Temporal Logic Trees for Model Checking and Control Synthesis of Uncertain Discrete-time Systems

Yulong Gao, Alessandro Abate, Frank J. Jiang, Mirco Giacobbe, Lihua Xie, and Karl H. Johansson

Abstract—We propose algorithms for performing model checking and control synthesis for discrete-time uncertain systems under linear temporal logic (LTL) specifications. We construct temporal logic trees (TLT) from LTL formulae via reachability analysis. In contrast to automaton-based methods, the construction of the TLT is abstraction-free for infinite systems, that is, we do not construct discrete abstractions of the infinite systems. Moreover, for a given transition system and an LTL formula, we prove that there exist both a universal TLT and an existential TLT via minimal and maximal reachability analysis, respectively. We show that the universal TLT is an underapproximation for the LTL formula and the existential TLT is an overapproximation. We provide sufficient conditions and necessary conditions to verify whether a transition system satisfies an LTL formula by using the TLT approximations. As a major contribution of this work, for a controlled transition system and an LTL formula, we prove that a controlled TLT can be constructed from the LTL formula via control-dependent reachability analysis. Based on the controlled TLT, we design an online control synthesis algorithm, under which a set of feasible control inputs can be generated at each time step. We also prove that this algorithm is recursively feasible. We illustrate the proposed methods for both finite and infinite systems and highlight the generality and online scalability with two simulated examples.

I. INTRODUCTION

In the recent past the integration of computer science and control theory has promoted the development of new areas such as embedded systems design [1], hybrid systems theory [2], and, more recently, cyber-physical systems [3]. Given a model of a dynamical process and a specification (i.e., a description of desired properties), two fundamental problems arise:

- model checking: automatically verifying whether the behavior of the model satisfies the given specification;
- formal control synthesis: automatically designing controllers (inputs to the system) so that the behavior of the model provably satisfies the given specification.

Both problems are of great interest in disparate and diverse applications, such as robotics, transportation systems, and safety-critical embedded system design. However, they are challenging problems when considering dynamical systems affected by uncertainty, and in particular uncertain infinite (uncountable) systems under complex, temporal logic specifications. In this paper, we provide solutions to the model checking and formal control synthesis problems, for discrete-time uncertain systems under linear temporal logic (LTL) specification.

A. Related Work

In general, LTL formulae are expressive enough to capture many important properties, e.g., safety (nothing bad will ever happen), liveness (something good will eventually happen), and more complex combinations of Boolean and temporal statements [4].

In the area of formal verification, a dynamical process is by and large modeled as a finite transition system. A typical approach to both model checking and control synthesis for a finite transition system and an LTL formula leverages automata theory. It is known that each LTL formula can be transformed to an equivalent automaton [5]. The model checking problem can be solved by verifying whether the intersection of the trace set of the transition system and the set of accepted languages of the automaton expressing the negation of the LTL formula is empty, or not [4]. The control synthesis problem can be solved by the following steps: (1) translate the LTL formula into a deterministic automaton; (2) build a “product automaton” between the transition system and the obtained automaton; (3) transform the product automaton into a game [6]; (4) solve the game [7], [8], [9]; and (5) map the solution into a control strategy.

In recent years, the study of model checking and control synthesis for dynamical systems with continuous (uncountable) spaces, which extends the standard setup in formal verification, has attracted significant attention within the control community. This has enabled the formal control synthesis for interesting properties, which are more complex than the usual control objectives such as stability and set invariance. In order to adapt automaton-based methods to infinite systems, abstraction plays a central role in both model checking and control synthesis, which entails: (1) to abstract an infinite system to a finite transition system; (2) to conduct automaton-based model checking or control synthesis for the finite transition system; (3) if a solution is found, to map it back to the infinite system; otherwise, to refine the finite transition system and repeat the steps above.

In order to show the correctness of the solution obtained from the abstracted finite system over the infinite system, an equivalence or inclusion relation between the abstracted finite system and the infinite system needs to be established [10].
Relevant notions include (approximate) bisimulations and simulations. These relations and their variants have been explored for systems that are incrementally (input-to-state) stable [11], [12], or systems with similar properties [13]. Recent work [14] shows that the condition of approximate simulation can be relaxed to controlled globally asymptotic or practical stability with respect to a given set for nonlinear systems. We remark that such condition holds for only a small class of systems in practice.

Based on abstractions, the problem of model checking for infinite systems has been studied in [15], [16]. In [15], it is shown that model checking for discrete-time, controllable, linear systems from LTL formulae is decidable through an equivalent finite abstraction. In [16], the authors study the problem of verifying whether a linear system with additive uncertainty from some initial states satisfies a fragment of LTL formulae, which can be transformed to a deterministic Büchi automaton. The key idea is to use a formula-guided method to construct and refine a finite system abstracted from the linear system and guarantee their equivalence. Along the same line, the problem of control synthesis has also been widely studied for linear systems [17], nonlinear systems [18], stochastic systems [19], hybrid systems [20], and stochastic hybrid systems [21]. The applications of control synthesis under LTL specifications include single-robot control in dynamic environments [22], multi-robot control [23], and transportation control [24].

Beyond automata-based methods, alternative attempts have been made for specific model classes. Receding horizon methods are used to design controllers under LTL for deterministic linear systems [25] and uncertain linear systems [26]. The control of Markov decision processes under LTL is considered in [25] and further applied to multi-robot coordination in [27]. Control synthesis for dynamical systems has been extended also to other specifications like signal temporal logic (STL) [28], and probabilistic computational tree logic (PCTL) [29]. Interested readers may refer to the tutorial paper [30] and the book [31] for detailed discussions.

B. Motivations

Although the last two decades have witnessed a great progress on model checking and control synthesis for infinite systems from both theoretical and practical perspectives, there are some inherent restrictions in the dominant automaton-based methods.

First, abstraction from infinite systems to finite systems suffers from the curse of dimensionality: abstraction techniques usually partition the state space, and transitions are constructed via reachability analysis. The computational complexity increases exponentially with the system dimension. Many works are dedicated to improving the computational efficiency by using overapproximation for (mixed) monotone systems [24], or by exploiting the structure of the uncertainty [21]. However, another issue with abstraction techniques is that only systems with “good properties” (e.g., incremental stability, or smooth dynamics) might admit finite abstractions with guarantees, which limits their generality.

Second, there are few results for handling general LTL formulae when an infinite system comes with uncertainty (e.g., bounded disturbance, or additive noise). In most contributions on control synthesis of uncertain systems, fragments of LTL formulae (e.g., bounded LTL or co-safe LTL) are usually taken into account [32]. [33]. As mentioned before, the LTL formulae are defined over infinite trajectories and it is difficult to control uncertainties propagating along such trajectories. This restriction results from conservative over-approximation in the computation of forward reachable sets, which is widely used for abstraction, and which leads to information loss when used with automaton-based methods.

Third, current methods usually lack online scalability. In many applications, full a priori knowledge of a specification cannot be obtained. For example, consider an automated vehicle required to move from some initial position to some destination without colliding into any obstacle (e.g., other vehicles and pedestrians). Since the trajectories of other vehicles and pedestrians cannot be accurately predicted, we cannot in advance define a specification that captures all the possibilities during the navigation process. Thus, offline design of automaton-based methods is significantly restricted.

Finally, the controller obtained from automaton-based methods usually only contains a single control policy. In some applications, e.g., human-in-the-loop control [34], [35], a set of feasible control inputs are needed to provide more degrees of freedom in the actual implementation. For example, [34] studies a control problem where humans are given a higher priority than the automated system in the decision making process. A controller is designed to provide a set of admissible control inputs with enough degrees of freedom to allow the human operator to easily complete the task.

C. Contributions

Motivated by the above, this paper studies LTL model checking and reachability-based control synthesis for discrete-time uncertain systems. There are many results for reachability analysis on infinite systems [36], [37] and the computation of both forward and backward reachable sets has been widely studied [38], [39], [40]. The connection between STL and reachability analysis is studied in [41], which inspires our work. The main contributions of this paper are three-fold:

1. We construct tree structures from LTL formulae via reachability analysis over dynamical models. We denote the tree structure as a temporal logic tree (TLT). The connection between TLT and LTL is shown to hold for both uncertain finite and infinite models. The construction of the TLT is abstraction-free for infinite systems and admits online implementation, as demonstrated in Section VI. More specifically, given a system and an LTL formula, we prove that both a universal TLT and an existential TLT can be constructed for the LTL formula via minimal and maximal reachability analysis, respectively (Theorems III.1 and III.2). We also show that the universal TLT is an underapproximation for the LTL formula and the existential TLT is an overapproximation for the LTL formula. Our formulation does not restrict the generality of LTL formulae.
A transition system illustrating a traffic light example. Labels are true, ϕ, and false. We conclude the paper with a discussion about our work and our approaches with two numerical examples. In Section VII, we provide applications to show the scalability of our methods. We note that this algorithm is recursively feasible (Theorem V.2). We synthesize a control for over-approximating the satisfaction set, or alternatively using existential TLTs for under-approximating the satisfaction set, or alternatively using existential TLTs for LTL formula by using universal TLTs for under-approximating time dynamical systems using TLTs. We provide sufficient conditions by using existential TLTs. (3) As a core and novel contribution of this work, we provide applications to show the scalability of our methods.

Fig. 1: (a) A transition system illustrating a traffic light example. (b) A TLT corresponding to an LTL formula \( \varphi = \square \varphi \lor g \) for this system. Note that \( \varphi \lor \varphi = \varphi \).

(2) We provide a method for model checking of discrete-time dynamical systems using TLTs. We provide sufficient conditions to verify whether a transition system satisfies an LTL formula by using universal TLTs for under-approximating the satisfaction set, or alternatively using existential TLTs for over-approximating the violation set (Theorem IV.1). Dually, we provide necessary conditions by using existential TLTs for over-approximating the satisfaction set, or alternatively using universal TLTs for under-approximating the violation set (Theorem IV.2).

(3) As a core and novel contribution of this work, we detail an approach for online control synthesis for a controlled transition system to guarantee that the controlled system will satisfy the specified LTL formula. Given a control system and an LTL formula, we construct a controlled TLT (Theorem IV.1). Based on the obtained TLT, we design an online control synthesis algorithm, under which a set of feasible control inputs is generated at each time step (Algorithm 3). We prove that this algorithm is recursively feasible (Theorem V.2). We provide applications to show the scalability of our methods.

D. Organization

The remainder of the paper is organized as follows. In Section II we define the notion of transition system, recall the problem of reachability analysis, and provide preliminaries on LTL specifications. In Section III, we introduce TLT structures and show how to construct a TLT from a given LTL formula. In Section IV, we solve the LTL model checking problem through the constructed TLT. Section V solves the TLT control synthesis problem. In Section VI, we illustrate the effectiveness of our approaches with two numerical examples. In Section VII, we conclude the paper with a discussion about our work and future directions.

II. PRELIMINARIES

This section will first introduce transition systems and then recall reachability analysis and LTL.

A. Transition System

Definition II.1. A transition system TS is a tuple TS = (S, →, S0, AP, L) consisting of

- a set \( S \) of states;
- a transition relation \( \rightarrow \subseteq S \times S \);\footnote{Here, the transition relation is not a functional relation, but instead for some state \( x \), there may exist two different states \( x' \) and \( x'' \) such that \( x \rightarrow x' \) and \( x \rightarrow x'' \) hold. For notational simplicity, we use \( \rightarrow \subseteq S \times S \), rather than \( \rightarrow \subseteq S \times S \). The same claim holds for the controlled transition systems in Section V.}
- a set \( S_0 \subseteq S \) of initial states;
- a set \( AP \) of atomic propositions;
- a labelling function \( L : S \to 2^{AP} \).

Definition II.2. A transition system TS is said to be finite if \( |S| < \infty \) and \( |AP| < \infty \).

Definition II.3. For \( x \in S \), the set \( \text{Post}(x) \) of direct successors of \( x \) is defined by \( \text{Post}(x) = \{ x' \in S \mid x \rightarrow x' \} \).

Definition II.4. A transition system TS is said to be deterministic if \( |S_0| = 1 \) and \( |\text{Post}(x)| = 1 \), \( \forall x \in S \).

Definition II.5. (Trajectory) For a transition system TS, an infinite trajectory \( p \) starting from \( x_0 \) is a sequence of states \( p = x_0 x_1 \ldots x_k x_{k+1} \ldots \) such that \( \forall k \in \mathbb{N}, x_{k+1} \in \text{Post}(x_k) \).

Denote by \( \text{Trajs}(x_0) \) the set of infinite trajectories starting from \( x_0 \). Let \( \text{Trajs}(TS) = \cup_{x \in S_0} \text{Trajs}(x) \). For a trajectory \( p \), the \( k \)-th state is denoted by \( p[k] \), i.e., \( p[k] = x_k \) and the \( k \)-th prefix is denoted by \( p[..k] \), i.e., \( p[..k] = x_0 \ldots x_k \).

Example II.1. A traffic light can be red, green, yellow or black (not working). The traffic light might stop working at any time. After it has been repaired, it turns red. Initially, the light is red. An illustration of such a traffic light is shown in Fig. 2(a). We can model the traffic light as a transition system \( TS = (S, \rightarrow, S_0, AP, L) \):

- \( S = \{ 1, 2, 3, 4, 5 \} \);
- \( \rightarrow = \{ (1, 2), (2, 3), (3, 4), (4, 1), (1, 5), (2, 5), (3, 5), (4, 5), (5, 1) \} \);
- \( S_0 = \{ 1 \} \);
- \( AP = \{ r, y, g \} \);
- \( L = \{ 1 \rightarrow \{ r \}, 2 \rightarrow \{ r, y \}, 3 \rightarrow \{ g \}, 4 \rightarrow \{ y \}, 5 \rightarrow \{ b \} \} \).

\[ \]

Remark II.1. We can rewrite the following discrete-time autonomous system as an infinite transition system:

\[
S : \begin{cases}
x_{k+1} = f(x_k, w_k), \\
y_k = g(x_k),
\end{cases}
\]

where \( x_k \in \mathbb{R}^{n_x}, w_k \in \mathbb{R}^{n_w}, y_k \in \mathbb{R}^O, f : \mathbb{R}^{n_x} \times \mathbb{R}^{n_w} \to \mathbb{R}^{n_x}, \) and \( g : \mathbb{R}^{n_x} \to \mathbb{R}^O \). Here, \( O \) denotes the set of observations. At each time instant \( k \), the disturbance \( w_k \) belongs to a compact set \( \mathbb{W} \subseteq \mathbb{R}^{n_w} \). Denote by \( \text{Ini} \subseteq \mathbb{R}^{n_x} \) the set of initial states. If \( O \) is finite, the system \( S \) can be rewritten as an infinite transition system \( TS_S = (S, \rightarrow, S_0, AP, L) \) with

- \( S = \mathbb{R}^{n_x} \);
- \( \forall x, x' \in S, x \rightarrow x' \) if and only if there exists \( w \in \mathbb{W} \) such that \( x' = f(x, w) \);
- \( S_0 = \text{Ini} \);
- \( AP = O \);
- \( L = g \).

Notice that a trajectory \( p = x_0 x_1 \ldots x_k x_{k+1} \ldots \) is different from a trace, which is the sequence of corresponding sets of atomic propositions, and is denoted by \( L(x_0) L(x_1) \ldots L(x_k) L(x_{k+1}) \ldots \).
B. Reachability Analysis

This subsection specifies the reachability analysis for a transition system TS. We first define the minimal reachable set and the maximal reachable set.

**Definition II.6.** Consider a transition system TS and two sets \( \Omega_1, \Omega_2 \subseteq S \). The k-step minimal reachable set from \( \Omega_1 \) to \( \Omega_2 \) is defined as

\[
R^m(\Omega_1, \Omega_2, k) = \left\{ x_0 \in S \mid \exists p \in \text{Trajs}(x_0), \text{ s.t.,} \right. \\
p \cdot [k] = x_0 \ldots x_k, \forall i \in N_{[0,k-1]}, x_i \in \Omega_1, x_k \in \Omega_2 \}
\]

The minimal reachable set from \( \Omega_1 \) to \( \Omega_2 \) is defined as

\[
R^m(\Omega_1, \Omega_2) = \bigcup_{k \in N} R^m(\Omega_1, \Omega_2, k).
\]

**Lemma II.1.** For two sets \( \Omega_1, \Omega_2 \subseteq S \), define

\[
Q_{k+1} = \{ x \in \Omega_1 \mid \text{Post}(x) \subseteq Q_k \} \cup Q_k,
\]

\( Q_0 = \Omega_2 \).

Then, \( R^m(\Omega_1, \Omega_2) = \lim_{k \to \infty} Q_k \).

**Proof:** From Definition II.6 it is easy to see that

\[
Q_k = \bigcup_{i \in N_{[0,k]}} R^m(\Omega_1, \Omega_2, i).
\]

It follows from the Knaster-Tarski Theorem \([42]\) that \( \lim_{k \to \infty} Q_k \) exists and is a fixed point to the monotone function \( F(\mathbb{P}) = \{ x \in \mathbb{P} \mid \text{Post}(x) \subseteq \mathbb{P} \} \). Thus, we have that \( R^m(\Omega_1, \Omega_2) = \lim_{k \to \infty} Q_k \).

**Definition II.7.** Consider a transition system TS and two sets \( \Omega_1, \Omega_2 \subseteq S \). The k-step maximal reachable set from \( \Omega_1 \) to \( \Omega_2 \) is defined as

\[
R^M(\Omega_1, \Omega_2, k) = \left\{ x_0 \in S \mid \exists p \in \text{Trajs}(x_0), \text{ s.t.,} \right. \\
p \cdot [k] = x_0 \ldots x_N, \forall i \in N_{[0,k-1]}, x_i \in \Omega_1, x_k \in \Omega_2 \}
\]

The maximal reachable set from \( \Omega_1 \) to \( \Omega_2 \) is defined as

\[
R^M(\Omega_1, \Omega_2) = \bigcup_{k \in N} R^M(\Omega_1, \Omega_2, k).
\]

**Lemma II.2.** For two sets \( \Omega_1, \Omega_2 \subseteq S \), define

\[
Q_{k+1} = \{ x \in \Omega_1 \mid \text{Post}(x) \cap Q_k \neq \emptyset \} \cup Q_k,
\]

\( Q_0 = \Omega_2 \).

Then, \( R^M(\Omega_1, \Omega_2) = \lim_{k \to \infty} Q_k \).

**Proof:** Similar to the proof of Lemma II.1.

We define the robust invariant set and the invariant set in the following.

**Definition II.8.** A set \( \Omega_f \subseteq S \) is said to be a robust invariant set of a transition system TS if for any \( x \in \Omega_f \), \( \text{Post}(x) \subseteq \Omega_f \).

**Definition II.9.** For a set \( \Omega \subseteq S \), a set \( \mathcal{RI}(\Omega) \subseteq S \) is said to be the largest robust invariant set in \( S \) if each robust invariant set \( \Omega_f \subseteq \Omega \) satisfies \( \Omega_f \subseteq \mathcal{RI}(\Omega) \).

**Lemma II.3.** For a set \( \Omega \subseteq S \), define

\[
Q_{k+1} = \{ x \in Q_k \mid \text{Post}(x) \subseteq Q_k \},
\]

\( Q_0 = \Omega \).

Then, \( \mathcal{RI}(\Omega) = \lim_{k \to \infty} Q_k \).

**Proof:** It follows again from the Knaster-Tarski Theorem \([42]\) that \( \lim_{k \to \infty} Q_k \) exists and is a fixed point to the monotone function \( F(\mathbb{P}) = \{ x \in \mathbb{P} \mid \text{Post}(x) \subseteq \mathbb{P} \} \). Thus, we have that \( \mathcal{RI}(\Omega) = \lim_{k \to \infty} Q_k \).

**Definition II.10.** A set \( \Omega_f \subseteq S \) is said to be an invariant set of a transition system TS if for any \( x \in \Omega_f \), \( \text{Post}(x) \cap \Omega_f \neq \emptyset \).

**Definition II.11.** For a set \( \Omega \subseteq S \), a set \( \mathcal{I}(\Omega) \subseteq S \) is said to be the largest invariant set in \( S \) if each invariant set \( \Omega_f \subseteq \Omega \) satisfies \( \Omega_f \subseteq \mathcal{I}(\Omega) \).

**Lemma II.4.** For a set \( \Omega \subseteq S \), define

\[
Q_{k+1} = \{ x \in Q_k \mid \text{Post}(x) \cap Q_k \neq \emptyset \},
\]

\( Q_0 = \Omega \).

Then, \( \mathcal{I}(\Omega) = \lim_{k \to \infty} Q_k \).

**Proof:** Similar to the proof of Lemma II.3.

We can understand the reachable sets and invariant sets defined above as maps \( R^m : 2^S \times 2^S \to 2^S \), \( R^M : 2^S \times 2^S \to 2^S \), \( \mathcal{RI} : 2^S \to 2^S \), and \( \mathcal{I} : 2^S \to 2^S \), respectively. In the following, we will refer to them as “reachability operators”.

C. LTL

An LTL formula is defined over a finite set of atomic propositions \( AP \) and both logic and temporal operators. The syntax of LTL can be described as:

\[ \varphi ::= \text{true} \mid a \in AP \mid \neg \varphi_1 \mid \varphi_1 \land \varphi_2 \mid \lor \varphi_1 \mid \varphi_1 U \varphi_2, \]

where \( \lor \) and \( U \) denote the “next” and “until” operators, respectively. By using the negation and conjunction operators, we can define disjunction: \( \varphi_1 \lor \varphi_2 = \neg (\varphi_1 \land \neg \varphi_2) \). By employing the until operator, we can define: (1) eventually, \( \varphi = \varphi \lor \varphi_2 \) (2) always, \( \varphi = \varphi \lor \neg \varphi \); and (3) weak-until, \( \varphi W \varphi_2 = \varphi_1 U \varphi_2 \lor \Box \varphi_1 \).

**Definition II.12.** (LTL semantics) For an LTL formula \( \varphi \) and a trajectory \( p \), the satisfaction relation \( p \models \varphi \) is defined as

\[
p \models p \iff p \in L(x_0),
\]

\[
p \models \neg p \iff p \notin L(x_0),
\]

\[
p \models \varphi_1 \land \varphi_2 \iff p \models \varphi_1 \land p \models \varphi_2,
\]

\[
p \models \varphi_1 \lor \varphi_2 \iff p \models \varphi_1 \lor p \models \varphi_2,
\]

\[
p \models \Box \varphi \iff \exists j \in N \text{ s.t. } p[j..] \models \varphi,
\]

\[
p \models \varphi \iff p \models \varphi \text{ or } \Box \varphi,
\]

\[
p \models \varphi \lor \varphi_2 \iff \exists j \in N \text{ s.t. } p[j..] \models \varphi_1,
\]

\[
p \models \varphi \land \varphi_2 \iff \forall j \in N \text{ s.t. } p[j..] \models \varphi.
\]
A complete path of a TLT is a sequence and control synthesis in the following. Important role when simplifying the TLT for model checking fragment for a TLT. Minimal Boolean fragments play an important role.

**III. TEMPORAL LOGIC TREES**

This section will introduce the notion of TLT and establish a satisfaction relation between a trajectory and a TLT. Then, we construct TLTs from LTL formulae and discuss the approximation relation between them.

### A. Definitions

**Definition III.1.** A TLT is a tree for which the next holds:
- each node is either a set node, a subset of $S$, or an operator node, from $\{\land, \lor, \Box, \Diamond, \emptyset, \top\}$;
- the root node and the leaf nodes are set nodes;
- if a set node is not a leaf node, its unique child is an operator node;
- the children of any operator node are set nodes.

Next we define the complete path and the minimal Boolean fragment for a TLT. Minimal Boolean fragments play an important role when simplifying the TLT for model checking and control synthesis in the following.

**Definition III.2.** A complete path of a TLT is a sequence of nodes and edges from the root node to a leaf node. Any subsequence of a complete path is called a fragment of the complete path.

**Definition III.3.** A minimal Boolean fragment of a complete path is one of the following fragments:

(i) a fragment from the root node to the first Boolean operator node ($\land$ or $\lor$) in the complete path;
(ii) a segment from one Boolean operator node to the next Boolean operator node in the complete path;
(iii) a fragment from the last Boolean operator node of the complete path to the leaf node;

**Example III.1.** Consider the traffic light in Example III.1 and the TLT in Fig. 1(b), which corresponds to the LTL formula $\varphi = \Box \Diamond (g \lor b)$ (the formal construction of a TLT from an LTL formula will be detailed in next subsection). We encode one of the complete paths of this TLT in the form of $x_0 \Box x_1 \lor x_2 \lor x_3$, where $x_0 = x_1 = \{1, 2, 3, 4, 5\}$, $x_2 = \{3, 5\}$, and $x_3 = \{3\}$. For this complete path, the minimal Boolean fragments consist of $x_0 \Box x_1 \lor x_2 \lor x_3$, which correspond to cases (i) and (iii) in Definition III.3 respectively.

We now define the satisfaction relation between a given trajectory and a complete path of a TLT.

**Definition III.4.** Consider a trajectory $p = x_0 x_1 \ldots x_k \ldots$ and encode a complete path of a TLT in the form of $x_0 \odot_1 X_1 \odot_2 \ldots \odot_{N_f} X_{N_f}$, where $N_f$ is the number of operators in the complete path, $X_i \subseteq S$ for all $i \in \mathbb{N}_{[0, N_f]}$, and $\odot_i \in \{\land, \lor, \Box, \Diamond, \emptyset, \top\}$ for all $i \in \mathbb{N}_{[1, N_f]}$. The trajectory $p$ is said to satisfy this complete path if $x_0 \in X_0$ and there exists a sequence of time steps $k_0 k_1 \ldots k_{N_f}$ with $k_i \in \mathbb{N}$ for all $i \in \mathbb{N}_{[0, N_f]}$ and $0 \leq k_0 \leq k_1 \leq k_2 \leq \ldots \leq k_{N_f}$ such that for all $i \in \mathbb{N}_{[0, N_f]}$:

(i) if $\odot_i = \land$ or $\odot_i = \lor$, $x_{k_i} \in X_{i-1}$ and $x_{k_i+1} \in X_i$;
(ii) if $\odot_i = \Box$, $x_{k_i-1} \in X_{i-1}$ and $x_{k_i} \in X_i$;
(iii) if $\odot_i = \Diamond$, $x_j \in X_{i-1}$, $\forall j \geq N_{[k_i-1, k_i-1]}$, and $x_{k_i} \in X_i$;
(iv) if $\odot_i = \Box$, $x_j \in X_i$, $\forall j \geq k_i$.

Consider a $k$-th prefix $p[i:k] = x_0 x_1 \ldots x_k$ from $p$ and a fragment from the complete path in the form of $X_0 \odot_1 X_1 \odot_2 \ldots \odot_{N_f} X_{N_f}$ where $N_f' \leq N_f$. The prefix $p[i:k]$ is said to satisfy this fragment if $x_0 \in X_0$, $x_k \in X_{N_f'}$, and there exists a sequence of time steps $k_0 k_1 \ldots k_{N_f'}$ with $k_i \in \mathbb{N}$ for all $i \in \mathbb{N}_{[0, N_f]}$ and $0 \leq k_0 \leq k_1 \leq k_2 \leq \ldots \leq k_{N_f'} \leq k$, such that for all $i \in \mathbb{N}_{[0, N_f]}$, (i)-(iii) holds and furthermore

(iv') if $\odot_i = \Box$, $x_j \in X_i$, $\forall j \in \mathbb{N}_{[k_i, k_i]}$.

**Definition III.5.** A time coding of a TLT is an assignment of each operator node in the tree to a nonnegative integer.

**Definition III.6.** Consider a trajectory $p = x_0 x_1 \ldots x_k \ldots$ and a TLT. The trajectory $p$ is said to satisfy the TLT if there exists a time coding such that the output of Algorithm 1 is true.

The time coding indicates when the operators in the TLT are activated along a given trajectory. Algorithm 1 provides a procedure to test if a trajectory satisfies a TLT under a given time coding. The TLT is first transformed into a compressed tree, which is analogous to a binary decision diagram (lines 1–2), through Algorithm 2. Then, we check if the trajectory satisfies each complete path of the TLT under the time coding (lines 3–9). Finally, we backtrack the tree with output true or false. If the output is true, the trajectory satisfies the TLT; otherwise, the trajectory does not satisfy the TLT under the given time coding.

Algorithm 2 aims to obtain a tree in a compact form. Each minimal Boolean fragment is encoded according to Definition III.3. The notation $\odot_i$ denotes the operator node and $N_f'$ denotes the number of set nodes in the corresponding minimal Boolean fragment. We compress the sets in the minimal Boolean fragment to be a single set. The simplified tree consists of set nodes and Boolean operator nodes.

**Example III.2.** From Definition III.4, we can verify that the trajectory $p = (1234)\omega$ satisfies the complete path given in Example III.1 by choosing $k_0 = k_1 = 0$ and $k_2 = k_3 = 2$. It follows from Definition III.6 that this trajectory satisfies the corresponding TLT.

**B. Construction and Approximation of TLT**

We define the approximation relations between TLTs and LTL formulae as follows.

**Definition III.7.** A TLT is said to be an under-approximation of an LTL formula $\varphi$ if all the trajectories that satisfy the TLT also satisfy $\varphi$. 

Theorem III.1. For any transition system $TS$ and any LTL formula $\varphi$, 
(i) a TLT can be constructed from the formula $\forall \varphi$ through the reachability operators $R^m$ and $\mathcal{I}$; 
(ii) this TLT is an under-approximation of $\varphi$.

Proof: Here we provide a proof sketch. See Appendix A for a detailed proof.

We prove the constructability by the following three steps: 
(1) we transform the given LTL formula $\varphi$ into an equivalent LTL formula in the weak-until positive normal form; 
(2) for each atomic proposition $a \in AP$, we show that a TLT can be constructed from $\forall a$ (or $\forall \neg a$); 
(3) we leverage induction to show the following: given LTL formulae $\varphi, \varphi_1$, and $\varphi_2$ in weak-until positive normal form, if TLTs can be constructed from $\forall \varphi, \forall \varphi_1$, and $\forall \varphi_2$, respectively, then TLTs can also be constructed through reachability operators $R^m$ and $\mathcal{I}$ from the formulae $\forall (\varphi_1 \land \varphi_2), \forall (\varphi_1 \lor \varphi_2), \forall \bigcirc \varphi, \forall (\varphi_1 \lor \varphi_2)$, and $\forall (\varphi_1 \land \varphi_2)$, respectively.

We follow a similar approach to prove an under-approximation relation between the constructed TLT and the LTL formula. The under-approximation occurs due to the conjunction operator and the presence of branching in the transition system.

Similarly, the following results hold.

Theorem III.2. For any transition system $TS$ and any LTL formula $\varphi$, 
(i) a TLT can be constructed from the formula $\exists \varphi$ through the reachability operators $R^m$ and $\mathcal{I}$; 
(ii) this TLT is an over-approximation of $\varphi$.

Proof: The proof of the first part is similar to that of Theorem III.1 by replacing the universal quantifier $\forall$ and the reachability operators $R^m$ and $\mathcal{I}$ with the existential quantifier $\exists$ and the operators $R^m$ and $\mathcal{I}$, respectively. Also, the proof of the second part is similar to that of Theorem III.1 by following the definition of the maximal reachability analysis.

We call the constructed TLT of $\forall \varphi$ the universal TLT of $\varphi$ and the TLT of $\exists \varphi$ the existential TLT of $\varphi$. We remark that the constructed TLT is not unique: this is because an LTL formula can have different equivalent expressions (e.g., normal forms). Despite this, the approximation relations between an LTL formula and the corresponding TLT still hold.

The following corollary shows that the approximation relation between TLTS and LTL formulae are tight for deterministic transition systems.

Corollary III.1. For any deterministic transition system $TS$ and any LTL formula $\varphi$, the universal TLT and the existential TLT of $\varphi$ are identical.

Proof: If the system is deterministic, it follows from Lemmas III.1 and Lemma III.3.1 that for any $\Omega_1, \Omega_2 \subseteq S$ and $\Omega \subseteq S, R^m(\Omega_1, \Omega_2) = R^m(\Omega_1, \Omega_2)$ and $\mathcal{I}(\Omega) = \mathcal{I}(\Omega)$. Then, by the same construction procedure, we have that the constructed universal TLT is the same as the constructed existential TLT.

Remark III.1. Computation of reachable sets plays a central role in the construction of the TLT. The computation of reachable sets is not the focus of this paper. Interested readers are referred to relevant results [38], [39], [40] and associated
computational tools, e.g., the multi-parametric toolbox [43] and the Hamilton-Jacobi toolbox [44].

Example III.3. Consider the traffic light in Example II.1 and the LTL formula \( \varphi = \Box (g \lor b) \) in Example III.2 again. We follow the proof of Theorem III.2 to show the correspondence between \( \forall \varphi \) and the TLT in Fig. 7(b):

1. the universal TLT of \( g \) is a single set node, i.e., \( \{3\} \) and the universal TLT of \( b \) is also a single set node, i.e., \( \{5\} \);
2. the root node of the universal TLT of \( g \lor b \) is the union of \( \{3\} \) and \( \{5\} \), i.e., \( \{3, 5\} \);
3. the root node of the universal TLT of \( \Box (g \lor b) \) is \( R^m(S, \{3, 5\}) = \{1, 2, 3, 4, 5\} \);
4. the root node of the universal TLT of \( \Diamond (g \lor b) \) is \( R_\forall(S, \{3, 5\}) = \{1, 2, 3, 4, 5\} \).

We can follow the same steps in the proof of Theorem III.2 to construct the existential TLT of \( \varphi \), which is the same as the universal TLT of \( \varphi \) for the system in Example II.1.

IV. Model Checking via TLT

This section focuses on model checking problems.

Problem IV.1. Consider a transition system \( TS \) and an LTL formula \( \varphi \). Verify whether \( TS \models \varphi \), i.e., \( \forall x_0 \in S_0, x_0 \models \varphi \).

Thanks to the approximation relations between the TLTs and the LTL formulae, we obtain the following lemma.

Lemma IV.1. For any transition system \( TS \) and any LTL formula \( \varphi \),

1. \( x_0 \models \forall \varphi \) if \( x_0 \) belongs to the root node of the universal TLT of \( \varphi \);
2. \( x_0 \models \exists \varphi \) only if \( x_0 \) belongs to the root node of the existential TLT of \( \varphi \).

Proof: The first result follows from that the root node of the universal TLT is an under-approximation of the satisfaction set of \( \varphi \), as shown in Theorem III.1. Dually, the second result follows from that the root node of the universal TLT is an over-approximation of the satisfaction set of \( \varphi \), shown in Theorem III.2.

The next theorem provides two sufficient conditions for solving Problem IV.1.

Theorem IV.1. For a transition system \( TS \) and an LTL formula \( \varphi \), \( TS \models \varphi \) if one of the following conditions holds:

1. the initial state set \( S_0 \) is a subset of the root node of the universal TLT for \( \varphi \);
2. no initial state from \( S_0 \) belongs to the root node of the existential TLT for \( \neg \varphi \).

Proof: Condition (i) directly follows from the result of Lemma IV.1. Let us next prove condition (ii). It follows that

\( TS \models \varphi \iff \forall p \in \text{Trajs}(TS), p \models \varphi \iff \forall p \in \text{Trajs}(TS), p \not\models \neg \varphi \).

From the second result of Lemma IV.1 if \( x_0 \) does not belong to the root node of the existential TLT of \( \neg \varphi \), we have \( p \not\models \neg \varphi \), \( \forall p \in \text{Trajs}(x_0) \). Thus, the condition (ii) is sufficient for verifying \( TS \models \varphi \).

Similarly, we derive two necessary conditions for solving the model checking problem.

Theorem IV.2. For a transition system \( TS \) and an LTL formula \( \varphi \), \( TS \models \varphi \) only if one of the following conditions holds:

1. the initial state set \( S_0 \) is a subset of the root node of the existential TLT for \( \varphi \);
2. no initial state from \( S_0 \) belongs to the root node of the universal TLT for \( \neg \varphi \).

Proof: Similar to Theorem IV.1.

Notice that the approximation relations between the TLT and the LTL formula are tight for deterministic transition systems, as shown in Corollary III.1. In this case, the model checking problem can be tackled as follows.

Corollary IV.1. For a deterministic transition system \( TS \) and an LTL formula \( \varphi \), \( TS \models \varphi \) if and only if the initial state set \( S_0 \) is a subset of the root node of the universal (or existential) TLT for \( \varphi \).

Proof: Follows from Corollary III.1.

The conditions in Theorems IV.1 and IV.2 imply that one can directly do model checking by using TLTs, as shown in the following example.

Example IV.1. Let us continue to consider the traffic light and the LTL formula \( \varphi = \Box (g \lor b) \). Let us verify whether \( TS \models \varphi \) by using the above method. Since the unique initial state \( x_0 \) belongs to the root node of the universal TLT of \( \varphi \) shown in Fig. 7(b), it follows from condition (i) in Theorem IV.1 that \( TS \models \varphi \). Next, we show how to use condition (ii) to verify that \( TS \models \varphi \).

First of all, we have \( \neg \varphi = \Box (\neg g \land \neg b) \). Following the proof of Theorem III.2, we construct the existential TLT of \( \neg \varphi \):

1. the existential TLT of \( \neg g \) is a single set node, i.e., \( \{1, 2, 4, 5\} \) and the existential TLT of \( \neg b \) is also a single set node, i.e., \( \{1, 2, 3, 4\} \);
2. the root node of the existential TLT of \( \neg g \land \neg b \) is the intersection of \( \{1, 2, 4, 5\} \) and \( \{1, 2, 3, 4\} \), i.e., \( \{1, 2\} \);
3. the root node of the existential TLT of \( \Box (\neg g \land \neg b) \) is \( I(\{1, 2\}) = \{2, 3, 4, 5\} \).

As the existential TLT of \( \neg \varphi \) is the empty set \( \emptyset \), this implies that condition (ii) in Theorem IV.2 holds and thus \( TS \models \varphi \).

V. Control Synthesis via TLT

This section will show how to use the TLT to do control synthesis. Before that, we will introduce the notion of controlled transition system and recall the controlled reachability analysis.

A. Controlled Transition System

Definition V.1. A controlled transition system \( CTS = (S, U, \rightarrow, S_0, A_P, L) \) consisting of

- a set \( S \) of states;
- a set \( U \) of control inputs;
- a transition relation \( \rightarrow \in S \times \mathbb{U} \times S \);
- a set \( S_0 \) of initial states;
- a set \( A_P \) of propositions.
• a set $\mathcal{AP}$ of atomic propositions;
• a labelling function $L : \mathbb{S} \to 2^{\mathcal{AP}}$.

**Definition V.2.** A controlled transition system $\text{CTS}$ is said to be finite if $|\mathbb{S}| < \infty$, $|\mathbb{U}| < \infty$, and $|\mathcal{AP}| < \infty$.

**Definition V.3.** For $x \in \mathbb{S}$ and $u \in \mathbb{U}$, the set $\text{Post}(x,u)$ of direct successors of $x$ under $u$ is defined by $\text{Post}(x,u) = \{x' \in \mathbb{S} | x \xrightarrow{u} x'\}$.

**Definition V.4.** For $x \in \mathbb{S}$, the set $\mathbb{U}(x)$ of admissible control inputs at state $x$ is defined by $\mathbb{U}(x) = \{u \in \mathbb{U} | \text{Post}(x,u) \neq \emptyset\}$.

**Definition V.5. (Policy)** For a controlled transition system $\text{CTS}$, a policy $\mu = u_0u_1 \ldots u_k \ldots$ is a sequence of maps $u_k : \mathbb{S} \to \mathbb{U}$. Denote by $\mathcal{M}$ the set of all policies.

**Definition V.6. (Trajectory)** For a controlled transition system $\text{CTS}$, an infinite trajectory $p$ starting from $x_0$ under a policy $\mu = u_0u_1 \ldots u_k \ldots$ is a sequence of states $p = x_0x_1 \ldots x_k \ldots$ such that $\forall k \in \mathbb{N}$, $x_{k+1} \in \text{Post}(x_k, u_k(x_k))$. Denote by $\text{Trajs}(x_0, \mu)$ the set of infinite trajectories starting from $x_0$ under $\mu$.

**Example V.1.** A controlled transition system $\text{CTS} = (\mathbb{S}, U, \to, S_0, \mathcal{AP}, L)$ is shown in Fig. 2(a), where

- $\mathbb{S} = \{s_1, s_2, s_3, s_4\}$;
- $\mathbb{U} = \{a_1, a_2\}$;
- $\to = \{(s_1, a_1, s_2), (s_1, a_1, s_3), (s_2, a_1, s_2), (s_2, a_1, s_3), (s_2, a_2, s_2), (s_2, a_2, s_3), (s_1, a_2, s_2), (s_3, a_1, s_3), (s_4, a_2, s_3)\}$;
- $S_0 = \{s_1\}$;
- $\mathcal{AP} = \{a_1, a_2, o_3\}$;
- $L = \{s_1 \to \{a_1\}, s_2 \to \{o_2\}, s_3 \to \{o_3\}, s_4 \to \{o_2\}\}$.

**Remark V.1.** We express the following discrete-time uncertain control system as an infinite controlled transition system:

$$\text{CTS} : \left\{ \begin{align*}
x_{k+1} &= f(x_k, u_k, w_k), \\
y_k &= g(x_k),
\end{align*} \right. \quad (1)$$

where $x_k \in \mathbb{R}^n_x$ and $u_k \in \mathbb{U}^n$, $w_k \in \mathbb{W}^n$, $y_k \in \mathbb{Y}^n$, $f : \mathbb{R}^n_x \times \mathbb{U}^n \times \mathbb{W}^n \to \mathbb{R}^n_x$, and $g : \mathbb{R}^n_x \to \mathbb{Y}^n$. Here, $\mathbb{O}$ denotes the set of observations. At each time instant $k$, the control input $u_k$ is constrained by a compact set $\mathbb{U}^{\text{CS}} \subset \mathbb{R}^n_x$ and the disturbance $w_k$ belongs to a compact set $\mathbb{W}^{\text{CS}} \subset \mathbb{R}^n_w$. Denote by $\text{Ini} \subset \mathbb{R}^n_x$ the set of the initial states. If the observation set $\mathbb{O}$ is finite, $\text{CS}$ can be rewritten as an infinite controlled transition system, $\text{CTS}^{\text{CS}} = (\mathbb{S}, U, \to, S_0, \mathcal{AP}, L)$ where

- $\mathbb{S} = \mathbb{R}^n_x$;
- $\mathbb{U} = \mathbb{U}^{\text{CS}}$;
- $\forall x, x' \in \mathbb{S}$ and $\forall u \in \mathbb{U}, x \xrightarrow{u} x'$ if and only if there exists $w \in \mathbb{W}$ such that $x' = f(x, u, w)$;
- $S_0 = \text{Ini}$;
- $\mathcal{AP} = \mathbb{O}$;
- $L = g$.

**B. Controlled Reachability Analysis**

This subsection will develop reachability analysis of a controlled transition system $\text{CTS}$.

---

![Figure 2](image-url)  
(a) Graph description of a controlled transition system; (b) The controlled TLT of $\varphi = \Box o_2$ for the system.

**Definition V.7.** Consider a controlled transition system $\text{CTS}$ and two sets $\Omega_1, \Omega_2 \subseteq \mathbb{S}$. The $k$-step controlled reachable set from $\Omega_1$ to $\Omega_2$ is defined as

$$\mathcal{R}^c(\Omega_1, \Omega_2, k) = \{x_0 \in \mathbb{S} | \exists \mu \in \mathcal{M} \text{ s.t., } \forall p \in \text{Trajs}(x_0, \mu), p[0..k] = x_0 \ldots x_k, \forall i \in [0..k-1], x_i \in \Omega_1, x_k \in \Omega_2\}.$$

The controlled reachable set from $\Omega_1$ to $\Omega_2$ is defined as

$$\mathcal{R}^c(\Omega_1, \Omega_2) = \bigcup_{k \in \mathbb{N}} \mathcal{R}^c(\Omega_1, \Omega_2, k).$$

**Lemma V.1.** For two sets $\Omega_1, \Omega_2 \subseteq \mathbb{S}$, define

$$Q_{k+1} = \{x \in \Omega_1 | \exists u \in \mathbb{U}(x), \text{Post}(x,u) \subseteq Q_k\} \cup Q_k,$$

$$Q_0 = \Omega_1.$$

Then, $\mathcal{R}^c(\Omega_1, \Omega_2) = \lim_{k \to \infty} Q_k$.

**Proof:** Similar to the proof of Lemma II.1.

**Definition V.8.** A set $\Omega_f \subseteq \mathbb{S}$ is said to be a robust controlled invariant set (RCIS) of a transition system $\text{TS}$ if for any $x \in \Omega_f$, there exists $u \in \mathbb{U}(x)$ such that $\text{Post}(x,u) \subseteq \Omega_f$.

**Definition V.9.** For a set $\Omega \subseteq \mathbb{S}$, a set $\text{RCI}(\Omega) \subseteq \mathbb{S}$ is said to be the largest RCIS in $\mathbb{S}$ if each RCIS $\Omega_f \subseteq \Omega$ satisfies $\Omega_f \subseteq \text{RCI}(\Omega)$.

**Lemma V.2.** For a set $\Omega \subseteq \mathbb{S}$, define

$$Q_{k+1} = \{x \in \Omega_k | \exists u \in \mathbb{U}(x), \text{Post}(x,u) \subseteq Q_k\},$$

$$Q_0 = \Omega.$$

Then, $\text{RCI}(\Omega) = \lim_{k \to \infty} Q_k$.

**Proof:** Similar to the proof of Lemma II.3.

The definitions of controlled reachable sets and RCISs provide us a way to synthesize the feasible control set, which is detailed in Algorithm 4. In the following, we treat the maps $\mathcal{R}^c : 2^S \times 2^S \to 2^S$ and $\text{RCI} : 2^S \to 2^S$ as the reachability operators.
C. Construction and Approximation of TLT

The next theorem shows how to construct a TLT from an LTL formula for a controlled transition system and discusses its approximation relation.

**Theorem V.1.** For a controlled transition system CTS and any LTL formula $\varphi$, the following holds:

(i) a TLT can be constructed from the formula $\varphi$ through the reachability operators $R^c$ and $RCI$;

(ii) given an initial state $x_0$, if there exists a policy $\mu$ such that $p$ satisfies the constructed TLT, $\forall p \in \text{Trajs}(x_0, \mu)$, then $p \models \varphi$, $\forall p \in \text{Trajs}(x_0, \mu)$.

**Proof:** The proof of the first part is similar to that of Theorem III.1 by replacing the reachability operators $R^m(\cdot)$ and $RI(\cdot)$ with $R^c(\cdot)$ and $RCI(\cdot)$, respectively.

Similar to the under-approximation of the universal TLT in Theorem III.1 we can show that the path satisfying the constructed TLT in the first part also satisfies the LTL formula. Then, we can directly prove the second result.

Let us call the constructed TLT of $\varphi$ in Theorem V.1 the controlled TLT of $\varphi$.

**Remark V.2.** Checking whether there exists a policy, such that all the resulting trajectories satisfy the obtained controlled TLT, is in general a hard problem. A straightforward necessary condition is that $x_0$ belongs to the root node of the controlled TLT; however, this is neither a necessary nor a sufficient condition on the existence of a policy such that all the resulting trajectories satisfy the given LTL formula. A (rather conservative) necessary condition for the latter case can be obtained by regarding the controlled TS as a non-deterministic transition system, and then applying Thereom IV.2.

Next we will show how to construct the controlled TLT through an example.

**Example V.2.** Consider the controlled transition system in Example IV.1. For an LTL formula $\varphi = \diamond \Box \sigma_2$, we can follow the steps in the proof of Theorem IV.1 to construct the controlled TLT of $\varphi$, as shown in Fig. 2(b).

D. Control Synthesis Algorithm

In this subsection, we solve the following control synthesis problem.

**Problem V.1.** Consider a controlled transition system CTS and an LTL formula $\varphi$. For an initial state $x_0 \in S_0$, find, whenever existing, a sequence of control inputs $u = u_0(x_0)u_1(x_1) \ldots u_k(x_k)$ such that the resulting trajectory $p = x_0x_1 \ldots x_k$ satisfies $\varphi$.

**Remark V.3.** Note that the objective of the above problem is not to find a policy $\mu$, but a sequence of control inputs that depend on the measured state. In general, synthesizing a policy $\mu$ such that each trajectory $p \in \text{Trajs}(x_0, \mu)$ satisfies $\varphi$ is computationally intractable for infinite systems. Instead, here we seek to find online a feasible control input at each time step, in a similar spirit to constrained control or receding horizon control.

Instead of directly solving Problem V.1 we consider the following related task, whose solution is also a solution to Problem V.1 thanks to Theorem V.1.

**Problem V.2.** Consider a controlled transition system CTS and an LTL formula $\varphi$. For an initial state $x_0 \in S_0$, find, whenever existing, a sequence of control inputs $u = u_0(x_0)u_1(x_1) \ldots u_k(x_k)$ such that the resulting trajectory $p = x_0x_1 \ldots x_k$ satisfies the controlled TLT constructed from $\varphi$.

Algorithm 3 provides a solution to Problem V.2. In particular, Algorithm 3 presents an online feedback control synthesis procedure, which consists of three steps: (1) control tree: replace each set node of the TLT with a corresponding control set candidate (Algorithm 4); (2) compressed control tree: compress the control tree as a new tree whose set nodes are control sets and whose operator nodes are conjunctions and disjunctions (Algorithm 2); (3) backtrack on the control sets through a bottom-up traversal over the compressed control tree (Algorithm 5). If the output of Algorithm 5 is $\text{NExis}$, there does not exist a feasible solution to Problem V.2. We remark that Algorithm 3 is implemented in a similar way to receding horizon control with the prediction horizon being one.

**Algorithm 3 Online Feedback Control Synthesis via TLT**

**Input:** an initial state $x_0 \in S_0$ and the controlled TLT of an LTL formula $\varphi$

**Output:** $\text{NExis}$ or $(u, p)$ with $u = u_0u_1 \ldots u_k$ and $p = x_0x_1 \ldots x_k$

1: initialize $k = 0$
2: construct a control tree via Algorithm 4, with input $p[\ldots k] = x_0 \ldots x_k$ and the TLT;
3: construct a compressed tree via Algorithm 2, with input the control tree;
4: synthesize a control set $\bigcup_k^c(x_k)$ via Algorithm 5, with input the compressed tree;
5: if $\bigcup_k^c(x_k) = \emptyset$ then
6: stop and return $\text{NExis}$;
7: else
8: choose $u_k \in \bigcup_k^c(x_k)$;
9: implement $u_k$ and measure $x_{k+1} \in \text{Post}(x_k, u_k)$;
10: update $k = k + 1$ and go to Step 2;
11: end if

Algorithm 4 aims to construct a control tree that enjoys the same tree structure as the input TLT. The difference is that all the set nodes are replaced with the corresponding control set nodes. The correspondence is established as follows: (1) whether the initial state $x_0$ belongs to the root node or not (lines 1–3); (2) whether the prefix $p[\ldots k]$ satisfies the fragment from the root node to the set node (lines 5–7); (4) whether or not the set node is a leaf node (lines 9–14); (5) which operator the child of the set node is (lines 16–24). Algorithm 5 aims to backtrack a set by using the compressed tree. We update the parent of each Boolean operator node through a bottom-up traversal.

Note that the construction of a control tree in Algorithm 4 is closely related to the controlled reachability analysis in Sec-
Algorithm 4 Control Tree

Input: \( p[.k] = x_0 \ldots x_k \) and a TLT
Output: a control tree

1: if \( k = 0 \) and \( x_0 \notin \) the root node of TLT then
2: return \( \emptyset \)
3: else
4: for each set node \( X \) of TLT through a bottom-up traversal do
5: if \( p[.k] \) does not satisfy the fragment from the root node \( X \) then
6: \( \triangleright \) see Definition [III.2]
7: replace \( X \) with \( \emptyset \);
8: else
9: if \( X \) is leaf node then
10: if the parent of \( X \) is \( \square \) then
11: replace \( X \) with \( \cup \{ u \in U \mid \text{Post}(x_k,u) \subseteq RCI(X) \} \);
12: \( \triangleright \) for each Boolean operator node, \( \mathcal{CH} \) collects its children and \( \cup_{u \in \mathcal{CH}_U} \) is the corresponding control set for each child;
13: replace \( X \) with \( U \);
14: end if
15: else
16: switch the child of \( X \) do
17: case \( \land \) or \( \lor \)
18: replace \( X \) with \( U = \bigcap_{i \in \mathcal{CH}_U} \mathcal{U}_{\mathcal{CH},i} \)
19: \( \triangleright \text{CH collects its children and } \mathcal{U}_{\mathcal{CH},i} \text{ is the corresponding control set for each child;} \)
20: \( \triangleright \mathcal{Y} \text{ is the child of } \square \);
21: replace \( X \) with \( U = \{ u \in U \mid \text{Post}(x_k,u) \subseteq \mathcal{Y} \} \);
22: end if
23: end for
24: return the updated tree as the control tree.

Algorithm 5 Set Backtracking

Input: a compressed tree
Output: a set \( \mathcal{U}_k^* \)

1: for each Boolean operator node of the compressed tree through a bottom-up traversal do
2: switch Boolean operator do
3: case \( \land \)
4: replace its parent with \( \mathcal{Y}_P \cup (\bigcap_{i \in \mathcal{CH}_U} \mathcal{Y}_{\mathcal{CH},i}) \);
5: case \( \lor \)
6: replace its parent with \( \mathcal{Y}_P \cup (\bigcup_{i \in \mathcal{CH}_U} \mathcal{Y}_{\mathcal{CH},i}) \);
7: end for
8: \( \triangleright \text{CH collects its children, and } \mathcal{Y}_{\mathcal{CH},i} \text{ is the corresponding control set for each child;} \)
9: return the root node.
the controlled TLT and the formula ϕ.

In this example, Algorithm 3 is recursively feasible since we can verify that the condition in Theorem VI.2 holds. That is, there exists a policy such that all the resulting trajectories satisfy the controlled TLT: a feasible stationary policy is μ = uu⋯, where u : S → Ω with u(s1) = a1, u(s2) = a2, u(s3) = a1, and u(s4) = a1. Under this policy, there are two possible trajectories, p = s1s3(s2s4)∞ and p = s1(s2s4)∞, both of which satisfy the controlled TLT and the LTL formula ϕ.

VI. EXAMPLES

A. Obstacle Avoidance

Following the example of obstacle avoidance for double integrator in [45], we consider the following dynamical system

\[ x_{k+1} = \begin{bmatrix} 1 & 0.2 \\ 0 & 1 \end{bmatrix} x_k + \begin{bmatrix} 0.1 \\ 0.2 \end{bmatrix} u_k + w_k. \]  

(2)

Different from [45], we choose the smaller sampling time of 0.2 second and take into account the disturbance wk. We consider the same scenario as in [45], as shown in Fig. 3(a). The working space is \( X = \{ z \in \mathbb{R}^2 \mid [-10, -10]^T \leq z \leq [2, 2]^T \} \), the control constraint set is \( \Omega = \{ z \in \mathbb{R} \mid -2 \leq z \leq 2 \} \), and the disturbance set is \( W = \{ z \in \mathbb{R}^2 \mid -0.05 \leq z \leq 0.05 \} \). In Fig. 3(a), the obstacle regions are \( \Omega_1 = \{ z \in \mathbb{R}^2 \mid [-10, -10]^T \leq z \leq [-5, -5]^T \} \) and \( \Omega_2 = \{ z \in \mathbb{R}^2 \mid [-6, -4]^T \leq z \leq [-5, -3]^T \} \), the target region is \( T = \{ z \in \mathbb{R}^2 \mid [-0.5, -0.5]^T \leq z \leq [-0.5, -0.5]^T \} \), and two visiting regions are \( A = \{ z \in \mathbb{R}^2 \mid [-6, -1]^T \leq z \leq [-5, 2]^T \} \) and \( B = \{ z \in \mathbb{R}^2 \mid [-6, -3]^T \leq z \leq [-4, -2]^T \} \).

Recall the system CS [1]. Let the set of the observations be \( \mathcal{O} = \{ a_1, a_2, a_3, a_4, a_5, a_6 \} \) and, if \( x \in X \), we define the observation function as

\[ g(x) = \begin{cases} \{ a_1, a_2 \}, & \text{if } x \in X \cap \Omega_1, \\ \{ a_1, a_3 \}, & \text{if } x \in X \cap \Omega_2, \\ \{ a_1, a_4 \}, & \text{if } x \in X \cap A, \\ \{ a_1, a_5 \}, & \text{if } x \in X \cap B, \\ \{ a_1, a_6 \}, & \text{if } x \in X \cap T, \\ \{ a_1 \}, & \text{otherwise.} \end{cases} \]  

(3)

As shown in Remark VI.1, we can rewrite the system (2) with the observation function (3) as a controlled transition system with the set of atomic propositions \( \mathcal{AP} = \mathcal{O} \) and the labelling function \( L = g \).

### Table I: Online implementation under Algorithm 3

| Time k | State \( s_k \) | Control set \( U_k^c(x_k) \) | Control input \( u_k \) |
|--------|----------------|-----------------------------|------------------------|
| 0      | \( s_1 \)     | \{ a_1 \}                   | a_1                    |
| 1      | \( s_2 \)     | \{ a_1, a_2 \}              | a_2                    |
| 2      | \( s_3 \)     | \{ a_1, a_2 \}              | a_1                    |
| 3      | \( s_4 \)     | \{ a_1, a_2 \}              | a_2                    |

Fig. 3: (a) Scenario of Example 1; (b) The controlled TLT for the LTL formula \( \varphi = ((a_1 \land a_2 \land -a_3) \lor (a_3 \land a_4)) \). In Example 1, where \( Y_0 = Y_1 \cap Y_2 \), \( Y_1 = R^c(X \setminus (\Omega_1 \cup \Omega_2), RC(T)) \), and \( Y_2 = R^c(X \setminus T, A \cup B) \).

Fig. 4: Trajectories starting from the initial states \([1, -5]^T\): (a) state trajectory; (b) control trajectory together with control sets.

Fig. 5: Trajectories starting from the initial states \([-4.5, -2.5]^T\): (a) state trajectory; (b) control trajectory.

Fig. 6: Trajectories starting from the initial states \([0, -2]^T\): (a) state trajectory; (b) control trajectory.
In [45], the specification is to visit the region \( A \) or region \( B \), and then the target region \( T \), while always avoiding obstacles \( O_1 \) and \( O_2 \), and staying inside the working space \( X \). This specification can be expressed as a co-safe LTL formula \( \varphi = ((a_1 \land \neg a_2 \land \neg a_3) \cup a_6) \land (\neg a_6 \cup (a_4 \lor a_5)) \). Here, we extend the specification to be to visit region \( A \) or region \( B \), and then visit and always stay inside the target region \( T \), while always avoiding obstacles \( O_1 \) and \( O_2 \), and staying inside working space \( X \). Obviously, this specification cannot be expressed as a co-safe LTL formula, and thus cannot be handled by the approach in [45]. We instead express this specification as the LTL formula \( \varphi = ((a_1 \land \neg a_2 \land \neg a_3) \cup a_6) \land (\neg a_6 \cup (a_4 \lor a_5)) \). We will show that our approach can handle such non-co-safe LTL formula. By computing inner approximations of the controlled reachable sets, we can construct the controlled TLT of \( \varphi \) and then use Algorithm 3 to synthesize controllers online. The constructed controlled TLT for \( \varphi \) is shown in Fig. 3(b). Similar to [45], we choose three different initial states, for each of which the state trajectories and the control trajectories are shown in Figs. 4-6. We can see that in Figs. 4-6(a), all state trajectories satisfy the required specification \( \varphi \). The black dots are the initial state. In this example, the target region \( T \) is a RCIS. After entering \( T \), the states stay there by using the controllers that ensure robust invariance. In Figs. 4-6(b), the dashed lines denote the control bounds, the cyan regions represent the synthesized control sets in Algorithm 3, and the blue lines are the implemented control inputs.

B. Online Specification Update

This example will show how the specification can be updated online when using our approach. As shown in Fig. 7, we consider a scenario where an automated vehicle plans to move to a target set \( T \) but with some unknown obstacles on the road. The sensing region of the vehicle is limited. We use a single integrator model with a sample period of 1 second to model the dynamics of the vehicle:

\[
x_{k+1} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} x_k + \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} u_k + w_k.
\]

The working space is \( X = \{z \in \mathbb{R}^2 | [0, -5]^T \leq z \leq [150, 5]^T\} \), the control constraint set is \( U = \{z \in \mathbb{R}^2 | [-2, -0.5]^T \leq z \leq [2, 0.5]^T\} \), the disturbance set is \( W = \{z \in \mathbb{R}^2 | [-0.01, -0.1]^T \leq z \leq [0.01, 0.1]^T\} \), and the target region is \( T = \{z \in \mathbb{R}^2 | [145, -5]^T \leq z \leq [150, 0]^T\} \). We assume that \( X, U, \) and \( W \) are known \textit{a priori} to the vehicle and the vehicle should move along the lane with the right direction unless lane change is necessary. In Fig. 7 there are two broken vehicles in the sets \( O_1 = \{z \in \mathbb{R}^2 | [40, -5]^T \leq z \leq [45, 0]^T\} \) and \( O_2 = \{z \in \mathbb{R}^2 | [100, -5]^T \leq z \leq [105, 0]^T\} \). We assume that \( O_1 \) and \( O_2 \) are unknown to the vehicle at the beginning. As long as the vehicle can sense them, they are known to the vehicle.

Let the initial state be \( x_0 = [0.5, -2.5]^T \) and the sensing limitation is 15. At time step \( k = 0 \), the set of observations is \( O = \{a_1, a_2\} \) and if \( x \in X \), we define the observation function as

\[
g(x) = \begin{cases} 
\{a_1, a_2\}, & \text{if } x \in X \cap T, \\
\{a_1\}, & \text{otherwise}.
\end{cases}
\]

The initial specification can be expressed as an LTL \( \varphi = a_1 U a_2 \). By constructing the controlled TLT of \( \varphi \) shown in Fig. 8 and implementing Algorithm 3, we obtain one realization as shown in Fig. 9. We can see that the vehicle keeps moving straightforward until it senses the obstacle \( O_1 \) at \([25.5, -2.4]^T\).

When the vehicle can sense \( O_1 \), a new observation \( a_3 \) with \( a_3 \neq a_1 \) and \( a_3 \neq a_2 \) is added to the set \( O \), which becomes \( O = \{a_1, a_2, a_3\} \). If \( x \in X \), we update the observation function as

\[
g(x) = \begin{cases} 
\{a_1, a_2\}, & \text{if } x \in X \cap T, \\
\{a_1, a_3\}, & \text{if } x \in X \cap O_1, \\
\{a_1\}, & \text{otherwise}.
\end{cases}
\]

To avoid \( O_1 \), the new specification is changed to be \( \varphi' = \varphi \land (\neg a_3) \). We can construct the TLT of \( \varphi' \) based on that of \( \varphi \), which is shown in Fig. 8 and then continue to implement Algorithm 3. We can see that the vehicle changes lane from \([25.5, -2.4]^T\) and quickly merges back after overtaking...
The trajectories are shown in Fig. 9. The vehicle is under the control with respect to $\varphi'$ until it can sense $O_2$ at $[86.3, -2.5]^T$.

Similarly, when the vehicle can sense $O_2$, we update $O = \{a_1, a_2, a_3, a_4\}$ and the observation function as if $x \in X$, $g(x) = \begin{cases} \{a_1, a_2\}, & \text{if } x \in X \cap T, \\ \{a_1, a_3\}, & \text{if } x \in X \cap O_1, \\ \{a_1, a_4\}, & \text{if } x \in X \cap O_2, \\ \{a_1\}, & \text{otherwise}. \end{cases}$

To avoid $O_2$, the new specification is changed to be $\varphi'' = \varphi' \land (\Box \neg a_4)$. We can construct the TLT of $\varphi''$ based on that of $\varphi'$, which is shown in Fig. 9 and then continue to implement Algorithm 3. We can see that the vehicle changes lane from $[86.3, -2.5]^T$ and quickly merges back after overtaking $O_2$. Under the control with respect to $\varphi''$, the vehicle finally reaches the target set $T$.

Fig. 9(a) shows the state trajectories, from which we can see that the whole specification is completed. Fig. 9(b)–(c) show the corresponding control inputs, where the dashed lines denote the control bounds. The cyan regions represent the synthesized control sets and the blue lines are the control trajectories. Furthermore, we repeat the above process for 100 realizations of the disturbance trajectories. The state trajectories for such 100 realizations are shown in Fig. 10.

We remark that in this example, the control inputs are chosen to push the state to move down along the TLT as fast as possible. In detail, if the state $x_k$ is the $i$-step reachable set in the set node $R^c(X, T)$, we can generate a smaller control set from which the control input can push the state to the $(i-1)$-step reachable set. That is what we can see from Fig. 9 where almost all control inputs in the synthesized control sets along $x$-axis are positive.

VII. CONCLUSIONS AND FUTURE WORK

We have studied LTL model checking and control synthesis for discrete-time uncertain systems. Quite unlike automaton-based methods, our solutions build on the connection between LTL formulae and TLT structures via reachability analysis. For a transition system and an LTL formula, we have proved that the TLTs provide an underapproximation or overapproximation for the LTL via minimal and maximal reachability analysis, respectively. We have provided sufficient conditions and necessary conditions to the model checking problem. For a controlled transition system and an LTL formula, we have shown that the TLT is an underapproximation for the LTL formula and thereby proposed an online control synthesis algorithm, under which a set of feasible control inputs is generated at each time step. We have proved that this algorithm is recursively feasible. We have also illustrated the effectiveness of the proposed methods through several examples.

Future work includes the extension of TLTs to handle other general specifications (e.g., $\text{CTL}^*$) and a broad experimental evaluation of our approach.

APPENDIX A. PROOF OF THEOREM III.1

The whole proof is divided into two parts: the first part shows how to construct a TLT from the formula $\forall \varphi$ by means of the reachability operators $R^m$ and $R$, while the second part shows that such TLT is an underapproximation for $\varphi$.

Construction: We follow three steps to construct a TLT.

Step 1: rewrite the given LTL in the weak-up to the positive normal form. From [4], each LTL formula has an equivalent LTL formula in the weak-up to the positive normal form, which can be inductively defined as

$$\varphi ::= \text{true} | \text{false} | a | \neg \varphi | \varphi_1 \lor \varphi_2 | \bigcirc \varphi | \varphi_1 U \varphi_2 | \varphi_1 W \varphi_2. \quad (5)$$

Step 2: for each atomic proposition $a \in AP$, construct the TLT with only a single node set from $\forall a$ or $\forall \neg a$. In detail, the set node for $\forall a$ is $L^{-1}(a) = \{ x \in S \mid a \in L(x) \}$ while the set node for $\forall \neg a$ is $S \setminus L^{-1}(a)$. In addition, the TLT for $\forall \text{true}$ (or $\forall \text{false}$) also has a single set node, which is $S$ (or $\emptyset$).

Step 3: based on Step 2, follow the induction rule to construct the TLT for any LTL formula in the weak-up to the positive normal form. More specifically, we will show that given the LTL formulae $\varphi_1$ and $\varphi_2$ in the weak-up to the positive normal form, if the TLTs can be constructed from $\forall \varphi_1$, $\forall \varphi_2$, and $\forall \varphi_1 \lor \varphi_2$ respectively, then the TLTs can be thereby constructed from the formulae $\forall (\varphi_1 \lor \varphi_2)$, $\forall (\varphi_1 \lor \varphi_2)$, $\forall \bigcirc \varphi$, $\forall (\varphi_1 U \varphi_2)$, and $\forall (\varphi_1 W \varphi_2)$ respectively.

For $\forall (\varphi_1 \lor \varphi_2)$ (or $\forall (\varphi_1 \lor \varphi_2)$), we construct the TLT by connecting the root nodes of the TLTs for $\forall \varphi_1$ and $\forall \varphi_2$ through the operator $\lor$ (or $\lor$) and taking the intersection (or union) of two root nodes, as shown in Fig. 11(a)-(b). For $\forall \bigcirc \varphi$, we denote by $X^\varphi$ the root node of the TLT for $\forall \varphi$ and then construct the TLT by adding a new set node $R^m(S, X^\varphi, 1)$ to be the parent of $X^\varphi$ and connecting them through the operator $\bigcirc$, as shown in Fig. 11(c).

For $\forall (\varphi_1 U \varphi_2)$, the TLT construction is as follows. Denote by $\{(Y^\varphi_1, O^\varphi_1)\}_{i=1}^{N^\varphi_1}$ all the pairs comprising a leaf node and its corresponding parent in the TLT of $\forall \varphi_1$, where $N^\varphi_1$ is the number of the leaf nodes. Here, $Y^\varphi_1$ is the $i$th leaf node and $O^\varphi_1$ is its parent. Denote by $X^{\varphi_2}$ the root node of TLT for $\forall \varphi_2$. We first change each leaf node $Y^\varphi_1$ to $R^m(Y^\varphi_1, X^{\varphi_2}) \setminus X^{\varphi_2}$. We then update the new tree for $\forall \varphi_1$ from the leaf node to the root node according to the definition of the operators. After that, we take $N^\varphi_2$ copies of the TLT of $\varphi_2$. We set the root node of each copy as the child of each new leaf node, respectively, and connect them trough the operator $U$. Finally, we have one more copy of the TLT of $\forall \varphi_2$ and connect this copy and the new tree trough the disjunction $\lor$. An illustrative diagram is given in Fig. 11(d).

For the fragment $\forall (\varphi_1 W \varphi_2)$, we first recall that $\varphi_1 W \varphi_2 = \varphi_1 U \varphi_2 \lor \bigcirc \varphi_2$. Let $\varphi' = \varphi_1 U \varphi_2$ and $\varphi'' = \bigcirc \varphi_2$. Denote by $X^{\varphi_1}$ the root node of the TLT for $\forall \varphi_1$. We first construct the TLT of $\forall \varphi'$ as described above. Second, we further construct the TLT of $\forall \varphi''$ with by adding a new node $RZ(X^{\varphi_1})$ as the parent of $X^{\varphi_1}$ and connecting them through $\Box$. Then, we construct the TLT of $\forall (\varphi' \lor \varphi'')$. An illustrative diagram is given in Fig. 11(e).

Underapproximation: First, it is very easy to verify that the constructed TLT above with a single set node $L^{-1}(a)$ (or $S \setminus L^{-1}(a)$ or ) for $\forall a$ (or $\forall \neg a$ or $S$ or $\emptyset$) is an underapproximation for $a \in AP$ (or $\forall a$ or $\exists a$ or $\forall \text{false}$) and the underapproximation relation in these cases is also tight.

Next we also follow the induction rule to show that the constructed TLT from $\forall \varphi$ is an underapproximation for $\varphi$. Consider LTL formulae $\varphi_1$ and $\varphi_2$. We will show that if the constructed TLTs of $\forall \varphi_1$, $\forall \varphi_2$, and $\forall \varphi_1 \lor \varphi_2$ are the underapproximations of $\forall \varphi_1$, $\forall \varphi_2$, and $\forall \varphi_1 \lor \varphi_2$ respectively, then the TLTs constructed above for the formulae $\forall (\varphi_1 \lor \varphi_2)$, $\forall (\varphi_1 \lor \varphi_2)$, $\forall \bigcirc \varphi$, $\forall (\varphi_1 U \varphi_2)$, and $\forall (\varphi_1 W \varphi_2)$ are the underapproximations of $\forall \varphi_1 \lor \varphi_2$, $\forall \varphi_1 \lor \varphi_2$, $\forall \bigcirc \varphi$, $\forall \varphi_1 U \varphi_2$, and $\forall \varphi_1 W \varphi_2$, respectively.

According to the set operation (intersection or union) or the definition of one-step minimal reachable set, it is easy to verify that the constructed TLT for $\forall (\varphi_1 \lor \varphi_2)$ (or $\forall (\varphi_1 \lor \varphi_2)$) is an underapproximation for $\forall \varphi_1 \lor \varphi_2$ (or $\forall \varphi_1 \lor \varphi_2$) or $\forall \varphi$ if the TLTs of $\forall \varphi_1$ and $\forall \varphi_2$ and $\forall \varphi$ are underapproximations of $\forall \varphi_1$ and $\forall \varphi_2$ respectively.

Let us consider $\varphi_1 U \varphi_2$. Assume that a trajectory $p$ satisfies the TLT of $\forall (\varphi_1 U \varphi_2)$. Recall the construction of the TLT of $\forall (\varphi_1 U \varphi_2)$ from $\forall \varphi_1$ and $\forall \varphi_2$. According to the definition of minimal reachable set, we have (1) $p$ satisfies the TLT of $\forall \varphi_2$ and (2) there exists that $j \in N$ such that $p(j \ldots)$ satisfies the TLT of $\forall \varphi_2$ and for all $i \in N_{[0,j-1]}$, the trajectory $p[i \ldots]$ satisfies the the TLT of $\forall \varphi_1$. Under the assumption that the TLTs of $\forall \varphi_1$ and $\forall \varphi_2$ are the underapproximations of $\forall \varphi_1$ and $\forall \varphi_2$, respectively, we have that there exists $j \in N$ such that $p(j \ldots) \models \varphi_2$ and for all $i \in N_{[0,j-1]}$, $p[i \ldots] \models \varphi_1$, which implies that $p \models \varphi_1 U \varphi_2$. Thus, the TLT of $\forall (\varphi_1 U \varphi_2)$ is an approximation of $\varphi_1 U \varphi_2$.

Recall that $\varphi_1 W \varphi_2 = \varphi_1 U \varphi_2 \lor \bigcirc \varphi_2$. Following the proofs so far, the disjunction $\lor$ and the definition of the robust invariant set, it yields that the constructed TLT of $\forall (\varphi_1 W \varphi_2)$ is an underapproximation of $\varphi_1 W \varphi_2$.

The proof is complete.
