NONSMOOTHABLE, LOCALLY INDICABLE GROUP ACTIONS ON THE INTERVAL

DANNY CALEGARI

Abstract. By the Thurston stability theorem, a group of $C^1$ orientation-preserving diffeomorphisms of the closed unit interval is locally indicable. We show that the local order structure of orbits gives a stronger criterion for nonsmoothability that can be used to produce new examples of locally indicable groups of homeomorphisms of the interval that are not conjugate to groups of $C^1$ diffeomorphisms.

1. Introduction

1.1. Acknowledgment. This note was inspired by a comment in a lecture by Andrés Navas. I would like to thank Andrés for his encouragement to write it up. I would also like to thank the referee, whose many excellent comments have been incorporated into this paper.

2. Nonsmoothable actions

2.1. Thurston stability theorem. A simple, but important case of the Thurston Stability Theorem is usually stated in the following way:

Theorem 2.1 (Thurston Stability Theorem [8]). Let $G$ be a group of orientation-preserving $C^1$ diffeomorphisms of the closed interval $I$. Then $G$ is locally indicable; i.e. every nontrivial finitely generated subgroup $H$ of $G$ admits a surjective homomorphism to $\mathbb{Z}$.

The proof is non-constructive, and uses the axiom of choice. The idea is to “blow up” the action of $H$ near one of the endpoints at a sequence of points that are moved a definite distance, but not too far. Some subsequence of blow-ups converges to an action by translations.

Note that it is only finitely generated subgroups that admit surjective homomorphisms to $\mathbb{Z}$, as the following example of Sergeraert shows.

Example 2.2 (Sergeraert [7]). Let $G$ be the group of $C^\infty$ orientation-preserving diffeomorphisms of $I$ that are infinitely tangent to the identity at the endpoints. Then $G$ is perfect.

Another countable example comes from Thompson’s group.

Example 2.3 (Navas [6], Ghys-Sergiescu [3]). Thompson’s group $F$ of dyadic rational piecewise linear homeomorphisms of $I$ is known to be conjugate to a group of $C^\infty$ diffeomorphisms. On the other hand, the commutator subgroup $[F, F]$ is simple; since it is non-Abelian, it is perfect.

Date: 2/19/2008, Version 0.04.
Given a group $G \subset \text{Homeo}_+(I)$, Theorem [2.1] gives a criterion to show that the action of $G$ is not conjugate into $\text{Diff}^1_+(I)$. It is natural to ask whether Thurston’s criterion is sharp. That is, suppose $G$ is locally indicable. Is it true that every homomorphism from $G$ into $\text{Homeo}_+(I)$ is conjugate into $\text{Diff}^1_+(I)$? It turns out that the answer to this question is no. However, apart from Thurston’s criterion, very few obstructions to conjugating a subgroup of $\text{Homeo}_+(I)$ into $\text{Diff}^1_+(I)$ are known. Most significant are dynamical obstructions concerning the existence of elements with hyperbolic fixed points when the action has positive topological entropy [4], or when there is no invariant probability measure [2] (also, see [1]).

In this note we give some new examples of actions of locally indicable groups on $I$ that are not conjugate to $C^1$ actions.

Example 2.4 ($\mathbb{Z}^2$). Let $T : I \to I$ act freely on the interior, so that $T$ is conjugate to a translation. Let $I_0 \subset \text{int}(I)$ be a closed fundamental domain for $T$, and let $S : I_0 \to I_0$ act freely on the interior. Extend $S$ by the identity outside $I_0$ to an element of $\text{Homeo}_+(I)$. For each $i \in \mathbb{Z}$ let $I_i = T^i(I_0)$ and let $S_i : I_i \to I_i$ be the conjugate $T^i S T^{-i}$. For each $f \in \mathbb{Z}^2$ define $Z_f$ to be the product

$$Z_f = \prod_{i \in \mathbb{Z}} S_i^{f(i)}$$

Let $G$ be the group consisting of all elements of the form $Z_f$. Then $G$ is isomorphic to $\mathbb{Z}^2$ and is therefore abelian.

However, $G$ is not conjugate into $\text{Diff}^1_+(I)$. For, suppose otherwise, so that there is some homeomorphism $\varphi : I \to I$ so that the conjugate $G^\varphi \subset \text{Diff}^1_+(I)$. We suppose by abuse of notation that $S_i$ denotes the conjugate $S_i^\varphi$. For each $i$, let $p_i$ be the midpoint of $I_i$. Since for each fixed $i$ the sequence $S_i^n(p_i)$ converges to an endpoint of $I_i$, as $n$ goes to infinity, it follows that for each $i$ there is some $n_i$ so that $dS_i^{n_i}(p_i) < 1/2$. Let $F \in \mathbb{Z}^2$ satisfy $F(i) = n_i$. Then $dZ_F(p_i) < 1/2$ for all $i$. However, $Z_F$ fixes the endpoints of $I_i$ for all $i$, so $Z_F$ has a sequence of fixed points converging to 1. It follows that $dZ_F(1) = 1$. But $p_i \to 1$, so if $Z_F$ is $C^1$ we must have $dZ_F(1) \leq 1/2$. This contradiction shows that no such conjugacy exists.

Remark 2.5. The group $\mathbb{Z}^2$ is locally indicable, but uncountable. Note in fact that this group action is not even conjugate to a bi-Lipschitz action. On the other hand, Theorem D from [2] says that every countable group of homeomorphisms of the circle or interval is conjugate to a group of bi-Lipschitz homeomorphisms.

2.2. Order structure of orbits. In this section we describe a new criterion for non-smoothability, depending on the local order structure of orbits.

Definition 2.6. Let $G$ act on $I$ by $\rho : G \to \text{Homeo}_+(I)$. A point $p \in I$ determines an order $<_p$ on $G$ by

$$a <_p b$$

if and only if $a(p) < b(p)$ in $I$.

Note that with this definition, $<_p$ is really an order on the left $G$-space $G/G_p$, where $G_p$ denotes the stabilizer of $p$.

Lemma 2.7. Suppose $\rho : G \to \text{Diff}^1_+(I)$ is injective. Let $H$ be a finitely generated subgroup of $G$, with generators $S = \{h_1, \ldots, h_n\}$. Let $p \in I$ be in the frontier of $\text{fix}(H)$ (i.e. the set of common fixed points of all elements of $H$) and let $p_i \to p$ be a sequence contained in $I - \text{fix}(H)$. Then there is a sequence $k_m \in \{1, \ldots, n\}$ and
\( e_m \in \pm 1 \) such that for any \( h \in [H, H] \), and for all sufficiently large \( m \) (depending on \( h \)), there is an inequality
\[
h < p_m h_{k_m}^{e_m}
\]

**Proof.** There is a homomorphism \( \rho : H \to \mathbb{R} \) defined by the formula \( \rho(h) = \log h' (p) \). Of course this homomorphism vanishes on \([H, H]\). If \( h_i \) is such that \( \rho(h_i) \neq 0 \) then (after replacing \( h_i \) by \( h_i^{-1} \) if necessary) it is clear that for any \( h \in [H, H] \), there is an inequality \( h < p_m h_i \) for all \( p_m \) sufficiently close to \( p \). Therefore in the sequel we assume \( \rho \) is trivial.

For each \( i \), let \( U_i \) be the smallest (closed) interval containing \( p_i \cup S p_i \). Given a bigger open interval \( V_i \) containing \( U_i \), one can rescale \( V_i \) linearly by \( 1/\text{length}(U_i) \) and move \( p_i \) to the origin thereby obtaining an interval \( V_i \) on which \( H \) has a partially defined action as a pseudogroup.

The argument of the Thurston stability theorem implies that one can choose a sequence \( V_i \) such that any sequence of indices \( \to \infty \) contains a subsequence for which \( V_i \to \mathbb{R} \), and the pseudogroup actions converge, in the compact-open topology, to a (nontrivial) action of \( H \) on \( \mathbb{R} \) by translations. In an action by translations, some generator or its inverse moves 0 a positive distance, but every element of \([H, H]\) acts trivially. The proof follows. \( \square \)

**Example 2.8.** Let \( T \) be a hyperbolic once-punctured torus with a cusp. The hyperbolic structure determines up to conjugacy a faithful homomorphism \( \rho : \pi_1(T) \to \text{PSL}(2, \mathbb{R}) \).

The group \( \text{PSL}(2, \mathbb{R}) \) acts by real analytic homeomorphisms on \( \mathbb{R}P^1 = S^1 \). Since \( \pi_1(T) \) is free on two generators (say \( a, b \)) the homomorphism \( \rho \) lifts to an action \( \tilde{\rho} \) on the universal cover \( \mathbb{R} \). We choose a lift so that both \( a \) and \( b \) have fixed points. If we choose co-ordinates on \( \mathbb{R} \) so that \( a \) fixes \( x \), then \( a \) also fixes \( x + n \) for every integer \( n \). Similarly, if \( b \) fixes \( y \), then \( b \) fixes \( y + n \) for every \( n \). On the other hand, if \( p \in S^1 \) is the parabolic fixed point of \([a, b] \), and \( \tilde{p} \) is a lift of \( p \) to \( \mathbb{R} \), then the commutator \([a, b] \) takes \( \tilde{p} \) to \( \tilde{p} + 1 \). Since the action of every element on \( \mathbb{R} \) commutes with the generator of the deck group \( x \to x + 1 \), the element \([a, b] \) acts on \( \mathbb{R} \) without fixed points, and moves every point in the positive direction, satisfying \([a, b]^n(z) > z + n - 1 \) for every \( z \in \mathbb{R} \) and every positive integer \( n \). See Figure 1.

![Figure 1](image-url)

**Figure 1.** In the lifted action, \( a \) and \( b \) have fixed points, but \([a, b] \) takes \( \tilde{p} \) to \( \tilde{p} + 1 \).
This action on $\mathbb{R}$ can be made into an action on $I$ by homeomorphisms, by including $\mathbb{R}$ in $I$ as the interior. Then the points $\hat{p} + n \rightarrow \infty$ in $\mathbb{R}$ map to points $p_n \rightarrow 1$ in $I$. Note that for each $n$, the elements $a$ and $b$ have fixed points $q_n, r_n$ respectively satisfying $p_n < q_n < p_{n+1}$ and $p_n < r_n < p_{n+1}$. Moreover, $[a, b](p_n) = p_{n+1}$ for all $n$. It follows that

$$a, a^{-1} < p_n [a, b]^2, \quad b, b^{-1} < p_n [a, b]^2$$

for every $n$, so by Lemma 2.7 this action is not topologically conjugate into $\text{Diff}_+^1(I)$. On the other hand, this is a faithful action of the free group on two generators. A free group is locally indicable, since every subgroup of a free group is free.

Remark 2.9. The relationship between order structures and dynamics of subgroups of homeomorphisms of the interval is subtle and deep. For an introduction to this subject, see e.g. [5].
