Introduc ion

Morel-Lavallée lesions (MLL) are uncommon shearing injuries resulting in separation of the skin and subcutaneous tissue from the underlying fascia - closed internal degloving injuries, classically occurring around the greater trochanter (30.4%), pelvis (18.6%), thigh (20.1%), knee joint (15.7%), gluteal region (6.4%), lumbosacral area (3.4%), abdominal area (1.4%), lower leg (1.5%) and on the head (0.5%) [1], but can appear elsewhere as well [2].

MLL typically occur in the setting of high-speed motor vehicle accident and direct crush to the area [3,4]. Shearing forces cause bone, muscle and deep fascia shear one way and superficial layers such as the superficial fascia, subcutaneous fat and skin, shear the opposite direction, causing perforating arteries and lymphatic vessels to tear [3].

The detachment of the tissues creates a unique potential space that is filled with hemolymphatic and serotic fluid, blood, necrotic fat and lymphatic tissue, leading to cavity formation. Metabolic and inflammatory products within the fluid then potentiate cellular permeability and further exacerbate leakage into the space created. Later granular tissue forms in the periphery of the cavity and may result in fibrinous pseudo capsule formation [5]. The pseudo capsule, in turn, prevents resorption thus causing chronic fluid accumulation with high risk for infection of tissue necrosis. Since the mechanism of injury is often traumatic, bacterial infection is a concern especially when an open lesion of the skin is also present [6]. The collection of blood products and necrotic material occurs within the space created in the lesion potentially result in abscesses, cellulitis or osteomyelitis [5,7].

This work has been reported in line with the SCARE criteria [8].

Case report

A 59-years-old male, with no prior medical history, was injured in his right thigh as a result of a crushing injury during his work as a fisherman. The thigh was crushed between his ship and a rope for 15 min. The patient was transported to a nearby hospital. Fracture was ruled out and the patient was transferred to our hospital, since his home is closer to our center.

In the emergency department (ED), an abrasion was noted (Fig. 1). Vascular investigation showed patent vessels. X-ray imaging showed no fracture. In computed tomography (CT) there was a significant sub-dermal edema, with fat opacity. The patient was hospitalized for 5 days. Upon his discharge (Fig. 2), a dry superficial necrotic skin area was noted, with no fluctuation or infection.

One week after discharge, during a routine follow-up, the patient mentioned a fever 2 days prior to the follow-up. He was treated with Augmentin (amoxicillin-clavulanic acid) 875 mg BD. In his exam, there was mild cellulitis noted.

One week later, during the second follow-up, a 3rd year resident physician from our department was called to consult. An area of skin necrosis, roughly 10 × 15 cm, was noted. The was a significant swelling and fluctuation (Fig. 3).

The patient rushed to ED, where drainage took place. Approximately 3 L of blood, necrotic muscles and skin were drained. The patient was hospitalized in our department.
During the day of arrival, laboratory findings showed leukocytosis of 21 K, with CRP of 15. The patient underwent CT, which showed hamstring necrosis and a new subdermal collection in the right perineum, continues with the collection in the right thigh. The patient was taken to the operating room (OR).
In the OR, the patient underwent extensive debridement of the hamstring’s region to the deep fascia. The patient was dressed with vacuum assisted closure (VAC) dressing. Culture swabs taken and an empiric treatment of Rocephin and Clindamycin initiated. Fig. 4 presents the patient before, during and after surgery.

Due to cultures showing S. aureus and P. aeruginosa the treatment was changed to Ciprofloxacin and Cefazoline.

The patient underwent 2 split thickness skin grafts. The first graft failed due to a different P. aeruginosa found in the wound bed. The second graft succeeded and the patient was discharged to his home.
During follow-up in the outpatient clinic, the patient was dressed with Aquacel® AG (Convatec, Oklahoma City, OK, USA) bandage until fully healed. Signs of hypertrophic scar were noted, and the patient was referred to physical therapist for silicone dressing.

3. Review of literature

3.1. Diagnosis

MLL are often delayed or misdiagnosed due to delayed presentation or the presence of distracting injuries, such as in the incidence of multi-trauma. Diagnosis of MLL is mainly a clinical diagnosis and should be taken into account in every traumatic setting. Suspicion should arise in the case of localized swelling, especially with fluctuation. After clinical suspicion imaging studies should be performed. Magnetic resonance imaging (MRI) is the modality of choice since it allows for excellent soft tissue evaluation and high contrast resolution. Ultrasound (US) can be done as first step and usually demonstrates the lesion as an anechoic area. Doppler US can be used to rule out other diagnoses and suspicion of vascular compromise such as deep vein thrombosis (DVT) [5,9–12]. CT is not recommended but can demonstrate fluid accumulation. It should be noted that in cases of late diagnosis and imaging, imaging studies might mislead and be interpreted as soft tissue mass or neoplasm. MLL are considered chronic lesion when the lesion contains a capsule [13].

3.2. Treatment

Treatment options range from conservatively to surgically. Non-surgical management has been recommended if the lesions are
A- After drainage in emergency department; B,C – During operation, before debridement; D – During operation, after debridement; E – VAC dressing

Fig. 4. After drainage, during and post operation. A – After drainage in emergency department; B,C – During operation, before debridement; D – During operation, after debridement; E – VAC dressing.

Another option is the use of liposuction. That was demonstrated in treatment of a 33-years old woman who presented with a large MLL in her left thigh, 3 weeks after involvement in a motor vehicle accident. Fluid collection was confirmed by x-ray and CT. Liposuction of the cavity and seroma wall was performed and a temporary drain, oral antibiotics and thigh compression were administered post-operatively. No fluid collection was evident in a 1- and 6-weeks follow-up examinations [17].

The use of sclerosing agents was described as a method to close potential space and cavity formed in the lesion. Sclerosing agents cause cell destruction within the periphery of the lesion and induces fibrosis. Doxycycline has shown efficacy in lesions up to 700 mL in volume, with the mean volume of treated lesions being approximately 400 mL [18]. The use of talc to treat chronic MLL was described in 4 patients - all presented with lesion in the thigh or buttock area that persisted for more than 3 months. Talc was administered under fluoroscopic guidance and suction drainage was applied for 12 days. All persistent pseudocysts showed an immediate cessation of fluid accumulation in the treated space without recurrence [19]. Other agents such as bleomycin, tetracycline and erythromycin have been utilized but are not considered ideal agents [20].

There are no mentions in current literature of specific indications for skin grafting or flap transplantation as specific treatment for MLL. It is therefore should be considered in cases of open wound.

4. Conclusion

MLL is an uncommon entity, which can result in a life or organ threatening situation. It is important for the caregivers, in ED and community clinics, to be aware of this entity, it’s complications and treatment options.

Declaration of Competing Interest

All authors state no conflict of interest.
Funding

No funding was received for this research.

Ethical approval

This study is exempt from ethical approval.

Consent

Written informed consent was obtained from the patient for publication of this case report and accompanying images. A copy of the written consent is available for review by the Editor-in-Chief of this journal on request.

Author's contribution

Pikkel YY – writing the paper.
Hasan MJ – Treatment of patient, supplying figures.
Ben-Yehuda Raz D – writing the paper.
Ben-Naftaly Y – Treatment of patient.
Duek OS – Treatment of patient.
