ABSTRACT

The PO\textsubscript{4}\textsuperscript{3−} widespread in urban sewages promotes eutrophication of water sources, with harmful effects to natural life and endanger human health. The removal of PO\textsubscript{4}\textsuperscript{3−} from urban sewage requires treatment at tertiary level, with high costs and low efficiency in most cases. Thus, a functionalization method for surface modification of kaolinite was proposed to improve the removal of PO\textsubscript{4}\textsuperscript{3−} from urban sewage. The kaolinite commercial did not remove PO\textsubscript{4}\textsuperscript{3−} from aqueous solution. However, the functionalized kaolinite (FK) was efficient, with a maximum removal capacity of 8.4 ± 0.1 mg PO\textsubscript{4}\textsuperscript{3−}/L, within less than 1 min of reaction. The removal of PO\textsubscript{4}\textsuperscript{3−} is associated with precipitation of pyromorphite, a mineral with low solubility (K\textsubscript{sp} < 10\textsuperscript{-79.0}). Finally, real urban sewage samples (raw and treated) were also tested for removal of PO\textsubscript{4}\textsuperscript{3−} using FK, confirming its effectiveness. The central aspects of this development are:

- Functionalized kaolinite (FK), with Pb(II), for removal of PO\textsubscript{4}\textsuperscript{3−} from urban sewage was studied.
- The FK was efficient for removal of up to 8.4 mg PO\textsubscript{4}\textsuperscript{3−}/L from aqueous solution, within a short reaction time.
- The precipitation of pyromorphite was the mechanism responsible for removal of PO\textsubscript{4}\textsuperscript{3−} and FK efficiency have been confirmed for real urban sewage samples.

Method details

Background

The PO₄³⁻ present in urban sewage promotes eutrophication in the water bodies [1]. This anion is difficult to remove during the treatment of urban sewage, requiring treatment at the tertiary level [2]. The most used method for the removal of PO₄³⁻ from urban sewage is the chemical precipitation, involving the addition of bivalent or trivalent metal salts [3–5]. Recently, studies have shown the precipitation of pyromorphite (5Pb²⁺ + 3PO₄³⁻ + H₂O → Pb₅(PO₄)₃(OH)(pyromorphite) + H⁺) in natural surface waters due to presence of PO₄³⁻ and Pb(II), reducing the concentration of dissolved Pb(II) [6,7]. The pyromorphite has a low solubility constant (Ksp < 10⁻⁷⁹.6), preventing that the Pb(II) returns to the environment as a dissolved cation [8–10].

Kaolinite [Al₂Si₂O₅(OH)₄] has its negatively-charged surface, becoming this mineral an important adsorbent for cationic ions [11]. The functionalization of kaolinite with acid treatment [12] and bivalent trace elements can promote the removal of anionic molecules, such as PO₄³⁻, present in the urban sewage [13–15]. Based on the functionalization of commercial kaolinite (CK) with bivalent trace elements, the functionalized kaolinite (FK) with Pb(II) was produced. The efficiency for removal of PO₄³⁻ from aqueous solution using FK was studied and compared with CK. Furthermore, the reaction time and maximum removal capacity of PO₄³⁻ was determined using FK. Finally, the FK was applied in real urban sewage samples, attesting its effectiveness.

Functionalization of commercial kaolinite

The CK (Sigma-Aldrich®, CAS Number 1318-74-7) was used in this study. The following procedures have been applied for the functionalization:

1 – About 1.0 g of CK was placed in a beaker;
2 – 10 mL of aqueous solution with Pb(II) initial concentration of 40 mg/L was added;
3 – The beaker was agitated (digital shaker Biohec – model BT 645) for 24 h at 145 rpm;
4 – The solution was centrifuged (centrifuge Excelsa II® – model 206-BL) for 25 min at 3000 rpm;
5 – The FK was separated and washed three times, using ultrapure water (Milli-Q® system - model IQ 7000) with electrical conductivity lower than 0.02 μS/cm;
6 – Finally, the FK was dried for 12 h at 40 °C.

Method validation

For validation purposes, 1.0 g of each sample (CK and FK) was mixed with 10 mL of aqueous solution containing PO₄³⁻ in the initial concentration (C₀) of 1 mg/L at pH 6 [9]. The suspension was shaken for 24 h at 145 rpm, and then centrifuged at 3000 rpm for 25 min. The supernatant was separated and the PO₄³⁻ concentration remaining in solution (Cₑ) was measured using a Hach DR-2800 spectrophotometer, with a detection limit of 0.1 mg/L. The removal efficiency of PO₄³⁻ (%A – in percentage) was determined according to the Eq. 1. The experimental procedures were carried out in triplicate.

\[ \%A = \left( \frac{C₀ - Cₑ}{C₀} \right) \times 100 \] (1)
Table 1
Removal efficiency (%A) of PO₄³⁻ (mg/L) using FK and CK in aqueous solution.

|     | CK       |   | FK         |          |
|-----|----------|---|------------|----------|
| C₀  | Cₑ       | %A| C₀         | Cₑ       |
| 1.0 | 1.0 ± 0.1 | 0 | 1.0        | < 0.1    |

Table 2
Reaction time (min) and removal efficiency (%A) of PO₄³⁻ (mg/L) using FK in aqueous solution.

| Time | C₀    | Cₑ     | %A  |
|------|-------|--------|-----|
| 0    | 1.0   | 1.0 ± 0.1 | 0   |
| 1    | 1.0   | < 0.1   | 100 |
| 5    | 1.0   | < 0.1   | 100 |
| 15   | 1.0   | < 0.1   | 100 |
| 30   | 1.0   | < 0.1   | 100 |
| 60   | 1.0   | < 0.1   | 100 |

Table 3
Maximum removal capacity of PO₄³⁻ using FK and concentration of residual Pb(II) in aqueous solution.

| PO₄³⁻ (mg/L) | Pb(II) (mg/L) |
|--------------|---------------|
| C₀           | Cₑ            | %A     |
|              |               | 692 ± 20 |
| 1            | < 0.1         | 100    |
| 2            | < 0.1         | 100    |
| 3            | < 0.1         | 63 ± 3 |
| 4            | < 0.1         | 100    |
| 7            | < 0.1         | 100    |
| 9            | 0.6 ± 0.1     | 93.3   |

The results are presented in Table 1. The removal efficiencies of PO₄³⁻ were 0 and 100% using CK and FK, respectively. These results evidenced the functionalization plays a crucial role on the removal of PO₄³⁻. The precipitation of pyromorphite was the main mechanism associated with PO₄³⁻ removal using FK with Pb(II), as shown in Fig. 1.

Reaction time and maximum removal capacity of PO₄³⁻ using functionalized kaolinite

The reaction time for removal of PO₄³⁻ using KF has been investigated, according the following procedures carried out in triplicate. The FK (1.0 g) was mixed in 10 mL of an aqueous solution with C₀ of 1 mg PO₄³⁻/L at pH 6 [9]. The suspension was shaken at 145 rpm, with samples taken after 1, 5, 15, 30 and 60 min. The solution was centrifuged at 3000 rpm for 25 min, with the supernatant separated and the Cₑ determined. The experiments have shown no residuals of PO₄³⁻ after 1 min of reaction time (Table 2), showing a fast reaction time for removal of PO₄³⁻ associated to the mineral pyromorphite precipitation.

The maximum removal capacity of PO₄³⁻ using FK was also determined (in triplicate). The samples with 1.0 g: 10 mL of an aqueous solution with C₀ of 1 mg/L were stirred at 145 rpm for 5 min at pH 6 [9], with C₀ of 1, 2, 3, 4, 7 and 9 mg/L. The solutions were centrifuged for 25 min at 3000 rpm and the Cₑ determined in the supernatants. The maximum removal capacity of PO₄³⁻ using FK was 8.4 ± 0.1 mg/L (Table 3) or 8.4 mg/g, indicating an efficiency of 93.3% for removal of PO₄³⁻ from aqueous solutions with C₀ of 9 mg/L. The value of 8.4 mg/g is higher than the removal capacities obtained for natural or functionalized kaolinite, i.e., CK used in this study (< 0.1 mg/g), kaolinite from Linthipe (ca. 0.15 mg/g) [12], modified kaolinite with FeCl₃ (1.31 mg/g) [13] and modified kaolinite with seawater in different temperatures (4.07 mg/g at 600 °C) [15].

Trace levels of residual Pb(II) in the treated effluent can pose a serious environmental risk for aquatic systems due to its toxicity. Thus, the concentration of Pb(II) were also determined in the
Fig. 1. SEM-EDS images of functionalized kaolinite after the removal of PO$_4^{3-}$, showing the precipitation of small grains (lower than 5 μm) of pyromorphite (spots 1, 2 and 3).
supernatants by inductively coupled plasma optical emission spectrometry (ICP OES), iCAP 6000 SERIES machine Thermo Scientific, with detection limit of 0.006 mg/L. The presence of residual Pb(II) in aqueous solutions was measured in aqueous solutions with $C_0$ of 1, 2 e 3 mg/L of $\text{PO}_4^{3-}$. Residual Pb(II) was not detected for $C_0$ of $\text{PO}_4^{3-} \geq 4$ mg/L, indicating the use of FK for removal of $\text{PO}_4^{3-}$ only in urban sewage with $C_0 \geq 4$ mg/L. Further studies for lower $C_0$ concentrations in urban sewage are encouraged before application.

### Removal of $\text{PO}_4^{3-}$ using functionalized kaolinite in real urban sewage samples

Three samples of raw and treated urban sewage were collected in a wastewater treatment plant (WWTP) located in Rio Claro, São Paulo State, Brazil. These samples were stored in labeled amber container at 4°C and transported immediately to the laboratory, where they were filtered, using 0.45 μm MF-Millipore® membrane filter, and the $C_0$ of $\text{PO}_4^{3-}$ and Pb(II) measured (Table 4). In order to verify the real removal efficiency of $\text{PO}_4^{3-}$ from urban sewage (raw and treated), 10 mL of each filtered sample were mixed with 1.0 g of FK. The solutions were shaken at 145 rpm for 5 min at pH 6 [9], centrifuged at 3000 rpm for 25 min, and then the $C_e$ of $\text{PO}_4^{3-}$ and Pb(II) were determined in the supernatants (Table 4).

The $C_0$ averages of $\text{PO}_4^{3-}$ were 6.1 ± 0.1 e 3.8 ± 0.1 mg/L, respectively, for raw and treated urban sewage. After the use of FK, $C_e$ averages of $\text{PO}_4^{3-}$ were lower than 0.1 mg/L. In addition, the $C_0$ and $C_e$ averages of Pb(II) were always lower than the detection limit of 0.006 mg/L. These results show the efficiency during the use of FK for removal of $\text{PO}_4^{3-}$ from urban sewage in real samples collected in a WWTP.

### Conclusions

A method for functionalization of kaolinite for removal of $\text{PO}_4^{3-}$ from urban sewage was studied. The functionalized kaolinite (FK) with Pb(II) have shown a promising alternative for removal of $\text{PO}_4^{3-}$ in aqueous solution, with maximum removal capacity of 8.4 mg/L, within a reaction time lower than 1 min. The precipitation of $\text{PO}_4^{3-}$ is associated with pyromorphite, a mineral with low solubility ($K_{sp} < 10^{-79.6}$). Finally, real urban sewage samples (raw and treated) were also tested for removal of $\text{PO}_4^{3-}$ using KF, confirming its effectiveness for removal of $\text{PO}_4^{3-}$ from urban sewage with $C_0 \geq 4$ mg/L.
