\textbf{Abstract}

A class of Kolmogorov differential system is introduced. It is shown that under suitable assumptions on degrees and parameters, algebraic limit cycles can occur. We propose an easy algorithm to test the existence of limit cycles and we give them explicit expressions.

\textbf{1. Introduction}

The second part of sixteenth problem of Hilbert raises the question of the maximum number and the mutual position of limit cycles of the differential system:

\begin{equation}
\begin{aligned}
\dot{x} &= \frac{dx}{dt} = P(x,y) \\
\dot{y} &= \frac{dy}{dt} = Q(x,y)
\end{aligned}
\end{equation}

where $P$ and $Q$ are two polynomials of any degree.

Many mathematical models in population dynamics, frequently involve the systems of ordinary differential equations having the form

\begin{equation}
\begin{aligned}
\dot{x} &= \frac{dx}{dt} = xF(x,y) \\
\dot{y} &= \frac{dy}{dt} = yG(x,y),
\end{aligned}
\end{equation}

$x(t)$ and $y(t)$ represent the population density of two species at time $t$, and $F(x,y)$, $G(x,y)$ are the capita growth rate of each specie, usually, such systems are called Kolmogorov systems.

Kolmogorov models are widely used in ecology to describe the interaction between two populations, and a limit cycle corresponds to an equilibrium state of the system.

In mathematical modeling of ecological systems and population dynamics, more mathematicians and scientists were attracted to the subject and several results have been published, May[15], Kuang and Freedman[12], X. Huang, Y. Wang, A. Cheng [11], and others.

When $F(x,y)$ and $G(x,y)$ are polynomials of degrees $\geq 2$, limit cycles can occur and there is an extensive literature dealing with their existence, number and stability (see for instance Lloyd, Pearson, Sáez and Szántó[13], X.C. Huang, L. Zhu [9], X.C. Huang[10], S.Boqian and L.Demeng [5], K.S. Cheng [6],...), but to our knowledge, the exact analytic expressions of the limit cycles for a given kolmogorov system is still unknown except for simple and specific cases. This paper is a contribution in this direction, to determine the number of limit cycles and to give their explicit form.

Motivated by the recent publication of some research papers exhibiting planar polynomial systems with one or more algebraic limit cycles analytically given (see for instance A. Bendjeddou and R. Cheurfa[1], [2], S.Benyousef, A. Barbach and A.Bendjeddou, [3], S. Benyoucef

\textbf{Keywords:} Kolmogorov differential system, Invariant curve, Periodic solution, Hyperbolic limit cycle

\textbf{2010 AMS:} 34C25, 34A34, 34C05

\textbf{Received:} 18 May 2018
\textbf{Accepted:} 16 September 2018
\textbf{Available online:} 30 September 2018
and A. Bendjeddou [4], S. Chengbin, S. Boqian [7], Lloyd, Pearson, Sáez and Szántó [14], Peng Yue-hui [17]), we will study the existence and the number of limit cycles of a class of Kolmogorov system, and give their explicit form.

Mainly based on the work of Article [4], we will enter some disruption on the differential system, adding other terms and changing the parameters.

2. Some useful notions

Let recall some useful notions.

For \( U \in \mathbb{R}[x,y] \), the algebraic curve \( U = 0 \) is called an invariant curve of the polynomial system (1.2), if for some polynomial \( K \in \mathbb{R}[x,y] \) called the cofactor of the algebraic curve, we have

\[
xF(x,y) \frac{\partial U}{\partial x} + yG(x,y) \frac{\partial U}{\partial y} = KU
\]

(2.1)

The curve \( \Gamma = \{(x,y) \in \mathbb{R}^2 : U(x,y) = 0\} \) is nonsingular of system (1.2) if it is without singular points. The singular points or the equilibrium points of system (1.2) satisfy

\[
\begin{align*}
xF(x,y) &= 0 \\
yG(x,y) &= 0
\end{align*}
\]

(2.2)

If the curve \( \Gamma \) is nonsingular of system (1.2), the equilibrium points of the system are contained either in its unbounded components or are located on the curve \( K = 0 \).

A limit cycle \( \gamma = \{(x(t),y(t)) : t \in [0,T]\} \), is a \( T \)–periodic solution isolated with respect to all other possible periodic solutions of the system.

The \( T \)–periodic solution \( \gamma \) is an hyperbolic limit cycle if \( \int_0^T \text{div}(\gamma(t))dt \) is different from zero [16].

We construct here a multi-parameter planar differential system admitting the components of curve

\[
\Gamma = \{(x,y) \in \mathbb{R}^2 : x^{2n} + bx^n + cy^{2m} + \gamma^m(d + fx^n) + h = 0, \ (n,m) \in \mathbb{N}^* \times \mathbb{N}^*\}
\]

(2.3)

as hyperbolic limit cycles if some conditions on the parameters are satisfied.

Note that our study is not restricted to the realistic quadrant \( \{(x,y) \in \mathbb{R}^2 : x > 0, y > 0\} \), but it covers all the domain \( \mathbb{R}^2 \).

3. The main result

As a main result, we have the following theorem

**Theorem 3.1.** The system

\[
\begin{align*}
\dot{x} &= x \left( yP(x) + V(y) \right) \left( ax^{2n} + bx^n + cy^{2m} + dy^m + fx^n y^m + h \right) - my^m \left( d + 2cy^m + fx^n \right) \\
\dot{y} &= y \left( xQ(y) + W(x) \right) \left( ax^{2n} + bx^n + cy^{2m} + dy^m + fx^n y^m + h \right) + nx^n \left( b + 2ax^n + fy^m \right)
\end{align*}
\]

(3.1)

where \( a,c \) are positive real, \( b,d \) are negative real, \( f \) is negative real such as \( f^2 < 4ac \), \( h \) satisfied

\[
\max \left\{ \frac{b^2}{4d}, \frac{d^2}{4c} \right\} < h < \frac{bd f - b^2 c - ad^2}{f^2 - 4ac}, \ (n, m) \in \mathbb{N}^* \times \mathbb{N}^*
\]

(3.2)

\( P(x) \) and \( Q(y) \) are odd polynomial functions of any degree with positive coefficients, \( V(x) \) and \( W(y) \) are analytic functions.

This system admits

One limit cycle when \( n \) and \( m \) are odd numbers.

Two limit cycles when \( n \) is even and \( m \) is odd and the other is even.

Four limit cycles when \( n \) and \( m \) are even numbers.

The limit cycles are hyperbolic represented by the curve \( \Gamma \).

**Proof.** We will prove that \( \Gamma \) is nonsingular composed of ovals and it is an invariant curve of system (3.1), and \( \int_0^T \text{div}(\Gamma)dt \neq 0 \). (see for instance Perko [16])

i) The curve \( \Gamma \) is non singular of system composed of ovals.

We recall that the curve \( \Gamma \) is non-singular of system (3.1) if the following system has no real solution.

\[
\begin{align*}
a x^{2n} + bx^n + cy^{2m} + dy^m + fx^n y^m + h &= 0 \\
nx^n \left( b + 2ax^n + fy^m \right) &= 0 \\
-my^m \left( d + 2cy^m + fx^n \right) &= 0
\end{align*}
\]

(3.3)

Note that the curve \( \Gamma \) does not intersect the axes, \( cy^{2m} + dy^m + h \neq 0 \) because \( h > \frac{b^2 f}{4d} \), and \( ax^{2n} + bx^n + h \neq 0 \) because \( h > \frac{b^2 f}{4d} \), then the possible critical points on \( \Gamma \) are: \( A_1 \left( -\sqrt{\frac{2n-df}{2n-4df}}, -\sqrt{\frac{2m-bf}{2m-4bf}} \right), A_2 \left( -\sqrt{\frac{2n-df}{2n-4df}}, \sqrt{\frac{2m-bf}{2m-4bf}} \right), A_3 \left( \sqrt{\frac{2n-df}{2n-4df}}, -\sqrt{\frac{2m-bf}{2m-4bf}} \right), A_4 \left( \sqrt{\frac{2n-df}{2n-4df}}, \sqrt{\frac{2m-bf}{2m-4bf}} \right) \) when \( m \) and \( n \) are even numbers.

\( A_2, A_4 \) when \( m \) is odd and \( n \) is even.
We consider the equation (2.3) as
\[ cz^2 + (d + fx^n)z + \left(ax^n + bx^n + h\right) = 0 \text{ where } z = y^m \]
(3.4)
The discriminant \( \Delta = (\frac{f^2 - 4ac}{4ac-f})^2 + 2(df - 2bc)s + d^2 - 4ch \) where \( s = x^n \)
\[ \Delta'_A = \frac{4b^2c^2 - 4abcd - 16ac^2 + 4acd^2 + 4hcf^2}{4ac-f} \]
We note that if \( h > \frac{\sqrt{b^2c^2 - 4abc} + acd^2 - bcd f + hf^2 - 2bc + df}{4ac-f} \), \( \Delta'_A < 0 \), and if \( f^2 < 4ac \) then \( \Delta < 0 \), and there is no real solution of equation (2.3).

If \( h = \frac{\sqrt{b^2c^2 - 4abc} + acd^2 - bcd f + hf^2 - 2bc + df}{4ac-f} \), \( \Delta'_A = 0 \), and \( \Delta = \left(\frac{f^2 - 4ac}{4ac-f}\right) \left(s - \frac{2hcf^2}{f^2 - 4ac}\right)^2 < 0 \), with \( s \neq \frac{2hcf^2}{f^2 - 4ac} \), and there is no real solution of equation (2.3).

If \( h < \frac{\sqrt{b^2c^2 - 4abc} + acd^2 - bcd f + hf^2 - 2bc + df}{4ac-f} \), \( \Delta'_A > 0 \) and we have
\[ s_1 = \frac{1}{4ac-f}\left(2\sqrt{b^2c^2 - 4abc} + acd^2 - bcd f + hf^2 - 2bc + df\right) \]
\[ s_2 = \frac{1}{4ac-f}\left(-2\sqrt{b^2c^2 - 4abc} + acd^2 - bcd f + hf^2 - 2bc + df\right) \]
The expression
\[ \frac{1}{4ac-f}\left(2\sqrt{b^2c^2 - 4abc} + acd^2 - bcd f + hf^2 - 2bc + df\right) \]
is positive,
and if \( \frac{d}{ac} < h \), then the expression \( \frac{1}{4ac-f}\left(-2\sqrt{b^2c^2 - 4abc} + acd^2 - bcd f + hf^2 - 2bc + df\right) \) is also positive.
We distinguish the following cases

1. \( n \) is odd number
   The equation \( \Delta = 0 \) admits two real solutions
   \[ x_1 = \sqrt[4]{4ac-f}\left(2\sqrt{b^2c^2 - 4abc} + acd^2 - bcd f + hf^2 - 2bc + df\right) \]
   \[ x_2 = \sqrt[4]{4ac-f}\left(-2\sqrt{b^2c^2 - 4abc} + acd^2 - bcd f + hf^2 - 2bc + df\right) \]
   For \( x \in [x_1, x_2] \) the discriminant \( \Delta \) is positive and the equation (2.3) admits two real solutions
   \[ z_1 = \frac{-(d + fx^n) - \sqrt{(f^2 - 4ac)x^{2n} + 2(df - 2bc)x^n + d^2 - 4ch}}{2c} \]
   \[ z_2 = \frac{-(d + fx^n) + \sqrt{(f^2 - 4ac)x^{2n} + 2(df - 2bc)x^n + d^2 - 4ch}}{2c} \]
   As \( c > 0 \) and \( h > \frac{d^2}{ac} \), \( z_1, z_2 \) are positive.
   If \( m \) is odd number, they are two real solutions of equation (2.3) that depend on \( y \) which are
   \[ y_1 = \sqrt{\frac{-(d + fx^n) - \sqrt{(f^2 - 4ac)x^{2n} + 2(df - 2bc)x^n + d^2 - 4ch}}{2c}} \]
   \[ y_2 = \sqrt{\frac{-(d + fx^n) + \sqrt{(f^2 - 4ac)x^{2n} + 2(df - 2bc)x^n + d^2 - 4ch}}{2c}} \]
x → \( y_1 \) is decreasing function when \( x \in [x_1, x_0] \) and an increasing function when \( x \in [x_0, x_2] \)
x → \( y_2 \) is an increasing function when \( x \in [x_1, x_0] \) and a decreasing function when \( x \in [x_0, x_2] \)
As before, we conclude that, when

\[ \Gamma \]

is an even number, they are four real solutions of equation (2.3) that depend on

\[ x \]

\[ y \]

\[ z \]

\[ \in \]

\[ \mathbb{R} \]

\[ D \]

\[ x_1, x_2 \]

\[ x_0 \]

\[ y_1 \]

\[ y_2 \]

\[ y_1, y_2 \]

\[ y \in \mathbb{R} \]

\[ y_1, y_2, -y_1, -y_2 \]

\[ \Delta = 0 \]

\[ D_1 = \{ (x, y) \in \mathbb{R}^2, x_1 < x < x_2, y_1 (x_0) < y < y_2 (x_0) \} \]

\[ \Delta = 0 \]

\[ D_1, D_2, D_3, D_4 \]

\[ \Gamma \]

\[ \frac{\partial U}{\partial x} = \frac{\partial U}{\partial y} = nx^n (yP(x) + V(y)) (b + 2ax^n + fy^m) + my^m (xQ(y) + W(x)) (d + 2cy^n + fx^n) U \]

\[ K(x, y) = nx^n (yP(x) + V(y)) (b + 2ax^n + fy^m) + my^m (xQ(y) + W(x)) (d + 2cy^n + fx^n) \]

\[ \frac{\partial}{\partial x} \frac{\partial}{\partial y} \]

\[ \int_0^T \left( \frac{P(x) + V(y)}{y} \right) dx - \int_0^T \left( Q(y) + \frac{W(x)}{x} \right) dx \]

see for instance Giacomini & Grau[8].
**Explicit form of limit cycle**

**Reading data of system (3.1)**

**Existence of limit cycles**

1. The system \( x \) when there exist limit cycle its explicit form is

2. If the study is restricted to the realistic quadrant

3. **Example 5.1.**

4. **Algorithm**

   * Reading data of system (3.1)
   * Reading degrees \( m \) and \( n \) such that \( m > 0 \) and \( n > 0 \).
   * Reading coefficients \( a,b,c,d,f \), \( h \) such that \( a > 0, b < 0, c > 0, d < 0, f < 0 \) and \( f^2 < 4ac \).
   * Enter the odd polynomial functions \( P(x) \) and \( Q(y) \) with positive coefficients.
   * Enter the analytic functions \( V(x) \) and \( W(y) \).
   * Existence of limit cycles

   **Remark 3.2.** **Remark 3.3.**

5. **Examples**

   **Example 5.1.** Let \( m = n = 2, a = 2, b = -2, c = 2, d = -2, f = -2, h = 1 \), \( P(x) = x, Q(y) = y, V(y) = y + 1, W(x) = x - 1 \)

   \[
   \begin{align*}
   x &= x \\
   y &= y \\
   \end{align*}
   \]

   \[
   \begin{pmatrix}
   2x^5y + 2x^4y + 2x^3y^3 - 2x^3y - 2x^2y^3 + 2x^2y^2 - 2x^2y - 2x^2 \\
   + 2x^5 - 3x^4y + x^2y^3 - 6x^4 - 2y^4 - 2x^2y + y + 1 \\
   2x^5y + 2x^4y + 2x^3y^3 - 2x^3y - 2x^2y^3 + 2x^2y^2 - 2x^2y - 2x^2 + \\
   + 2x^5 - 3x^4y + x^2y^3 - 6x^4 - 2y^4 - 2x^2y + y + 1 \\
   \end{pmatrix}
   \]

   The system (5.1) admits four limit cycles represented by the curve \( 2x^4 - 2x^2 + 2y^2 + y^2 - 2 - 2x^2 \) + 1 = 0, and it has seven singular points, three are saddle points, two are stable focus and two are instable focus. The limit cycles in the first and third quadrant around stable focus and limit cycles in the second and fourth quadrant around unstable focus. Figure (5.1)
Example 5.2. Let \( m = 2, n = 1, a = 3, b = -2, c = 1, d = -3, f = -2, h = 3, P(x) = x^3, Q(y) = y^3, V(y) = -1, W(x) = 1 \)

\[
\begin{align*}
\dot{x} &= x \left( 3x^5y - 2x^4y^3 - 2x^4y + x^3y^5 - 3x^3y^2 + 3x^3y - 3x^2y - 3x^2 + 6xy^2 + 2x - 5y + 9y^2 - 3 \right) \\
\dot{y} &= y \left( 3x^3y^3 - 2x^2y^5 - 2x^2y^3 + 9x^2 + xy^2 - 3x^2y^2 + 3xy^3 - 3xy^2 - 4xy^2 + 4x + y^4 - 3y^2 + 3 \right)
\end{align*}
\]  

(5.2)

The system (5.2) admits two limit cycles represented by the curve \( 3x^2 - 2x + y^2 - 3y^2 - 2xy^2 + 3 = 0 \), and it has five singular points, three are saddle points, one is a stable focus, one is an unstable focus, the limit cycle in first quadrant encloses a stable focus, and the other encloses an unstable focus. Figure (5.2)

Example 5.3. Let \( m = n = 1, a = 2, b = -3, c = 1, d = -3, f = -1, h = 3, P(x) = \exp(x), Q(y) = \arctan(y), V(y) = y\sin(y), W(x) = x\cos(x) \)

\[
\begin{align*}
\dot{x} &= x \left( (y\exp(x) + y\sin(y)) \left( 2x^2 - 3x + y^2 - 3y - xy + 3 \right) - y(2y - x - 3) \right) \\
\dot{y} &= y \left( (x\arctan(y) + x\cos(x)) \left( 2x^2 - 3x + y^2 - 3y - xy + 3 \right) + x(4x - y - 3) \right)
\end{align*}
\]  

(5.3)

The system (5.3) admits one limit cycle, represented by the curve \( 2x^2 - 3x + y^2 - 3y - xy + 3 = 0 \), that enclosed a stable focus, figure (5.3).

Note that \( \frac{d(\exp(x))}{dx} + \frac{d(\arctan(y))}{dy} = e^x + \frac{1}{y + 1} > 0 \)

and

\[
\int_0^\infty K(x,y)dt = \int_0^\infty \int_0^\infty \frac{1}{\sqrt{3\pi}} e^{x^2 + 1/y^2 + 1} \left( e^x + \frac{1}{y + 1} \right) dxdy \approx 22.55.
\]

6. Conclusion

We proposed in this paper a class of Kolmogorov system, where just choose the parameters satisfying the conditions of Theorem 3.1, we conclude directly that the system has one, two or four limit cycles and we give them explicitly.
