.4. In the following we show that the situation “$\mathcal{R}$ concentrates at degree 0” can always be realized as restricting a general coquasitriangular structure. Let $(kQ, \mathcal{R})$ be a coquasitriangular Hopf algebra, define $\mathcal{R}_0$ by $\mathcal{R}_0|_{kQ_0 \otimes kQ_0} := \mathcal{R}|_{kQ_0 \otimes kQ_0}$ and $\mathcal{R}_0|_{kQ_i \otimes kQ_j} := 0$ if $i + j > 0$. Clearly, $\mathcal{R}_0$ concentrates at degree 0.

**Proposition 3.4.** Let $(kQ, \mathcal{R})$ be a coquasitriangular Hopf algebra, then $(kQ, \mathcal{R}_0)$ is coquasitriangular too.

**Proof.** We only show equation (2.7) for $\mathcal{R}_0$ since (2.5) and (2.6) are obvious. Let $a, b$ be two paths in $kQ$ of lengths $m, n$ respectively, then by $(kQ, \mathcal{R})$ is coquasitriangular we have

$$b_1 a_1 \mathcal{R}(a_2, b_2) = \mathcal{R}(a_1, b_1) a_2 b_2.$$

Denote the linear combination of all paths of length $m + n$ appearing in the left (resp. right) side of the above equality by $L_{m+n}(a, b)$ (resp. $R_{m+n}(a, b)$). Therefore,

$$L_{m+n}(a, b) = R_{m+n}(a, b).$$

Note that $L_{m+n}(a, b) = b_1 a_1 \mathcal{R}_0(a_2, b_2)$ and $R_{m+n}(a, b) = \mathcal{R}_0(a_1, b_1) a_2 b_2$, we get what we want. □

3.5. Now the following consequences are immediate.

**Corollary 3.5.** Let $Q = Q(G, R)$ be a coquasitriangular Hopf quiver and $(kQ, \mathcal{R})$ a graded coquasitriangular Hopf algebra.

1. If $Q$ is connected, then $(kQ, \mathcal{R}_0)$ is a cotriangular Hopf algebra.
2. Denote by $\mathcal{R}(\epsilon)$ the restriction of $\mathcal{R}$ on the connected component $Q(\epsilon)$ of $Q$ containing the unit element, then the sub coquasitriangular Hopf algebra $(kQ(\epsilon), \mathcal{R}_0(\epsilon))$ is cotriangular.

Here, it is worthy to note that for graded coquasitriangular Hopf algebras $(kQ, \mathcal{R})$ as above the “connectedness” of $Q$ leads to the “cotriangularity” of $kQ$. Accordingly, a general graded coquasitriangular Hopf algebra $(kQ, \mathcal{R})$ is a crossed product of a cotriangular one with a group algebra. Finally, we remark that there may be many coquasitriangular structures of $kQ$ not concentrating at degree 0. A complete classification is not known yet.

4. QUIVER SETTING FOR COQUASITRIANGULAR POINTED HOPF ALGEBRAS

The aim of this section is to provide a quiver setting for general coquasitriangular pointed Hopf algebras. In particular, a Gabriel type theorem is obtained.

4.1. Assume that $(H, \mathcal{R})$ is a coquasitriangular pointed Hopf algebra. Let $\text{gr}(H)$ be its coradically graded version as mentioned in Subsection 2.4 and
let \( \text{gr}(\mathcal{R}) : \text{gr}(H) \otimes \text{gr}(H) \to k \) be the function defined by (for homogeneous elements \( g, h \in \text{gr}(H) \))

\[
\text{gr}(\mathcal{R})(g, h) = \begin{cases} 
\mathcal{R}(g, h), & \text{if } g, h \in H_0; \\
0, & \text{otherwise}.
\end{cases}
\]

Our first observation is that the degeneration \((\text{gr}(H), \text{gr}(\mathcal{R}))\) of \((H, \mathcal{R})\) does not lose the coquasitriangularity.

**Lemma 4.1.** Assume that \((H, \mathcal{R})\) is a coquasitriangular pointed Hopf algebra, then \((\text{gr}(H), \text{gr}(\mathcal{R}))\) is still a coquasitriangular pointed Hopf algebra.

**Proof.** Denote the multiplication notation in \(\text{gr}(H)\) by \(\circ\). At first, we check the equation (2.5). Take any three homogeneous elements \(a, b, c \in \text{gr}(H)\). If \(a \not\in H_0\) or \(b \not\in H_0\), then

\[
\text{gr}(\mathcal{R})(a \circ b, c) = 0 = \text{gr}(\mathcal{R})(a, c_1) \text{gr}(\mathcal{R})(a, c_2)
\]

by the definition of \(\text{gr}(\mathcal{R})\). If \(a, b \in H_0\) and \(c \not\in H_0\), then clearly either \(c_1 \not\in H_0\) or \(c_2 \not\in H_0\). Also, by the definition of \(\text{gr}(\mathcal{R})\), equation (2.5) is right since both sides are zero. We only need to prove the case \(a, b, c \in H_0\), but this is clear since \(H_0\) is a sub Hopf algebra of \(H\) and hence coquasitriangular. The equation (2.6) can be proved similarly.

Next let us show the equation (2.7). By the Gabriel type theorem for graded pointed Hopf algebras [30] (Theorem 4.5) and pointed coalgebras [8] (Theorem 2.1), there exists a unique Hopf quiver \(Q\) such that \(\text{gr}(H)\) is a sub Hopf algebra of \(kQ\) and \(H\) is sub coalgebra of \(kQ\). By this, we can consider the elements of \(\text{gr}(H)\) and \(H\) as linear combinations of paths. Take \(a, b \in H\) and for simplicity we may assume that \(a, b\) are paths of length \(m, n\) respectively. Since \(H\) is coquasitriangular, one has

\[
b_1a_1\mathcal{R}(a_2, b_2) = \mathcal{R}(a_1, b_1)a_2b_2.
\]

Similar to the proof of Proposition 3.4, we denote the linear combination of all paths of length \(m + n\) appearing in the left (resp. right) side of above equality by \(L_{m+n}(a, b)\) (resp. \(R_{m+n}(a, b)\)). So,

\[
L_{m+n}(a, b) = R_{m+n}(a, b).
\]

Meanwhile, it is not hard to see that we always have

\[
L_{m+n}(a, b) = b_1 \circ a_1 \text{gr}(\mathcal{R})(a_2, b_2), \quad R_{m+n}(a, b) = \text{gr}(\mathcal{R})(a_1, b_1)a_2 \circ b_2.
\]

Now the proof is finished. \(\Box\)

4.2. Our next observation is that, the Gabriel type theorem for pointed Hopf algebras [30] can be restricted to the coquasitriangular situation.

**Theorem 4.2.** Suppose that \((H, \mathcal{R})\) is a coquasitriangular pointed Hopf algebra. Then there exists a unique coquasitriangular Hopf quiver \(Q\) such that \((\text{gr}(H), \text{gr}(\mathcal{R}))\) is isomorphic to a large sub coquasitriangular Hopf structure of \((kQ, \mathcal{R})\).
Proof. Let $G$ denote the set of group-like elements of $H$. Then the coradical $H_0$ of $H$ is the group algebra $kG$. By restricting the function $R$, we have a sub coquasitriangular Hopf algebra $(kG, R)$. This implies that $G$ is an abelian group and $R$ is a bicharacter of it. By the Gabriel type theorem for general pointed Hopf algebras, there exists a unique Hopf quiver $Q = Q(G, R)$ such that $\text{gr}(H)$ is isomorphic to a large sub Hopf algebra of some graded Hopf structure on $kQ$ determined by the $kG$-Hopf bimodule $H_1/H_0$. Note that $(\text{gr}(H), \text{gr}(R))$ is a graded coquasitriangular Hopf algebra with $\text{gr}(R)$ concentrating at degree zero. By the same argument as in the proof of Theorem 3.3, we can show that the $kG$-Hopf bimodule $H_1/H_0$ is completely determined by the bicharacter $\text{gr}(R)$ and so the associated graded Hopf structure on $kQ$ is coquasitriangular. Let $\mathfrak{R}$ be the trivial extension of $\text{gr}(R)$ to the whole $kQ \otimes kQ$, then $(kQ, \mathfrak{R})$ is coquasitriangular and apparently $(\text{gr}(H), \text{gr}(R))$ is isomorphic to a large sub structure of $(kQ, \mathfrak{R})$. This completes the proof. □

4.3. According to a generalization of the Cartier-Gabriel decomposition theorem due to Montgomery [23] (Theorem 3.2), the study of general coquasitriangular pointed Hopf algebras can be reduced to the connected case, namely their quivers (in the sense of Theorem 4.2) are connected. This can also be seen intuitively by the fact that general Hopf quivers consisting of copies of identical connected components.

For a coquasitriangular pointed Hopf algebra $(H, R)$, let $(\text{gr}(H), \text{gr}(R)) \hookrightarrow (kQ, \mathfrak{R})$ be an embedding as in Theorem 4.2. By $\text{gr}(H)(\epsilon)$ we denote the image in the connected component $kQ(\epsilon)$. This is the principal block of $\text{gr}(H)$ which is a sub coquasitriangular Hopf algebra with structure $\text{gr}(R)(\epsilon)$ obtained by the obvious restriction. The other blocks can be obtained by multiplying group-like elements. Then $\text{gr}(H)$ can be recovered as a crossed product of $\text{gr}(H)(\epsilon)$ by a group algebra. The coquasitriangular structure can also be recovered by extending that of $\text{gr}(H)(\epsilon)$ via the formulae (2.5)-(2.6).

Now we have the following directly from Theorem 4.2 and Corollary 3.5.

Corollary 4.3. Let $(H, R)$ be a coquasitriangular pointed Hopf algebra and $(\text{gr}(H), \text{gr}(R))$ its degeneration as before. Then $(\text{gr}(H)(\epsilon), \text{gr}(R)(\epsilon))$ is cotriangular and $(\text{gr}(H), \text{gr}(R))$ is a crossed product of $(\text{gr}(H)(\epsilon), \text{gr}(R)(\epsilon))$ by a group algebra. In particular, if the quiver of $H$ is connected, then $(\text{gr}(H), \text{gr}(R))$ is cotriangular.

It is interesting to note that, coquasitriangular pointed Hopf algebras can always be obtained as lifting of cotriangular ones and crossed product by group algebras if disconnected.

4.4. We include briefly a dual quiver setting for quasitriangular elementary Hopf algebras. In this case, we should use the path algebras of finite quivers (i.e., the set consisting of vertices and arrows is finite) and their admissible quotients to construct algebras.
Let \( Q \) be a finite quiver. The associated path algebra, denoted by \( kQ^a \), has the same underlying vector space as the path coalgebra and the multiplication is defined by concatenation of paths. In fact, the path algebra \( kQ^a \) is the graded dual of the path coalgebra \( kQ \). The path algebra \( kQ^a \) admits a graded Hopf structure if and only if \( Q \) is a Hopf quiver, see [10, 15].

For a quasitriangular elementary Hopf algebra \( (H, R) \), we can consider the graded version \( (\text{gr}(H), \text{gr}(R)) \) induced by its chain of Jacobson radical. With this, a quiver setting for such class of Hopf algebras is given in the following. We state the dual of Proposition 3.1, Theorems 3.3 and 4.2, Corollary 4.3 without further explanation.

**Theorem 4.4.** Let \( Q \) be a finite quiver.

1. Then the path algebra \( kQ^a \) admits a graded quasitriangular Hopf structure if and only if \( Q \) is the Hopf quiver \( Q(G, S) \) of some abelian group \( G \) with respect to a ramification datum \( S \).
2. Assume that \( Q = Q(G, S) \) is a connected Hopf quiver with \( G \) abelian. Then the set of graded quasitriangular Hopf algebras \( (kQ^a, R) \) with \( kQ^a_0 = (kG)^* \) and \( R \in kQ^a_0 \otimes kQ^a_0 \) is in one-to-one correspondence with the set of skew-symmetric bicharacters of \( G \).

**Theorem 4.5.** Let \( (H, R) \) be a quasitriangular elementary Hopf algebra and \( (\text{gr}(H), \text{gr}(R)) \) its radically graded version. Then there exists a unique Hopf quiver \( Q(H) = Q(G, S) \) with \( G \) abelian such that \( \text{gr}(H) \cong kQ(H)^a/I \) as graded quasitriangular Hopf algebras, where \( I \) is an admissible Hopf ideal.

**Corollary 4.6.** Let \( (H, R) \) be a quasitriangular elementary Hopf algebra and \( (\text{gr}(H), \text{gr}(R)) \) its radically graded version. Then the principal block of \( \text{gr}(H) \) is a quotient Hopf algebra and is triangular. The quasitriangular Hopf algebra \( (\text{gr}(H), \text{gr}(R)) \) can be presented as a crossed product of its principal block by the dual of a group algebra in the sense of Schneider [29].

5. EXAMPLES

In this section, we construct some examples via the quiver setting. For the convenience of the exposition, we assume in this section that the ground field \( k \) is the field of complex numbers.

5.1. Let \( \mathbb{Z}_n = \langle g \mid g^n = 1 \rangle \) denote the finite cyclic group of order \( n \). Consider the (coquasitriangular) Hopf quiver \( Q(\mathbb{Z}_n, g) \). It is a basic cycle of length \( n \). For each integer \( i \) modulo \( n \), let \( a_i \) denote the arrow \( g^i \rightarrow g^{i+1} \). Let \( \mathcal{R} \) be a skew-symmetric bicharacter of \( \mathbb{Z}_n \). Then it is completely determined by the value \( \lambda = \mathcal{R}(g, g) \) which should satisfy the equation

\[
\lambda^2 = 1
\]

by skew-symmetry. In general, we have \( \mathcal{R}(g^i, g^j) = \lambda^{ij} \).

If \( n \) is odd, then \( \lambda \) must be 1. Therefore, there is only one skew-symmetric bicharacter, and hence only one graded coquasitriangular Hopf structure concentrating at degree 0 which is isomorphic to \( k[x] \otimes k\mathbb{Z}_n \) as algebra.
If \( n \) is even, then \( \lambda = \pm 1 \). The case when \( \lambda = 1 \) is known. When \( \lambda = -1 \), then we can associate to the bicharacter a \( k\mathbb{Z}_n \)-Hopf bimodule on \( kQ(\mathbb{Z}_n, g)_1 \) as follows:

\[
 ga_i = a_{i+1}, \quad a_{i}g = -a_{i+1}
\]

for all integer \( i \) modulo \( n \). This gives rise to a cotriangular Hopf algebra on \( kQ(\mathbb{Z}_n, g) \) with path multiplication given by

\[
 p^l_ip^m_j = \begin{cases} 
 0, & \text{if } l, m \text{ are odd;} \\
 (-1)^{im}p^{l+m}_{i+j}, & \text{otherwise.}
\end{cases}
\]

Here the notation \( p^l_i \) means the path of length \( l \) with source \( g^i \). In particular, if we consider the sub Hopf algebras generated by vertices and arrows, we get the generalized Taft algebra \( C_2(n, -1) \) as denoted in [7]. It can be presented by generators \( g \) and \( x \) with relations

\[
 g^n = 1, \quad x^2 = 0, \quad gx = -xg.
\]

Note that if \( n = 2 \) then it is exactly the well-known Sweedler’s 4-dimensional Hopf algebra. Such Hopf algebras appeared in the works of Radford [26, 27] in which their quasitriangular structures were classified.

Now we determine all the coquasitriangular structures on \( C_2(n, -1) \). Clearly it has \( \{g^i x^l | i = 0, 1, \cdots n - 1, \ l = 0, 1 \} \) as a basis. Let \( \mathcal{R} \) be a coquasitriangular structure. Then we already know \( \mathcal{R}(g^i, g^j) = (-1)^{ij} \). By

\[
 0 = \mathcal{R}(g, x^2) = \mathcal{R}(g, x)\mathcal{R}(g, x)
\]

we have \( \mathcal{R}(g, x) = 0 \). Then by (2.5)-(2.6) it follows that \( \mathcal{R}(g^i, g^j x) = 0 \). Similarly, we have \( \mathcal{R}(g^i x, g^j) = 0 \). By using (2.8) we have

\[
 0 = x^2 = \mathcal{R}(x, x)1 - \mathcal{R}(x, x)g^2.
\]

On the other hand, by applying \( \mathcal{R} \mathcal{R} = \varepsilon \otimes \varepsilon \) to \( (x, x) \), we can show that \( \mathcal{R}(x, x) = \mathcal{R}(x, x) \). That means,

\[
 \mathcal{R}(x, x)(1 - g^2) = 0.
\]

This forces \( \mathcal{R}(x, x) = 0 \) if \( n > 2 \). Similarly by (2.5)-(2.6) we have in this case \( \mathcal{R}(g^i x, g^j x) = 0 \). That is, the coquasitriangular structure on \( C_2(n, -1) \) \( (n > 2) \) is unique which concentrates at degree 0. If \( n = 2 \), then we have \( \mathcal{R}(x, x) = \mathcal{R}(x, x) \) and \( \mathcal{R}(x, x) \) can take any value. Assume \( \mathcal{R}(x, x) = \nu \). Then by (2.5)-(2.6) it is direct to deduce that

\[
 \mathcal{R}(gx, x) = -\nu, \quad \mathcal{R}(x, gx) = \nu, \quad \mathcal{R}(gx, gx) = \nu.
\]

Of course this is known from Radford’s calculation [26] by the fact that the Sweedler’s 4-dimensional Hopf algebra is self-dual.

We remark that the dual of \( C_2(n, -1) \) can be presented by \( kQ(\mathbb{Z}_n, g^0)/J^2 \) where \( J \) is the ideal generated by the set of arrows. Therefore the elementary Hopf algebra \( kQ(\mathbb{Z}_n, g^0)/J^2 \) \( (n > 2) \) has a unique quasitriangular structure, while \( kQ(\mathbb{Z}_2, g^0)/J^2 \) has a 1-parameter family of quasitriangular structures.
This approach via path algebras was used previously by Cibils in [9] for the quiver $Q(\mathbb{Z}_n, g)$.

5.2. Now we consider the infinite cyclic group $Z = \langle g \rangle$ and the Hopf quiver $Q(Z, g)$ which is a linear chain. The group $Z$ has two skew-symmetric bicharacters, namely, $\mathcal{R}(g^i, g^j) = (±1)^{ij}$. For the trivial bicharacter, the corresponding coquasitriangular Hopf algebra on $kQ(Z, g)$ is isomorphic to $k[x] \otimes kZ$ as algebra. For the nontrivial bicharacter, the coquasitriangular Hopf algebra on $kQ(Z, g)$ has multiplication formula similar to (5.1). The sub Hopf algebra generated by vertices and arrows can be presented by generators $g$, $g^{-1}$ and $x$ with relations

$$gg^{-1} = 1 = g^{-1}g, \quad x^2 = 0, \quad gx = -xg.$$ 

By arguments in the same manner as Subsection 5.1, one can show that it has a unique coquasitriangular structure concentrating at degree 0.

As a direct consequence of the previous two examples, we can see that quantized enveloping algebras and small quantum groups are not coquasitriangular since their subalgebras $U_q(sl_2)^{≥0}$ and $u_q(sl_2)^{≥0}$ have $Q(\mathbb{Z}_n, g)$ and $Q(\mathbb{Z}_m, g)$ respectively as their quivers (see for instance [21, 17]) but with different algebra structures from the coquasitriangular ones we have just classified.

5.3. Note that basic cycles and the linear chain are minimal connected Hopf quivers and are basic ingredients of the general. The previous examples classify all the the possible coquasitriangular structures on these building blocks of general coquasitriangular Hopf quivers. Next we will consider those examples which are compatible gluing of them.

Firstly we consider the Hopf quiver $Q = Q(\mathbb{Z}_n, mg)$. It is a multi-cycle. To avoid the trivial case, we assume $n = 2l$, $m > 1$ and $\mathcal{R}$ is the nontrivial skew-symmetric bicharacter of $\mathbb{Z}_n$. Let $x_i$ ($i = 1, \cdots, m$) denote the arrows with source 1. We have the following multiplication formulae in $(kQ, \mathcal{R})$:

$$x_i^2 = 0, \quad x_ix_j = -x_jx_i, \quad gx_i = -x_i g.$$ 

The sub Hopf algebra, denote by $E(n, m)$, generated by vertices and arrows can be presented by generators $g$ and $x_i$ ($i = 1, \cdots, m$) with additional relations $g^n = 1$. Therefore the algebra has a PBW type basis

$$\{g^i x_1^{\sigma_1} \cdots x_m^{\sigma_m} | i = 0, 1, \cdots, n-1; \sigma_j = 0, 1\}.$$ 

It is not difficult to determine all the coquasitriangular structures. Let $\mathcal{R}$ be a coquasitriangular structure. As in Subsection 5.1, we have

$$\mathcal{R}(g^i, g^j) = (-1)^{ij}, \quad \mathcal{R}(g^i, g^j x_k) = 0 = \mathcal{R}(g^i x_k, g^j)$$ 

and

$$\mathcal{R}(x_i, x_j)(1 - g^2) = 0.$$ 

If $n > 2$, then we have $\mathcal{R}(x_i, x_j) = 0$, and further $\mathcal{R}(g^n x_i, g^n x_j) = 0$ for all $i$ and $j$. Therefore $E(n, m)$ has only one coquasitriangular structure which
is the trivial extension of the bicharacter. If \( n = 2 \), then the Hopf algebra \( E(2, m) \) is known as Nichols’ Hopf algebra [24] and its set of quasitriangular structures were classified by Panaite and Van Oystaeyen in [25]. By the previous equations we can show that its set of coquasitriangular structures is in one-to-one correspondence with the set of the matrices \((R(x_i, x_j))_{m \times m}\). By the fact that \( E(2, m) \) is self-dual, this coincides with the result of Panaite and Van Oystaeyen.

5.4. Finally we consider the Hopf quiver \( Q = Q(G, g + h) \) where \( G \) is the abelian group \(< g > \times < h >\). Assume that the order of \( g \) and \( h \) are \( m \) and \( n \) respectively. A skew-symmetric bicharacter \( R \) of \( G \) is determined by three values \( R(g, g), R(h, h), R(g, h) \). As before, we have the equation

\[
R(g, g)^2 = 1 = R(h, h)^2.
\]

Let \((m, n)\) denote the greatest common divisor of \( m \) and \( n \). Then the order of \( R(g, h) \) should satisfy

\[
\text{ord } R(g, h)|(m, n).
\]

In order to have more interesting examples, we assume further that \( m \) and \( n \) are even. Take the bicharacter \( R \) such that

\[
R(g, g) = -1 = R(h, h).
\]

Let \( q \) denote \( R(g, h) \). Consider the sub coquasitriangular Hopf algebra, denoted by \( H(m, n, q) \), of \((kQ, R)\) generated by the set of vertices and arrows. Let \( x : 1 \rightarrow g \) and \( y : 1 \rightarrow h \) be the arrows with source 1. Then \( H(m, n, q) \) is generated by \( g, h, x, y \) satisfying the following relations

\[
g^m = 1 = h^n, \quad x^2 = 0 = y^2, \quad gx = -xg, \quad hy = -yh,
\]

\[
hx = qxh, \quad yg = qgy, \quad yx = qxy.
\]

As before, it is not hard to determine the complete list of coquasitriangular structures on \( H(m, n, q) \). we do not repeat the detail.

6. CLASSIFICATION OF FINITE-DIMENSIONAL COQUASITRIANGULAR POINTED HOPF ALGEBRAS OVER AN ALGEBRAICALLY CLOSED FIELD OF CHARACTERISTIC 0

From now on our ground field \( k \) is assumed to be algebraically close of characteristic 0. The aim of this section is to give a complete classification of finite-dimensional coquasitriangular pointed Hopf algebras over \( k \).

6.1. Firstly we consider the generation problem of finite-dimensional coquasitriangular pointed Hopf algebras. In [1] Andruskiewitsch, Etingof and Gelaki proved that finite-dimensional cotriangular pointed Hopf algebras are generated by their group-like and skew-primitive elements. It turns out that, with our observation Corollary 4.3, one can extend their result to more general case in a fairly straightforward manner.
Proposition 6.1. Suppose that $H$ is a finite-dimensional coquasitriangular pointed Hopf algebra over $k$. Then as an algebra $H$ is generated by its group-like and skew-primitive elements.

Proof. To prove that $H$ is generated by its group-like and skew-primitive elements, it suffices to prove this is the case for its graded version $\text{gr} H$. By Corollary 4.3, the Hopf algebra $\text{gr} H$ is coquasitriangular and is a crossed product of a cotriangular one by a group algebra. Note that the cotriangular one is the principal block of $\text{gr} H$, while other blocks are obtained by multiplying group-like elements. Now apply the theorem of Andruskiewitsch, Etingof and Gelaki [1] (Theorem 6.1), we can say that $\text{gr} H$ is generated by its group-likes and the skew-primitives of its principal block. The proposition follows immediately from this. The proof is completed. □

6.2. Next we study a general finite-dimensional coquasitriangular pointed Hopf algebras $(H, R)$ via its quiver setting. We may assume without loss of generality that $H$ is connected. Let $G$ denote its group of group-like elements. The quiver $Q$ of $H$ is assumed to be $Q(G, R)$ with ramification datum $R = \sum_{i=1}^{t} R_i g_i$. Here the $R_i$’s are assumed to be positive integers if $t \geq 1$.

Proposition 6.2. Keep the above assumptions and notations. If $G$ is the unit group $\{1\}$, then $H \cong k$. When $G \neq \{1\}$, we have

1. $t \geq 1$ and the order of $g_i$ is even for all $i$. In particular the order of $G$ is even.
2. $R$ is a skew-symmetric bicharacter of the group $G$ (by restriction) and $R(g_i, g_i) = -1$ for all $i$.
3. $(\text{gr}(H), \text{gr}(R))$ is isomorphic to the sub coquasitriangular Hopf algebra of $(kQ, R)$ generated by vertices and arrows, where $R$ is obtained by trivial extension of the bicharacter $R$ of $G$.

Proof. By Theorem 4.2, we can view $(\text{gr}(H), \text{gr}(R))$ as a large sub coquasitriangular Hopf algebra of $(kQ, R)$. Therefore $\text{gr}(H)$ contains the sub Hopf algebra generated by vertices and arrows of $Q$.

If $G = \{1\}$, and suppose that there was an arrow $x$ in $Q$. Then by the multiplication formula (2.10) it is easy to verify that the sub Hopf algebra generated by $x$ is actually isomorphic to the polynomial algebra in one variable which is of course infinite-dimensional. This is absurd since we assume the dimension of $H$, hence of $\text{gr}(H)$, is finite. Therefore the quiver $Q$ is a single vertex and so $H$ must be $k$.

In the following we assume that $G \neq \{1\}$. Since the quiver $Q$ is assumed to be connected, so there are arrows and therefore the ramification datum $R$ is not 0. It follows that $t \geq 1$. By Corollary 4.3, $(\text{gr}(H), \text{gr}(R))$ is cotriangular, therefore $\text{gr}(R)$ is a skew-symmetric bicharacter of $G$ which is the restriction of $R$. This implies that, by restriction, $R$ is a skew-symmetric character of $G$. By the assumption $R = \sum_{i=1}^{t} R_i g_i$, we know the quiver $Q$ contain the sub
Hopf quivers $Q(<g_i>, g_i)$ which are basic cycles. By Subsection 5.1, the sub coquasitriangular Hopf algebra of $kQ(<g_i>, g_i)$ generated by vertices and arrows is finite-dimensional if and only if $\mathcal{R}(g_i, g_i) = -1$. This forces that the order of $g_i$ must be even. It is immediate by Lagrange's theorem that the order of $G$ is even. Now we have proved (1) and (2). For (3), just note that the space of $\text{gr}(H)$ spanned by group-likes and skew-primitives is equivalent to the space spanned by vertices and arrows of $Q$. Now by Proposition 6.1 $\text{gr}(H)$ is generated by its group-like and skew-primitive elements, hence it is contained in the sub algebra of $kQ$ generated by vertices and arrows. Along with the first paragraph, we have (3). We are done. 

\[\square\]

6.3. As a direct consequence we give an explicit description for coradically graded finite-dimensional coquasitriangular pointed Hopf algebras via generators and defining relations.

Corollary 6.3. Let $H$ be a coradically graded finite-dimensional pointed Hopf algebra with coquasitriangular structure $\mathcal{R}$. Assume that it is connected and its group of group-likes $G$ is not the unit group. Then there exist a generating set $\{g_i| i = 1, \ldots, t\}$ of the group $G$ and for each $g_i$ a set of $(1, g_i)$-primitive elements $\{x_{i,i'}| i' = 1, \ldots, R_i\}$ such that $H$ is generated by $\{g_i, x_{i,i'}| i = 1, \ldots, t; i' = 1, \ldots, R_i\}$ with defining relations

\begin{align}
(6.1) & \quad \text{the defining relations of } G \text{ by the } g_i's, \\
(6.2) & \quad x_{j,j'}g_i = \mathcal{R}(g_i, g_j)g_{j}x_{j,j'}, \forall i, j, j', \\
(6.3) & \quad x_{i,i'}^2 = 0, \forall i, i', \\
(6.4) & \quad x_{j,j'}x_{i,i'} = \mathcal{R}(g_i, g_j)x_{i,i'}x_{j,j'}, \forall i, i', j, j'.
\end{align}

Moreover, $H$ has a PBW type basis

\[\{g^{\sigma_{1,1}}_{x_{1,R_1}} \cdots x_{1,R_1}^{\sigma_{1,R_1}} \cdots x_{t,1}^{\sigma_{t,1}} \cdots x_{t,R_t}^{\sigma_{t,R_t}}|g \in G, \sigma_{i,i'} = 0, 1\}.\]

Proof. Note that Proposition 3.4 can be established for our case directly, and so there is no harm to assume that $\mathcal{R}$ concentrates at degree 0. By Proposition 6.2, there is a Hopf quiver $Q = Q(G, R)$ with $R = \sum_{i=1}^{t} R_i g_i$ such that $H$ is isomorphic to the sub Hopf algebra of the coquasitriangular Hopf algebra $kQ$, determined by the bicharacter $\mathcal{R}$ as in Theorem 3.3, generated by vertices and arrows. Denote by $\{x_{i,i'}| i' = 1, \ldots, R_i\}$ the set of arrows with source 1 and target $g_i$ which are $(1, g_i)$-primitive elements. Since any arrow of $Q$ can be obtained as the ones with source 1 multiplied by group-like elements, hence $H$ is generated by $\{g_i, x_{i,i'}| i = 1, \ldots, t; i' = 1, \ldots, R_i\}$. Just as the arguments in Section 5, it is easy to verify that they satisfy the relations (6.1)-(6.4). So as a linear space $H$ is spanned by the set

\[\{g^{\sigma_{1,1}}_{x_{1,R_1}} \cdots x_{1,R_1}^{\sigma_{1,R_1}} \cdots x_{t,1}^{\sigma_{t,1}} \cdots x_{t,R_t}^{\sigma_{t,R_t}}|g \in G, \sigma_{i,i'} = 0, 1\}.\]

Note that this set is linearly independent, as is clear by straightforward computation using the multiplication formula (2.10). On the other hand, by a standard application of Bergman’s diamond lemma [6], the algebra
generated by \( \{ g_i, x_{i,i'} | i = 1, \ldots, t; i' = 1, \ldots, R_i \} \) with defining relations 
(6.1)-(6.4) has the aforementioned set as a basis. It follows that (6.1)-(6.4)
are sufficient defining relations for \( H \). Now the proof is finished. \( \square \)

6.4. With a help of the lifting theorem of Andruskiewitsch and Schneider
[2] (Theorem 5.5, see also [4]), now we are ready to classify finite-dimensional
coquasitriangular pointed Hopf algebras.

**Theorem 6.4.** Let \( (H, R) \) be a finite-dimensional coquasitriangular pointed
Hopf algebra. Assume that it is connected and its group of group-likes \( G \)
is not the unit group. Then there exist a generating set \( \{ g_i | i = 1, \ldots, t \} \)
of the group \( G \) and for each \( g_i \) a set of \( (1, g_i) \)-primitive elements \( \{ x_{i,i'} | i' = 1, \ldots, R_i \} \) such that \( H \) is generated by \( \{ g_i, x_{i,i'} | i = 1, \ldots, t; i' = 1, \ldots, R_i \} \) with defining relations

\[
(6.5) \quad \text{the defining relations of } G \text{ by the } g_i \text{s},
\]
\[
(6.6) \quad x_{j,j'}g_i = R(g_i, g_j)g_i x_{j,j'}, \forall i, j, j',
\]
\[
(6.7) \quad x_{i,i'}^2 = \mu_{i,i'}(1 - g_i^2), \forall i, i',
\]
\[
(6.8) \quad x_{j,j'}x_{i,i'} - R(g_i, g_j)x_{i,i'}x_{j,j'} = \lambda_{i,i',j,j'}(1 - g_i g_j), \forall (i, i') \neq (j, j').
\]

Here \( \mu_{i,i'} \) and \( \lambda_{i,i',j,j'} \) are some appropriate constants in the field \( k \). Moreover, \( H \) has a PBW type basis
\[
\{ gx_{1,i,1} \cdots x_{1,R_1} \cdots x_{t,1} \cdots x_{t,R_t} | g \in G, \sigma_{i,i'} = 0, 1 \}.
\]

**Proof.** By assumption \( (\text{gr}(H), \text{gr}(R)) \) satisfies the condition of Corollary 6.3, hence it can be presented by generators with relations as given there. Now the theorem follows from the lifting theorem of Andruskiewitsch and Schneider. For the convenience of the reader, we include a detailed proof.

Clearly, the coradical \( H_0 \) is the sub Hopf algebra generated by \( \{ g_i | i = 1, \ldots, t \} \). By Lemma 6.1 in [4], there are elements \( \{ x_{i,i'} | i' = 1, \ldots, R_i \} \in H \)
corresponding to \( \{ x_{i,i'} | i' = 1, \ldots, R_i \} \in \text{gr}(H) \) and they satisfy
\[
\Delta(x_{i,i'}) = g_i \otimes x_{i,i'} + x_{i,i'} \otimes 1, \quad x_{j,j'}g_i = R(g_i, g_j)g_i x_{j,j'}
\]
for any \( i, i', j, j' \). Since \( \text{gr}(H) \) is generated by group-like elements and skew primitive elements, we know \( H \) is indeed generated by \( \{ g_i, x_{i,i'} | i = 1, \ldots, t; i' = 1, \ldots, R_i \} \). For any \( i, i', j, j' \), direct computations show that the element \( x_{i,i'}^2 \) is a \((1, g_i^2)\)-primitive element and \( x_{j,j'}x_{i,i'} - R(g_i, g_j)x_{i,i'}x_{j,j'} \)
is a \((1, g_i g_j)\)-primitive element.

**Claim.** For any \( i, j \in \{ 1, \cdots, t \} \), there are no non-trivial \( (1, g_i^2) \)-primitive elements and no non-trivial \( (1, g_i g_j) \)-primitive elements.

Here the trivial \((1, g)\)-primitive elements are define to be the elements belonging to the space spanned by \( 1 - g \). Otherwise, assume \( y_i \) is a non-trivial \((1, g_i^2)\)-primitive element. By \( g_i x_{i,i'} g_i^{-1} = R(g_i, g_i)x_{i,i'} = -x_{i,i'} \),
\[
g_i^2 x_{i,i'} g_i^{-2} = R(g_i, g_i^2)x_{i,i'} = x_{i,i'}. \quad \text{Thus } R(g_i, g_i^2) = 1 \text{ and so }
\]
\[
R(g_i^2, g_i)R(g_i^2, g_i) = R(g_i^2, g_i^2) = 1.
\]
Note that we always have \( g_i^2 y_i g_i^{-2} = R(g_i^2, g_i^2)y_i = -y_i \) which implies \( R(g_i^2, g_i^2) = 1 \). It’s a contradiction. Similarly, assume that \( z \) is a non-trivial \((1, g_i g_j)\)-primitive element, then

\[
\begin{align*}
g_i g_j z (g_i g_j)^{-1} &= R(g_i g_j, g_j)(g_i g_j) z \\
&= R(g_j, g_j)R(g_i, g_i)R(g_i, g_j)R(g_j, g_i) z \\
&= (-1)^2 z = z.
\end{align*}
\]

Here we have used the fact that \( R \) is skew-symmetric. Thus this also implies that \( R(g_i g_j, g_i g_j) = 1 \). This contradicts to \( R(g_i g_j, g_i g_j) = -1 \) by Proposition 6.2 (2).

Therefore, by the claim above, there are \( \mu_{i, i'}, \lambda_{i, i', j, j'} \in k \) such that

\[
\begin{align*}
x_{i, i'}^2 &= \mu_{i, i'}(1 - g_i^2), \quad x_{j, j'} x_{i, i'} - R(g_i, g_j) x_{i, i'} x_{j, j'} = \lambda_{i, i', j, j'}(1 - g_i g_j).
\end{align*}
\]

Consider a Hopf algebra \( A \) which is generated by group-like elements \( \{ g_i | i = 1, \cdots, t \} \) and for each \( g_i \) a set of \((1, g_i)\)-primitive elements \( \{ x_{i, i'} | i' = 1, \cdots, R_i \} \) and assume it satisfies the relations (6.5)-(6.8). The preceding discussions imply that there is a surjective Hopf algebra map from \( A \) to \( H \). By comparing the dimensions, this surjective map is indeed an isomorphism. \( \square \)

We remark that, by carrying out the same computational process as the examples in Subsections 5.3 and 5.4, it is not difficult to determine all the possible coquasitriangular structures of the coquasitriangular pointed Hopf algebras we have just classified. This is left for the interested reader.

Acknowledgements: The research was supported by the NSF of China (10601052, 10801069). Part of the work was done while the first author was visiting the Abdus Salam International Centre for Theoretical Physics (ICTP). He expresses his sincere gratitude to the ICTP for its support. Both authors would like to thank the DAAD for financial support which enables them to visit the University of Cologne.
