ORTHOGONAL STRUCTURE ON A QUADRATIC CURVE

SHEEHAN OLVER AND YUAN XU

Abstract. Orthogonal polynomials on quadratic curves in the plane are studied. These include orthogonal polynomials on ellipses, parabolas, hyperbolas, and two lines. For an integral with respect to an appropriate weight function defined on any quadratic curve, an explicit basis of orthogonal polynomials is constructed in terms of two families of orthogonal polynomials in one variable. Convergence of the Fourier orthogonal expansions is also studied in each case. We discuss applications to the Fourier extension problem, interpolation of functions with singularities or near singularities, and the solution of Schrödinger’s equation with non-differentiable or nearly-non-differentiable potentials.

1. Introduction

The purpose of this work is to study orthogonal polynomials of two variables defined on a quadratic curve in the plane. Every quadratic curve in the plane satisfies an equation of the form

$$\gamma(x, y) := a_{1,1}x^2 + 2a_{1,2}xy + a_{2,2}y^2 + 2a_{1,3}x + 2a_{2,3}y + a_{3,3} = 0$$

for some constants $a_{i,k}$. Let $\Omega = \Omega_\gamma := \{(x, y) : \gamma(x, y) = 0\} \subset \mathbb{R}^2$ be the trace of the curve in the plane. Let $\varpi(x, y)$ be a nonnegative weight function defined on $\Omega$ satisfying $\int_\Omega \varpi(x, y)d\sigma(x, y) > 0$, where $d\sigma$ is the Lebesgue measure on the boundary $\Omega$. We consider the bilinear form defined by

$$\langle f, g \rangle = \int_\Omega f(x, y)g(x, y)\varpi(x, y)d\sigma(x, y).$$

Since $\langle f, g \rangle = 0$ if either $f$ or $g$ belongs to the polynomial ideal $\langle \gamma \rangle$, it is an inner product only on the space $\mathbb{R}[x, y]/\langle \gamma \rangle$; that is, polynomials modulo the ideal $\langle \gamma \rangle$.

When $\gamma(x, y) = 1 - x^2 - y^2$, so that $\Omega$ is the unit circle, the orthogonal structure is well-understood. In particular, when $\varpi(x, y) = 1$, the orthogonal polynomials are spherical harmonics, which are homogeneous polynomials of two variables, their restriction on the circle are $\cos(n\theta)$ and $\sin(n\theta)$ where $x = \cos \theta$ and $y = \sin \theta$, and the corresponding Fourier orthogonal expansions are the usual Fourier series. This case has served as the model for our recent study [9] of orthogonal polynomials on a wedge,

defined as two line segments that share a common endpoint. In this paper we shall construct orthogonal polynomials for other quadratic curves.

Under an affine change of variables, quadratic curves in the plane are classified into five classes; three non-degenerate cases: ellipses, parabolas, and hyperbolas; and two degenerate cases: two intersecting real lines, and two parallel real lines. Since an affine change of variables does not change the degree of a polynomial in two variables, we only need to study orthogonal polynomials on a standard quadratic curve for each class of quadratic curves. Our choice of standard quadratic curves are the following:

(i) ellipse: \( x^2 + y^2 = 1 \);
(ii) parabola: \( y = x^2 \);
(iii) hyperbola: \( x^2 - y^2 = 1 \);
(iv) two intersection lines: \( x = 0 \) and \( y = 0 \); and,
(v) parallel lines: \( y = -1 \) and \( y = 1 \).

As in the known cases of orthogonal polynomials on the unit circle and on a wedge, the space of orthogonal polynomials of degree \( n \) has dimension 2 when \( n \geq 1 \) for each quadratic curve. Assuming that \( \varpi \) satisfies certain symmetry properties, the two-dimensional space of orthogonal polynomials on each quadratic curve can be expressed in terms of two different families of orthogonal polynomials in one variable, whose structure is well-understood. Furthermore, we shall relate the Fourier orthogonal expansions on the quadratic curve to those on the real line so that the convergence of the former can be deduced from the latter. Our approach will follow closely the development in [9] and relies heavily on symmetry of the domain and the weight function.

We consider three applications of the results. The first is usage in the Fourier extension problem, essentially rephrasing the known results of [7, 6] in terms of the orthogonal polynomials on quadratic curves. The second application is interpolation of functions on the real line with singularities of the form \(|x|, \sqrt{x^2 + \epsilon^2}, \text{ and } 1/x\). For example, we consider functions on the interval \([-1, 1]\) of the form

\[
 f(x) = f(\sqrt{x^2 + \epsilon^2}, x)
\]

where \( f(x, y) \), defined on the hyperbola \( x^2 = y^2 + \epsilon^2 \), is entire in \( x \) and \( y \). We will see that we can calculate the two-variable polynomial interpolant of \( f(x, y) \) using orthogonal polynomials via a suitably constructed quadrature rule. The resulting approximation converges super-exponentially fast, at a rate that is uniformly bounded as \( \epsilon \to 0 \). This is in contrast to using only univariate orthogonal polynomials (e.g. an interpolant at Chebyshev points) whose convergence degenerates to algebraic as \( \epsilon \to 0 \), as the convergence rate is dictated by the size of the Bernstein ellipse in the complex plane in which \( f(x) \) is analytic. The final application is solving Schrödinger’s equation when the potential is singular or nearly singular. In particular, we consider the equation

\[
 -0.1^2 u''(t) + V(t)u = \lambda u
\]

with \( V(t) = \sqrt{t^2 + \epsilon^2} + (t - 0.1)^2 \) using Dirichlet conditions, showing that the eigenstates can be calculated robustly for small \( \epsilon \) by using a basis built out of orthogonal polynomials on the hyperbola.

The paper is organized as follows. The next section is preliminary, where we fix notations and lay down the groundwork. Orthogonal structure on the quadratic curves will be discussed in the next five sections, from Section 3 to Section 7, each standard quadratic curve is treated in its own section, in the order of (i) – (v). In Section 8 we
show that interpolation with this basis is feasible via suitably constructed quadrature rules. Applications of the results are investigated in Section 9.

2. Preliminary

Any second degree curve in the plane satisfies an equation of the form

$$\gamma(x, y) := a_{1,1}x^2 + 2a_{1,2}xy + a_{2,2}y^2 + 2a_{1,3}x + 2a_{2,3}y + a_{3,3} = 0.$$ 

Let \( A = (a_{i,j})_{i,j=1}^3 \) with \( a_{j,i} := a_{i,j} \). The curve is called non-degenerate if \( \det(A) \neq 0 \) and degenerate if \( \det(A) = 0 \). Let \( \Delta := a_{1,1}a_{2,2} - a_{1,2}^2 \). In the non-degenerate case, there are three classes of curves, ellipse \((\Delta > 0)\), parabola \((\Delta = 0)\), and hyperbola \((\Delta < 0)\). In the degenerate case, there are two classes, two intersecting real lines \((\Delta > 0)\) and two parallel lines \((\Delta = 0)\). In the last case, we assume that the two parallel lines are distinct. If the two lines coincide, then an appropriate rotation and translation reduces the problem to the real line. Orthogonal polynomials on the real line have been studied extensively and are well-understood (cf. \[13]\).

Let \( \Pi_n^2 \) denote the space of polynomials of degree at most \( n \) in two real variables. Let \( \gamma \) be a quadratic curve. With respect to the bilinear form \((1.1)\) defined on \( \gamma \), a polynomial \( P \in \Pi_n^2 \) is called an orthogonal polynomial on the quadratic curve \( \gamma \) if \( \langle P, Q \rangle = 0 \) for all polynomials \( Q \in \Pi_m^2 \) with \( m < n \) and \( \langle P, P \rangle > 0 \). Let \( \mathcal{H}_n = \mathcal{H}_n(\pi) \subset \Pi_n^2 \) be the space of orthogonal polynomials of degree \( n \) on the quadratic curve.

As mentioned in the introduction, we only need to consider a standard quadratic curve for each class. For each quadratic curve \( \gamma \) in (i) – (v), the bilinear form \((1.1)\) defined on \( \Omega_\gamma \) is an inner product on the space \( \mathbb{R}[x, y]/\langle \gamma \rangle \) of polynomials modulo the ideal \( \langle \gamma \rangle \). Using the explicit formula of \( \gamma \) for each standard form, it is easy to see that the following proposition holds.

Proposition 2.1. The space \( \mathcal{H}_n \) has dimension \( \dim \mathcal{H}_0 = 1 \) and \( \dim \mathcal{H}_n = 2 \) for \( n \geq 1 \).

An explicit basis for the space \( \mathcal{H}_n \) will be constructed for each class of quadratic curves in Sections 3–7. Let \( \{Y_{n,1}, Y_{n,2}\} \) be an orthogonal basis of \( \mathcal{H}_n \). Then these two polynomials are orthogonal to all polynomials of lower degrees and they are orthogonal to each other. Let \( L^2(\pi, \Omega) \) be the \( L^2 \) space of Lebesgue integrable functions with finite norm \( \|f\| = \langle f, f \rangle^{1/2} \). For \( f \in L^2(\pi, \Omega) \) its Fourier orthogonal series is defined by

$$f = \hat{f}_0 + \sum_{n=1}^{\infty} \left[ \hat{f}_{n,1}Y_{n,1} + \hat{f}_{n,2}Y_{n,2} \right],$$

where

$$\hat{f}_0 := \frac{\langle f, 1 \rangle}{\langle 1, 1 \rangle} \quad \text{and} \quad \hat{f}_{n,i} := \frac{\langle f, Y_{n,i} \rangle}{\langle Y_{n,i}, Y_{n,i} \rangle}, \quad n \geq 1.$$ 

The partial sum operator \( S_n f \) is defined by

$$S_n f := \hat{f}_0 + \sum_{k=1}^{n} \left[ \hat{f}_{k,1}Y_{k,1} + \hat{f}_{k,2}Y_{k,2} \right].$$

We shall study the convergence of the Fourier orthogonal series on quadratic curves.

Our construction of orthogonal polynomials on the quadratic curves will heavily use orthogonal polynomials on the real line. Let \( w \) be a nonnegative weight function on
We let $p_n(w)$ denote an orthogonal polynomial of degree $n$ with respect to $w$ and let $h_n(w)$ denote the norm square of $p_n(w)$; more precisely,

$$\int_{\mathbb{R}} p_n(w;x)p_m(w;x)w(x)dx = h_n(w)\delta_{m,n}.$$ 

Let $L^2(w)$ denote the $L^2$ space with respect to $w$ on $\mathbb{R}$. The Fourier orthogonal series of $f \in L^2(w)$ is defined by

$$(2.3) \quad f = \sum_{n=1}^{\infty} \hat{f}_n(w)p_n(w) \quad \text{with} \quad \hat{f}_n(w) = \frac{1}{h_n(w)} \int_{\mathbb{R}} f(y)p_n(w;y)w(y)dy.$$ 

The Parseval identity implies that

$$\|f\|_{L^2(w,[0,1])}^2 = \sum_{n=0}^{\infty} |\hat{f}_n(w)|^2 h_n(w).$$ 

The $n$-th partial sum of the Fourier orthogonal series with respect to $w$ is defined as

$$(2.4) \quad s_n(w;f)(x) := \hat{f}_0(w)p_0(w;x) + \sum_{k=1}^{n} \hat{f}_k(w)p_k(w;x).$$ 

Our study of the Fourier orthogonal series on a quadratic curve consists of reducing the problem to that of the Fourier orthogonal series on $\mathbb{R}$.

### 3. Orthogonal polynomials on an ellipse

Each ellipse can be transformed to the unit circle under an affine transform. Hence, we only need to consider the circle

$$\Omega = \{(x,y) : x^2 + y^2 = 1 \in \mathbb{R}\} = \{(\cos \theta, \sin \theta) : \theta \in [0,2\pi]\}.$$ 

Orthogonal polynomials on circles are well studied. However, it should be pointed out that we are considering them as real polynomials in two variables, which are distinct from the thoroughly studied Orthogonal Polynomials on the Unit Circle (OPUC) [11]. The latter are analytic polynomials in a complex $z$ variable and orthogonal with respect to an inner product defined on the unit circle in the complex plane. In our results, they are restrictions of homogeneous polynomials of two variables on the unit circle in $\mathbb{R}^2$. The result below is well–known, we include it here for completeness and also as an opening to our study for other quadratic curves.

Let $w$ be an even nonnegative weight function defined on $[-1,1]$. We consider the bilinear form defined by

$$(3.1) \quad \langle f, g \rangle = \int_{-\pi}^{\pi} f(\cos \theta, \sin \theta)g(\cos \theta, \sin \theta)w(\cos \theta)\,d\theta$$

$$= \int_{-1}^{1} \left[ f(x, \sqrt{1-x^2})g(x, \sqrt{1-x^2}) + f(x, -\sqrt{1-x^2})g(x, -\sqrt{1-x^2}) \right] \frac{w(x)}{\sqrt{1-x^2}} \,dx$$

which defines an inner product on the space $\mathbb{R}[x,y]/(x^2 + y^2 - 1)$.

Let $P_n$ denote the space of homogeneous polynomials in two variables. Let $\mathcal{H}_n(w)$ denote the space of orthogonal polynomials of degree $n$ with respect to this inner product.
Theorem 3.1. Let $w(t)$ be an even weight function defined on $[-1, 1]$. Define $w_{-\frac{1}{2}}(t) = (1 - t^2)^{-\frac{1}{2}}w(t)$ and $w_{\frac{1}{2}}(t) = (1 - t^2)^{\frac{1}{2}}w(t)$. The polynomials
\begin{equation}
Y_{n,1}(x,y) = p_n(w_{-\frac{1}{2}}; x) \quad \text{and} \quad Y_{n,2}(x,y) = y p_{n-1}(w_{\frac{1}{2}}; x)
\end{equation}
are homogeneous polynomials of degree $n$ in $(x,y)$ and they form an orthogonal basis of $\mathcal{H}_n(\varpi)$ for all $n \geq 1$. Furthermore,
\begin{equation}
\langle Y_{n,1}, Y_{n,1} \rangle = 2 h_n(w_{-\frac{1}{2}}) \quad \text{and} \quad \langle Y_{n,2}, Y_{n,2} \rangle = 2 h_{n-1}(w_{\frac{1}{2}}).
\end{equation}

Proof. This result is known; see, for example, [3, Section 4.2]. We give an outline of the proof for completeness. Since $w(t)$ is even, the polynomial $p_n(w; t)$ is an even polynomial if $n$ is even and an odd polynomial if $n$ is odd. Consequently, it is easy to see that both $Y_{n,1}$ and $Y_{n,2}$ are homogeneous polynomials of degree $n$ in $(x,y)$. Since $\sin \theta$ is odd, it follows readily that $\langle Y_{n,1}, Y_{n,2} \rangle = 0$ for all $n \geq 0$ and $m \geq 1$. Moreover,
\begin{equation}
\langle Y_{n,1}, Y_{n,1} \rangle = 2 \int_{-1}^{1} \left[ p_n(w_{-\frac{1}{2}}; t) \right]^2 \frac{w(t)}{\sqrt{1-t^2}} dt = 2 h_n(w_{-\frac{1}{2}})
\end{equation}
and, similarly, $\langle Y_{n,2}, Y_{n,2} \rangle = 2 h_{n-1}(w_{\frac{1}{2}})$. \hfill \square

The most well-known example are the spherical harmonics, for which $w(t) = 1$. The orthogonal polynomials are
\begin{align*}
Y_{n,1}(x,y) &= \cos n\theta = T_n(x), \\
Y_{n,2}(x,y) &= \sin n\theta = yU_{n-1}(x),
\end{align*}
where $T_n(t)$ and $U_n(t)$ are the Chebyshev polynomials of the first and the second kind, respectively. The restrictions of $Y_{n,1}$ and $Y_{n,2}$ to the circle are the eigenfunctions of $d^2/d\theta^2$ (which is the Laplace–Beltrami operator on the circle) in the sense that they satisfy $w'(\theta) = -n w(\theta)$.

Another family of examples are $h$-harmonics associated with the dihedral group $I_k$ of $k$-regular polygons in the plane (cf. [3, Section 7.6]). For $k = 1, 2, \ldots$, the weight function in (3.1) is defined by
\begin{equation}
w(\cos \theta) = |\sin(k\theta)|^{2\alpha} |\cos(k\theta)|^{2\beta}, \quad \alpha, \beta \geq 0.
\end{equation}
For each $k$, the corresponding polynomials $Y_{n,1}$ and $Y_{n,2}$ are the eigenfunctions of a second order differential-difference operator on the circle [3, Section 7.6].

We can connect the Fourier orthogonal series on the circle to the Fourier orthogonal series in terms of $w_{-\frac{1}{2}}$ and $w_{\frac{1}{2}}$ on the interval $[-1, 1]$. Recall the definition of partial sum operators defined in (2.2) and (2.4).

Theorem 3.2. Let $f$ be a function defined on $\Omega$. Define
\begin{equation}
f_e(x) := \frac{f(x, \sqrt{1-x^2}) + f(x, -\sqrt{1-x^2})}{2}
\end{equation}
and
\begin{equation}
f_o(x) := \frac{f(x, \sqrt{1-x^2}) - f(x, -\sqrt{1-x^2})}{2 \sqrt{1-x^2}}.
\end{equation}
Then
\begin{equation}
S_n f(x, y) = s_n(w_{-\frac{1}{2}}; f_e, x) + y s_{n-1}(w_{\frac{1}{2}}; f_o, x).
\end{equation}
In particular, if \( s_n(w_{-\frac{1}{2}}; f_e, x) \to f_e(x) \) and \( s_{n-1}(w_{-\frac{1}{2}}; f_o, x) \to f_o(x) \) as \( n \to \infty \), then 
\( S_n(f, x, y) \to f(x, y) \) as \( n \to \infty \). Furthermore, if \( f \in L^2(\omega, \Omega) \), then
\[
\| f - S_n(f) \|_{L^2(w_{-\frac{1}{2}})}^2 = \| f - s_n(w_{-\frac{1}{2}}; f_e) \|_{L^2(w_{-\frac{1}{2}})}^2 + \| f_o - s_{n-1}(w_{\frac{1}{2}}; f_o) \|_{L^2(w_{\frac{1}{2}})}^2.
\]

\textbf{Proof.} By the expression of \( Y_{n,1} \) in \textbf{(3.2)},
\[
\langle f, Y_{n,1} \rangle = \int_{-\pi}^{\pi} f(\cos \theta, \sin \theta) p_n(w_{-\frac{1}{2}}; \cos \theta) w(\cos \theta) \, d\theta
\]
\[
= \int_{0}^{\pi} \left[ f(\cos \theta, \sin \theta) + f(\cos \theta, -\sin \theta) \right] p_n(w_{-\frac{1}{2}}; \cos \theta) w(\cos \theta) \, d\theta
\]
\[
= 2 \int_{-1}^{1} f_e(t) p_n(w_{-\frac{1}{2}}; t) w_{-\frac{1}{2}}(t) \, dt = 2 \langle f_e, p_n(w_{-\frac{1}{2}}) \rangle_{L^2(w_{-\frac{1}{2}})}.
\]

Similarly, by the expression of \( Y_{n,2} \) in \textbf{(3.2)},
\[
\langle f, Y_{n,2} \rangle = \int_{0}^{\pi} \left[ f(\cos \theta, \sin \theta) - f(\cos \theta, -\sin \theta) \right] \sin \theta p_{n-1}(w_{\frac{1}{2}}; \cos \theta) w(\cos \theta) \, d\theta
\]
\[
= \int_{0}^{\pi} f(\cos \theta, \sin \theta) - f(\cos \theta, -\sin \theta) \sin^2 \theta p_{n-1}(w_{\frac{1}{2}}; \cos \theta) w(\cos \theta) \, d\theta
\]
\[
= 2 \int_{-1}^{1} f_o(t) p_{n-1}(w_{\frac{1}{2}}; t) w_{\frac{1}{2}}(t) \, dt = 2 \langle f_o, p_{n-1}(w_{\frac{1}{2}}) \rangle_{L^2(w_{\frac{1}{2}})}.
\]

Consequently, by \textbf{(3.3)}, we obtain
\[
\hat{f}_{n,1} = \frac{\langle f_e, p_n(w_{-\frac{1}{2}}) \rangle_{L^2(w_{-\frac{1}{2}})}}{h_n(w_{-\frac{1}{2}})} = \hat{f}_{e,n}(w_{-\frac{1}{2}}), \quad \hat{f}_{n,2} = \frac{\langle f_o, p_{n-1}(w_{\frac{1}{2}}) \rangle_{L^2(w_{\frac{1}{2}})}}{h_{n-1}(w_{\frac{1}{2}})} = \hat{f}_{o,n-1}(w_{\frac{1}{2}})
\]
in the notation of \textbf{(2.3)}. Hence, \textbf{(3.4)} follows readily from the definition of the partial sum operators in \textbf{(2.2)}.

With \( y = \sqrt{1 - x^2} \), we see that \( f(x, y) = f_e(x) + y f_o(x) \). It follows that
\[
f(x, y) - S_n(f, x, y) = f_e(x) - s_n(w_{-\frac{1}{2}}; f_e, x) + y \left( f_o(x) - s_{n-1}(w_{\frac{1}{2}}; f_o, x) \right).
\]

Consequently, the convergence of \( S_n(f) \) follows form that of \( s_n(w_{-\frac{1}{2}}; f_e) \) and \( s_{n-1}(w_{\frac{1}{2}}; f_o) \). Finally, let \( F = f_e - s_n(w_{-\frac{1}{2}}; f_e) \) and \( G = f_o - s_{n-1}(w_{\frac{1}{2}}; f_o) \). Then the last displayed identity shows that
\[
\| f - S_n(f) \|_{L^2(\omega, \Omega)}^2 = \int_{-\pi}^{\pi} |F(\cos \theta) + \sin \theta G(\cos \theta)|^2 w(\cos \theta) \, d\theta
\]
\[
= \int_{-\pi}^{\pi} (|F(\cos \theta)|^2 + |\sin \theta G(\cos \theta)|^2) w(\cos \theta) \, d\theta
\]
\[
= \int_{-1}^{1} |F(t)|^2 w_{-\frac{1}{2}}(t) \, dt + \int_{-1}^{1} |G(t)|^2 w_{\frac{1}{2}}(t) \, dt,
\]
where we have used the fact that the integral of \( \sin \theta F(\cos \theta) G(\cos \theta) \) is zero in the second step. This gives \textbf{(3.5)} and completes the proof.

This theorem is also known but probably not stated in this precise form. When \( f \) is chosen as \( f(x, y) = g(\cos \theta) \), then the Fourier orthogonal series of \( f \) becomes the Fourier orthogonal series of \( g \) in \( L^2(w; [-1, 1]) \). For the classical Fourier series, it is the familiar fact that the Fourier series of \( f(\cos \theta) \) is the Fourier cosine series of \( f(t) \).
We choose to give a complete proof here since it is the harbinger of what will come for other quadratic curves.

4. Orthogonal polynomials on a parabola

Under an affine transform, we only need to consider the parabola defined by
\[ y = x^2 \quad \text{or} \quad \Omega = \{(x, y) : y = x^2, x \in \mathbb{R}\}, \]
and consider even weights \( w(x, y) = w(-x, y) \). Since \( y = x^2 \), we can write \( w(x, y) = w(x^2) \) for a weight function \( w \) on \( \mathbb{R}_+ = [0, +\infty) \), so that the bilinear form becomes
\[
\langle f, g \rangle = \int_{\mathbb{R}} f(x, x^2)g(x, x^2)w(x^2)dx,
\]
which defines an inner product on the space \( \mathbb{R}[x, y]/(y - x^2) \).

4.1. Orthogonal polynomials. Let \( \mathcal{H}_n(w) \) denote the space of orthogonal polynomials of degree \( n \) with respect to the inner product \( \langle f, g \rangle \).

**Theorem 4.1.** Let \( w \) be a weight function defined on \( \mathbb{R}_+ \). Define \( w_{-\frac{1}{2}}(t) := t^{\frac{1}{2}}w(t) \) and \( w_{\frac{1}{2}}(t) := t^{-\frac{1}{2}}w(t) \). Then the polynomials
\[
Y_{n,1}(x, y) = p_n(w_{-\frac{1}{2}}; y) \quad \text{and} \quad Y_{n,2}(x, y) = xp_{n-1}(w_{\frac{1}{2}}; y)
\]
form an orthogonal basis of \( \mathcal{H}_n(w) \) for \( n \geq 1 \). Furthermore,
\[
\langle Y_{n,1}, Y_{n,1} \rangle = h_n(w_{-\frac{1}{2}}) \quad \text{and} \quad \langle Y_{n,2}, Y_{n,2} \rangle = h_{n-1}(w_{\frac{1}{2}}).
\]

**Proof.** For \( n \geq 0 \) and \( m \geq 0 \),
\[
\langle Y_{n,1}, Y_{m,2} \rangle = \int_{\mathbb{R}} Y_{n,1}(x, x^2)Y_{m,2}(x, x^2)w(x^2)dx
\]
\[= \int_{\mathbb{R}} xp_n(w_{-\frac{1}{2}}, x^2)p_{n-1}(w_{\frac{1}{2}}, x^2)w(x^2)dx = 0
\]
since the integrand is odd. For \( n, m \in \mathbb{N}_0 \),
\[
\langle Y_{n,1}, Y_{m,1} \rangle = \int_{\mathbb{R}} p_n(w_{-\frac{1}{2}}, x^2)p_m(w_{-\frac{1}{2}}, x^2)w(x^2)dx
\]
\[= 2\int_0^{\infty} p_n(w_{-\frac{1}{2}}, x^2)p_m(w_{-\frac{1}{2}}, x^2)w(x^2)dx
\]
\[= \int_0^{\infty} p_n(w_{-\frac{1}{2}}, t)p_m(w_{-\frac{1}{2}}, t)t^{-\frac{1}{2}}w(t)dt = h_n(w_{-\frac{1}{2}})\delta_{n,m}.
\]

Similarly, for \( n, m \in \mathbb{N} \),
\[
\langle Y_{n,2}, Y_{m,2} \rangle = \int_{\mathbb{R}} x^2p_{n-1}(w_{\frac{1}{2}}, x^2)p_{m-1}(w_{\frac{1}{2}}, x^2)w(x^2)dx
\]
\[= \int_0^{\infty} p_{n-1}(w_{\frac{1}{2}}, t)p_{m-1}(w_{\frac{1}{2}}, t)t^{\frac{1}{2}}w(t)dt = h_{n-1}(w_{\frac{1}{2}})\delta_{n,m}.
\]
Since it is evident that \( Y_{n,1} \) and \( Y_{n,2} \) are polynomials of degree \( n \) in two variables, we see that they form an orthogonal basis for \( \mathcal{H}_n(w) \).

We consider two examples of classical orthogonal polynomials. Our first example is on the entire parabola \( \{(x, y) : y = x^2, x \in \mathbb{R}\} \) with the Hermite weight \( w(t) = e^{-t^2} \). Let \( L_n^\alpha \) denote the Laguerre polynomials, which are orthogonal with respect to \( x^\alpha e^{-x} \) on \( \mathbb{R}_+ \).
Proposition 4.2. For the inner product with respect to the Hermite weight

\[ \langle f, g \rangle = \int_{\mathbb{R}} f(x, x^2) g(x, x^2) e^{-x^2} \, dx \]

and \( n \geq 1 \), an orthogonal basis of \( \mathcal{H}_n \) is given by the polynomials

\[ Y_{n,1}(x, y) = L_n^{\frac{-1}{2}}(y) \quad \text{and} \quad Y_{n,2}(x, y) = x L_n^{\frac{1}{2}}(y). \]

Furthermore, they are the eigenfunctions of a second order differential operator; more precisely, \( Y_{n,1} \) and \( Y_{n,2} \) satisfy the equation

\[ Lu := x \partial_{xy} u + y \partial_y u + (\frac{1}{2} - y) \partial_y u - x \partial_x u = -nu. \]

Proof. We only need to verify the differential equations. The Laguerre polynomial \( v(y) = L_n^\alpha(y) \) satisfies the equation

\[ v'' + (\alpha + 1 - y)v' = -nv. \]

For \( u = Y_{n,1} \), we have \( \partial_x u = 0 \) and it is easy to see that (4.4) becomes the differential equation for \( v(y) = L_n^{\frac{1}{2}}(y) \). For \( u = Y_{n,2} \), we write \( u(x, y) = xv(y) \) with \( v(y) = L_n^{\frac{1}{2}}(y) \). Then

\[ Lu = xv' + xyv'' + (\frac{1}{2} - y) xv' - xv = x(v'' + (\frac{3}{2} - y)v') - xv = x(-(n - 1)v - v) = -nv = -nu. \]

This completes the proof. \( \Box \)

Our second example is over the parabola with the Gegenbauer weight \( w(t) = (1 - t^2)^{\lambda - \frac{1}{2}} \chi_{[-1,1]}(t) \), where \( \chi_E \) denotes the characteristic function of the set \( E \). The support set of \( w \) is finite, so that our orthogonal polynomials are over a finite parabola \( \{(x, y) : y = x^2, x \in [-1,1]\} \). Let \( P_n^{(\alpha, \beta)} \) denote the Jacobi polynomials, which are orthogonal with respect to the weight function \( (1 - x)^\alpha(1 + x)^\beta \) on the interval \([-1,1]\).

Proposition 4.3. For the inner product with respect to the Gegenbauer weight

\[ \langle f, g \rangle = \int_{-1}^{1} f(x, x^2) g(x, x^2) (1 - x^2)^{\lambda - \frac{1}{2}} \, dx \]

and \( n \geq 1 \), an orthogonal basis of \( \mathcal{H}_n \) is given by the polynomials

\[ Y_{n,1}(x, y) = P_n^{(\lambda - \frac{1}{2}, -\frac{1}{2})}(2y - 1) \quad \text{and} \quad Y_{n,2}(x, y) = x P_n^{(\lambda - \frac{1}{2}, \frac{1}{2})}(2y - 1). \]

Proof. Since the polynomial \( P_n^{(\lambda - \frac{1}{2}, -\frac{1}{2})}(2t - 1) \) is orthogonal with respect to \( t^{\frac{-1}{2}}(1 - t)^{\lambda - \frac{1}{2}} \) on \([0,1]\) and the polynomial \( P_n^{(\lambda - \frac{1}{2}, \frac{1}{2})}(2t - 1) \) is orthogonal with respect to \( t^{\frac{1}{2}}(1 - t)^{\lambda - \frac{1}{2}} \) on \([0,1]\), we see that \( Y_{n,1} \) and \( Y_{n,2} \) form a basis of \( \mathcal{H}_n \). \( \Box \)

It is known that the Jacobi polynomial \( v(t) = P_n^{(\alpha, \beta)}(2t - 1) \) satisfies the differential equation

\[ t(1 - t)v'' + (\beta + 1 - (\alpha + \beta + 2)t)v' = -n(n + \alpha + \beta + 1)v. \]

However, since the eigenvalues are quadratic in \( n \), we cannot combine terms as in the proof of (4.4) when working with \( Y_{n,2} \) and, as a consequence, we are not able to deduce a second order differential operator that has \( Y_{n,1} \) and \( Y_{n,2} \) as eigenfunctions with the same eigenvalue.
4.2. **Fourier orthogonal series.** Let \( L^2(\varpi, \Omega) \) be the \( L^2 \) space on \( \Omega \) with the norm \( \| \cdot \|_{L^2(\varpi, \Omega)} \) defined by

\[
\| f \|_{L^2(\varpi, \Omega)}^2 := \langle f, f \rangle = \int_{\mathbb{R}} |f(x, x^2)|^2 w(x^2) \, dx.
\]

For \( f \in L^2(\varpi, \Omega) \), we consider the Fourier orthogonal series with respect to the basis \( \{ 4.2 \} \) as defined in \( (2.1) \).

**Theorem 4.4.** Let \( f \) be a function defined on \( \Omega \). Define

\[
f_c(y) := \frac{f(\sqrt{y}, y) + f(-\sqrt{y}, y)}{2} \quad \text{and} \quad f_o(y) := \frac{f(\sqrt{y}, y) - f(-\sqrt{y}, y)}{2\sqrt{y}}.
\]

Then

\[
(4.5) \quad S_n f(x, y) = s_n(w_{-\frac{1}{2}}; f_c, y) + x s_{n-1}(w_{\frac{1}{2}}; f_o, y).
\]

In particular, if \( s_n(w_{-\frac{1}{2}}; f_c) \to f_c \) and \( s_{n-1}(w_{\frac{1}{2}}; f_o) \to f_o \) as \( n \to \infty \), then \( S_n f(x, y) \to f(x, y) \) as \( n \to \infty \). Furthermore, if \( f \in L^2(\varpi, \Omega) \), then

\[
\| f - S_n(f) \|_{L^2(\varpi, \Omega)}^2 = \| s_{n}(w_{-\frac{1}{2}}; f_c) - f_c \|_{L^2(w_{-\frac{1}{2}})}^2 + \| s_{n-1}(w_{\frac{1}{2}}; f_o) - f_o \|_{L^2(w_{\frac{1}{2}})}^2.
\]

**Proof.** The proof is similar to that of Theorem 3.2. We shall be brief. By the expression of \( Y_{n,1} \) in \( (4.2) \),

\[
\langle f, Y_{n,1} \rangle = \int_{\mathbb{R}} f(x, x^2) p_n(w_{-\frac{1}{2}}; x^2) w(x^2) \, dx
\]

\[
= \int_{0}^{\infty} \left[ f(x, x^2) + f(-x, x^2) \right] p_n(w_{-\frac{1}{2}}; x^2) w(x^2) \, dx
\]

\[
= \int_{0}^{\infty} f_c(y)p_n(w_{-\frac{1}{2}}; y)\sqrt{y}^{-\frac{3}{2}} w(y) \, dy = \langle f_c, p_n(w_{-\frac{1}{2}}) \rangle_{L^2(w_{-\frac{1}{2}})}.
\]

Similarly, by the expression of \( Y_{n,2} \) in \( (4.2) \), we can derive

\[
\langle f, Y_{n,2} \rangle = \langle f_o, p_{n-1}(w_{\frac{1}{2}}) \rangle_{L^2(w_{\frac{1}{2}})}.
\]

Consequently, by \( (4.3) \), we obtain

\[
\hat{f}_{n,1} = \langle \hat{f}_c \rangle_{n}(w_{-\frac{1}{2}}) \quad \text{and} \quad \hat{f}_{n,2} = \langle \hat{f}_o \rangle_{n-1}(w_{\frac{1}{2}})
\]

in the notation of \( (2.3) \), from which \( (4.5) \) follows.

The rest of the proof follows from \( f(x, x^2) = f_c(x^2) + x f_o(x^2) \), which shows that

\[
f(x, x^2) - S_n f(x, x^2) = f_c(x^2) - s_n(w_{-\frac{1}{2}}; f_c, x^2) + x \left( f_o(x^2) - s_{n-1}(w_{\frac{1}{2}}; f_o, x^2) \right)
\]

and its two terms in the right-hand side have different parity, since the two functions in the brackets are obviously even functions.

\[\square\]

5. **Orthogonal polynomials on a hyperbola curve**

Under an affine transform, we only need to consider the hyperbola defined by

\[
x^2 - y^2 = 1 \quad \text{or} \quad \Omega = \{(x, y) : x^2 - y^2 = 1\}.
\]

The resulted quadratic curves has two branches. We consider two cases.
5.1. **Ω with two branches.** We consider the bilinear form defined for both branches of the hyperbola \( x^2 = y^2 + 1 \) and consider

\[
\Omega = \left\{ \left( \sqrt{y^2 + 1}, y \right) : y \in \mathbb{R} \right\} \cup \left\{ - \left( \sqrt{y^2 + 1}, y \right) : y \in \mathbb{R} \right\}.
\]

For weights satisfying \( \varpi(x, y) = \varpi(-x, y) \), even in \( x \), we can use \( x^2 = y^2 + 1 \) and write \( \varpi(x, y) = w(y) \) for some \( w \) defined on \( \mathbb{R} \). We then consider the bilinear form

\[
\langle f, g \rangle = \int_{-\infty}^{\infty} \left[ f(\sqrt{y^2 + 1}, y)g(\sqrt{y^2 + 1}, y) + f(-\sqrt{y^2 + 1}, y)g(-\sqrt{y^2 + 1}, y) \right] w(y)dy,
\]

which is an inner product on \( \mathbb{R}[x, y]/(x^2 - y^2 - 1) \). Again let \( \mathcal{H}_n(\varpi) \) be the space of orthogonal polynomials of degree \( n \) with respect to the inner product \( \langle \cdot, \cdot \rangle \).

**Theorem 5.1.** Let \( w \) be a weight function on \( \mathbb{R} \) and let \( w_1(t) := (1 + t^2)w(t) \). Then the polynomials

\[
Y_{n,1}(x, y) = p_n(w; y) \quad \text{and} \quad Y_{n,2}(x, y) = xp_{n-1}(w; y)
\]

form an orthogonal basis of \( \mathcal{H}_n(\varpi) \) for \( n \geq 1 \). Furthermore,

\[
\langle Y_{n,1}, Y_{n,1} \rangle = 2h_n(w) \quad \text{and} \quad \langle Y_{n,2}, Y_{n,2} \rangle = 2h_{n-1}(w_1).
\]

**Proof.** For \( n \geq 0 \) and \( m \geq 1 \), we have

\[
\langle Y_{n,1}, Y_{m,2} \rangle = \int_{-\infty}^{\infty} p_n(w; y)p_{m-1}(w; y)\left( \sqrt{y^2 + 1} - \sqrt{y^2 + 1} \right) w(y)dy = 0.
\]

Furthermore, for \( n, m \in \mathbb{N}_0 \),

\[
\langle Y_{n,1}, Y_{m,1} \rangle = 2\int_{-\infty}^{\infty} p_n(w; y)p_m(w; y)w(y)dy = 2h_n(w)\delta_{n,m}
\]

and, for \( n, m \in \mathbb{N} \),

\[
\langle Y_{n,2}, Y_{m,2} \rangle = 2\int_{-\infty}^{\infty} p_{n-1}(w; y)p_{m-1}(w; y)(1 + y^2)w(y)dy = 2h_{n-1}(w_1)\delta_{n,m}
\]

since \( w_1 = (1 + \{\cdot\}^2)w \). This completes the proof. \( \square \)

If \( w \) is an even function on \( \mathbb{R} \), the orthogonal polynomial \( p_{n-1}(w; \cdot) \) can be constructed explicitly as shown in the following proposition.

**Proposition 5.2.** Let \( w_1(t) := (1 + t^2)w(t^2) \) define \( w_{-\frac{1}{2}}(t) = t^{-\frac{1}{2}}w(t) \) and \( w_{\frac{1}{2}}(t) = t^{\frac{1}{2}}w(t) \). Then

\[
p_{2n}(w_1; t) = \frac{1}{1 + t^2} \left( p_{n+1}(w_{-\frac{1}{2}}; t^2)p_n(w_{-\frac{1}{2}}; -1) - p_{n+1}(w_{-\frac{1}{2}}; 1)p_n(w_{-\frac{1}{2}}; t^2) \right),
\]

\[
p_{2n+1}(w_1; t) = \frac{t}{1 + t^2} \left( p_{n+1}(w_{\frac{1}{2}}; t^2)p_n(w_{\frac{1}{2}}; -1) - p_{n+1}(w_{\frac{1}{2}}; 1)p_n(w_{\frac{1}{2}}; t^2) \right).
\]

**Proof.** Changing variables \( s = t^2 \), we obtain

\[
\int_{\mathbb{R}} f(t^2)g(t^2)w_1(t)dt = \int_{0}^{\infty} f(s)g(s)(1 + s)s^{-\frac{1}{2}}w(s)ds,
\]

from which it is easy to see that

\[
p_{2n}(w_1; t) = p_n((1 + \{\cdot\})w_{-\frac{1}{2}}; t^2) \quad \text{and} \quad p_{2n+1}(w_1; t) = tp_n((1 + \{\cdot\})w_{\frac{1}{2}}; t^2).
\]
The orthogonal polynomials for \((1 + t)\frac{w - \frac{1}{2}}{\sqrt{y^2 + 1}}\) and \((1 + t)\frac{w + \frac{1}{2}}{\sqrt{y^2 + 1}}\) can be expressed by those for \(w - \frac{1}{2}\) and \(w + \frac{1}{2}\), respectively, by the method of Christoffel [3, Theorem 2.5], which gives the stated formulas.

Let \(L^2(\mathbb{R}, \Omega)\) be the \(L^2\) space on \(\Omega\) with the norm \(\| \cdot \|_{L^2(\mathbb{R}, \Omega)}\) defined by
\[
\|f\|_{L^2(\mathbb{R}, \Omega)}^2 := \langle f, f \rangle = \int_{-\infty}^{\infty} \left[ f(\sqrt{y^2 + 1}, y) \right]^2 \, w(y) \, dy.
\]
We consider the Fourier orthogonal expansions as defined in (2.1).

**Theorem 5.3.** Let \(f\) be a function defined on \(\Omega\). Define
\[
f_e(y) := \frac{f(\sqrt{y^2 + 1}, y) + f(-\sqrt{y^2 + 1}, y)}{2}
\]
and
\[
f_o(y) := \frac{f(\sqrt{y^2 + 1}, y) - f(-\sqrt{y^2 + 1}, y)}{2\sqrt{y^2 + 1}}.
\]
Then the partial sum operator for the Fourier series with respect to (5.4) satisfies (5.5)
\[
S_n f(x,y) = s_n(w; f_e, y) + x s_{n-1}(w; f_o, y).
\]
In particular, if \(s_n(w; f_e, x) \to f_e(x)\) and \(s_n(w; f_o, x) \to f_o(x)\) as \(n \to \infty\), then \(S_n f(x,y) \to f(x,y)\) as \(n \to \infty\). Furthermore, if \(f \in L^2(\Omega, w)\), then
\[
\|f - S_n(f)\|_{L^2(\mathbb{R}, \Omega)}^2 = \|s_{n-1}(w; f_e) - f_e\|_{L^2(w)}^2 + \|s_{n-1}(w; f_o) - f_o\|_{L^2(w)}^2.
\]
**Proof.** The proof is again similar to that of Theorem 3.2. We shall be brief. Since \(Y_{n,1}\) in (5.2) is independent of \(x\),
\[
\langle f, Y_{n,1} \rangle = \int_{-\infty}^{\infty} \left[ f(\sqrt{y^2 + 1}, y) + f(-\sqrt{y^2 + 1}, y) \right] p_n(w; y) w(y) \, dy = \langle f, p_n(w) \rangle_{L^2(w)}.
\]
Similarly, by the expression of \(Y_{n,2}\) in (5.2),
\[
\langle f, Y_{n,2} \rangle = \int_{-\infty}^{\infty} \left[ f(\sqrt{y^2 + 1}, y) - f(-\sqrt{y^2 + 1}, y) \right] p_{n-1}(w; y) \sqrt{y^2 + 1} w(y) \, dy
\]
\[= \int_0^{\infty} f_o(y) p_{n-1}(w; y) w_1(y) \, dy = \langle f_o, p_{n-1}(w_1) \rangle_{L^2(w_1)}.
\]
Consequently, by (5.3), we obtain
\[
\hat{f}_{n,1} = \frac{\langle f, p_n(w) \rangle_{L^2(w)}}{h_n(w)} = \hat{f}_{n}(w), \quad \hat{f}_{n,2} = \frac{\langle f, p_{n-1}(w_1) \rangle_{L^2(w_1)}}{h_{n-1}(w_1)} = \hat{f}_{n}(w),
\]
from which (5.4) follows. The rest of the proof follows as that of Theorem 3.2. \(\square\)

### 5.2. \(\Omega\) with one branch.
Here we consider only one brach of the hyperbola and we define
\[
\Omega = \{(x, y) : x^2 - y^2 = 1, \ x \geq 1\}.
\]
Comparing with (5.1), we can define the bilinear form on \(\Omega\) as
\[
\langle f, g \rangle := \int_{\mathbb{R}} f(\sqrt{y^2 + 1}, y) g(\sqrt{y^2 + 1}, y) w(y) \, dy.
\]
In order to construct an orthogonal basis, we parametrize the integral in the $x$ variable instead of the $y$ variable. A change of variable shows that
\[
\int_{-\infty}^{\infty} f(\sqrt{1+y^2}, y) dy = \int_{0}^{\infty} f(\sqrt{1+y^2}, -y) dy + \int_{0}^{\infty} f(\sqrt{1+y^2}, y) dy = \int_{1}^{\infty} \left[ f(x, -\sqrt{x^2-1}) dy + f(x, \sqrt{x^2-1}) \right] \frac{x}{\sqrt{x^2-1}} dx.
\]
Accordingly, for a weight function $w_0$ defined on $[1, \infty)$, we define the bilinear from
\[
(f, g) := \int_{1}^{\infty} \left[ f(x, \sqrt{x^2-1})g(x, \sqrt{x^2-1}) + f(x, -\sqrt{x^2-1})g(x, -\sqrt{x^2-1}) \right] w_0(x) dx.
\]

**Theorem 5.4.** Let $w_0$ be a weight function defined on $[1, \infty)$ and let $w_1(t) := (t^2 - 1)w_0(t)$. Then the polynomials
\[
Y_{n,1}(x, y) = p_n(w_0; x) \quad \text{and} \quad Y_{n,2}(x, y) = yp_{n-1}(w_1; x)
\]
form an orthogonal basis of $\mathcal{H}_n(\varpi)$ for $n \geq 1$. Furthermore,
\[
\langle Y_{n,1}, Y_{n,1} \rangle = 2h_n(w_0) \quad \text{and} \quad \langle Y_{n,2}, Y_{n,2} \rangle = 2h_{n-1}(w_1).
\]

**Proof.** For $n \geq 0$ and $m \geq 0$, we have
\[
\langle Y_{n,1}, Y_{m,1} \rangle = 2\int_{1}^{\infty} p_n(w_0; x)p_{m-1}(w_1; x) \left[ \sqrt{x^2-1} - \sqrt{x^2-1} \right] w_0(x) dx = 0.
\]
For $n, m \in \mathbb{N}_0$, we have
\[
\langle Y_{n,1}, Y_{m,1} \rangle = 2\int_{1}^{\infty} p_n(w_0; x)p_{m}(w_0; x)w_0(x) dx = 2h_n(w_0)\delta_{n,m}
\]
and
\[
\langle Y_{n,2}, Y_{m,2} \rangle = 2\int_{1}^{\infty} p_{n-1}(w_1; x)p_{m-1}(w_1; x)(x^2 - 1)w_0(x) dx = 2h_{n-1}(w_1)\delta_{n,m}
\]
since $w_1 = (\{\cdot\}^2 - 1)w_0$. This completes the proof. \hfill $\square$

**Corollary 5.5.** Let $w$ be an even weight function on $\mathbb{R}$ and let
\[
w_0(x) = \frac{xw(\sqrt{x^2-1})}{\sqrt{x^2-1}}, \quad x \geq 1.
\]
Then the polynomials in (5.8) form an orthogonal basis of $\mathcal{H}_n(\varpi)$ with respect to the inner product (5.6).

Let $L^2(\varpi, \Omega)$ be the $L^2$ space on $\Omega$ with the norm $\| \cdot \|_{L^2(\varpi, \Omega)}$ defined by
\[
\|f\|^2_{L^2(\varpi, \Omega)} := \langle f, f \rangle = \int_{1}^{\infty} \left[ \left| f(x, \sqrt{x^2-1}) \right|^2 + \left| f(x, -\sqrt{x^2-1}) \right|^2 \right] w_0(x) dx.
\]
We consider the Fourier orthogonal expansions as in (2.1).

**Theorem 5.6.** Let $f$ be a function defined on $\Omega$. Define
\[
f_c(x) := \frac{f(x, y) + f(x, -y)}{2} \quad \text{and} \quad f_o(y) := \frac{f(x, y) - f(x, -y)}{2y}, \quad y = \sqrt{x^2-1}.
\]
Then the partial sum operator for the Fourier series with respect to (5.7) satisfies
\[
S_n f(x, y) = s_n(w_0; f_c, x) + ys_{n-1}(w_1; f_o, x).
\]
In particular, if \( s_n(w_0; f_0, x) \rightarrow f_0(x) \) and \( s_n(w_1; f_0, x) \rightarrow f_0(x) \) as \( n \rightarrow \infty \), then 
\[ S_n f(x, y) \text{ converges to } f(x, y) \text{ as } n \rightarrow \infty. \]
Furthermore, if \( f \in L^2(\Omega, w) \), then
\[ \| f - S_n(f) \|_{L^2(\Omega, w)}^2 = \| s_{n-1}(w_0; f_0) - f_0 \|_{L^2(\Omega, w)}^2 + \| s_{n-1}(w_1; f_0) - f_0 \|_{L^2(\Omega, w)}^2. \]

The proof is similar to that of Theorem 5.3 and we skip it.

6. Two intersecting lines

Two intersecting lines can be transformed to the two coordinate axes by an affine transform. As a result, we consider \( \Omega = \{(x, y) : x = 0 \text{ or } y = 0\} \)
Let \( w_1 \) and \( w_2 \) be two weight functions defined on the real line. Define a bilinear form
\[ \langle f, g \rangle_{w_1, w_2} = \int f(x, 0)g(x, 0)w_1(x)dx + \int f(0, y)g(0, y)w_2(y)dy, \]
which is an inner product for \( \mathbb{R}[x, y]/(xy) \). We will make use of the results in \([9]\), which studies orthogonal polynomials on a wedge, defined as two line segments sharing a common end point. The standard wedge chosen in \([9]\) is
\[ \Omega_{\text{wd}} := \{(x, 1) : 0 \leq x \leq 1\} \cup \{(1, y) : 0 \leq y \leq 1\} \]
and the bilinear form there is defined as
\[ \langle f, g \rangle_{w_1, w_2}^{\text{wd}} = \int_0^1 f(x, 1)g(x, 1)w_1(x)dx + \int_0^1 f(1, y)g(1, y)w_2(y)dy. \]
A simple transform \((x, y) \mapsto (1 - x, 1 - y)\) shows that we could consider the wedge as \( \{(x, 0) : 0 \leq x \leq 1\} \cup \{(0, y) : 0 \leq y \leq 1\} \). The corresponding bilinear form is then a special case of (6.1) with respect to weight functions \( w_1(x)\chi_{[0,1]}(x) \) and \( w_2(x)\chi_{[0,1]}(x) \) defined on \( \mathbb{R} \). The finite integral domain can be considered as a consequence of the finite supports of \( w_1 \) and \( w_2 \). More generally, orthogonal polynomials on a wedge can be considered as a special case of orthogonal polynomials on two intersecting lines.

6.1. Orthogonal structure when \( w_1 = w_2 \). Let \( w \) be a weight function defined on \( \mathbb{R} \). We assume \( w_1 = w_2 = w \) and define
\[ \langle f, g \rangle := \int f(x, 0)g(x, 0)w(x)dx + \int f(0, y)g(0, y)w(y)dy, \]
In this case, the study in \([9]\) can be adopted with little change.

Theorem 6.1. Let \( w \) be a weight function on \( \mathbb{R} \) and let \( w_1(x) := x^2 w(x) \). Define
\[ Y_{n,1}(x, y) = p_n(w; x) + p_n(w; y) - p_n(w; 0), \quad n = 0, 1, 2, \ldots, \]
\[ Y_{n,2}(x, y) = xp_{n-1}(w_1; x) - yp_{n-1}(w_1; y), \quad n = 1, 2, \ldots. \]
Then \( \{Y_{n,1}, Y_{n,2}\} \) are two polynomials in \( \mathcal{H}_n(\mathbb{R}) \) and they are mutually orthogonal. Furthermore,
\[ \langle Y_{n,1}, Y_{n,1} \rangle = 2h_n(w_0) \quad \text{and} \quad \langle Y_{n,2}, Y_{n,2} \rangle = 2h_{n-1}(w_1). \]

The proof is identical to that of \([9]\) Theorem 2.2]. Furthermore, the Fourier orthogonal expansions on the wedge is studied in \([9]\), which can be entirely adopted to the current setting. Let \( L^2(\mathbb{R}, \Omega) \) be the \( L^2 \) space on \( \Omega \) with norm \( \| \cdot \|_{L^2(\mathbb{R}, \Omega)} \) defined by
\[ \| f \|_{L^2(\mathbb{R}, \Omega)}^2 = \int f(x, 0)^2 w(x)dx + \int f(0, y)^2 w(y)dy. \]
Theorem 6.2. Let \( f \) be a function defined on \( \Omega \). Define

\[
f_n(x) := \frac{f(x,0) + f(0,x)}{2} \quad \text{and} \quad f_o(x) := \frac{1}{2} \frac{f(x,0) - f(0,x)}{x}.
\]

Then

\[
S_n f(x,0) = s_n(w; f_c, x) + x s_{n-1}(w_1; f_o, x),
\]
\[
S_n f(0,y) = s_n(w; f_c, y) - y s_{n-1}(w_1; f_o, y).
\]

In particular, if \( s_n(w; f_c, x) \to f_c(x) \) and \( s_n(w_1; f_o, x) \to f_o(x) \) as \( n \to \infty \), then \( S_n f(x,y) \) converges to \( f(x,y) \) as \( n \to \infty \). Furthermore, if \( f \in L^2(\varpi, \Omega) \), then

\[
\|f - S_n(f)\|_{L^2(\varpi, \Omega)}^2 = 2 \left( \|s_{n-1}(w; f_c) - f_c\|_{L^2(w_0)}^2 + \|s_{n-1}(w_1; f_o) - f_o\|_{L^2(w_1)}^2 \right).
\]

This theorem is equivalent to \([9, Theorem 2.4]\) and its corollary.

As an example, we consider the case when \( w \) is the Gaussian \( w(x) = e^{-x^2} \). We shall need the Hermite polynomials \( H_n \) and the Laguerre polynomials \( L^\alpha_n \).

Proposition 6.3. For \( w(x) = e^{-x^2} \) the orthogonal polynomials of two variables in Theorem 6.1 are given by

\[
Y_{n,1}(x,y) = H_n(x) + H_n(y) - H_n(0), \quad n = 0, 1, 2, \ldots,
\]
\[
Y_{2n,2}(x,y) = x^2 H_{n-1}^2(x^2) - y^2 H_{n-1}^2(y^2), \quad n = 1, 2, \ldots,
\]
\[
Y_{2n+1,2}(x,y) = x L_n^\frac{1}{2}(x^2) - y L_n^\frac{1}{2}(y^2), \quad n = 0, 1, 2, \ldots.
\]

Proof. The Hermite polynomials \( H_n \) are orthogonal with respect to \( w(x) \), so \( Y_{n,1} \) is trivial. We need to find \( p_n(w_1) \) for \( w_1(x) = x^2 e^{-x^2} \) which we claim to be

\[
p_{2n}(w_1; x) = x^2 L_{n-1}^\frac{1}{2}(x^2) \quad \text{and} \quad p_{2n+1}(w_1; x) = x L_n^\frac{1}{2}(x^2).
\]

Indeed, the parity of these polynomials leads to the orthogonality of \( p_{2n}(w_1) \) and \( p_{2n+1}(w_1) \). Changing variable \( x^2 \to y \) shows that the orthogonality of \( p_{2n}(w_1) \) to even polynomials is equivalent to that of \( L_{n-1}^\frac{1}{2} \) and the orthogonality of \( p_{2n+1}(w_1) \) to odd polynomials is equivalent to that of \( L_n^\frac{1}{2} \).

6.2. Orthogonal structure on wedges and on intersection lines. In this subsection we show that orthogonal structure on two intersecting lines can be derived from orthogonal structure on a wedge, which works even if \( w_1 \neq w_2 \).

Let \( w_1 \) and \( w_2 \) be even functions on \( \mathbb{R} \), which we write as

\[
w_1(t) = u_1(t^2) \quad \text{and} \quad w_2(t) = u_2(t^2),
\]

so that the inner product \([6.1]\) becomes

\[
(f,g)_{w_1,w_2} = \int_{\mathbb{R}} f(x,0) g(x,0) u_1(x^2) dx + \int_{\mathbb{R}} f(0,y) g(0,y) u_2(y^2) dy.
\]

Let \( \mathcal{H}_n(\varpi) \) be the space of orthogonal polynomials of degree \( n \) with respect to this inner product. A basis in \( \mathcal{H}_n(\varpi) \) can be derived from orthogonal polynomials on the wedge with respect to the inner product

\[
(f,g)_{w_1,w_2}^{wdg} = \int_0^\infty f(x,0) g(x,0) u_1(x) dx + \int_0^\infty f(0,y) g(0,y) u_2(y) dy.
\]

We denote an orthogonal basis for \( \mathcal{H}_n(\varpi, u_2) \) by \( Y_{n,1}^{u_1,u_2} \) and \( Y_{n,2}^{u_1,u_2} \) to emphasize the dependence of the weight functions, as different weight functions will be used below.
Theorem 6.4. Let \( u_1 \) and \( u_2 \) be weight functions defined on \( \mathbb{R}_+ \). For \( i = 1, 2 \), define 
\[
\phi_{u_i}(t) = t^{-\frac{1}{2}} u_i(t) \quad \text{and} \quad \psi_{u_i}(t) = t^{\frac{1}{2}} u_i(t).
\]
For \( n = 1, 2, \ldots \), the polynomials 
\[
Y_{2n,1}(x, y) = Y_{n,1}^{\phi_{u_1},\phi_{u_2}}(x^2, y^2), \quad Y_{2n,2}(x, y) = Y_{n,2}^{\phi_{u_1},\phi_{u_2}}(x^2, y^2)
\]
(6.8) form an orthogonal basis for \( \mathcal{H}_{2n}(w_1, w_2) \) and the polynomials 
\[
Y_{2n+1,1}(x, y) = (x + y)Y_{n,1}^{\psi_{u_1},\psi_{u_2}}(x^2, y^2), \quad Y_{2n+1,2}(x, y) = (x + y)Y_{n,2}^{\psi_{u_1},\psi_{u_2}}(x^2, y^2).
\]
(6.9) form an orthogonal basis for \( \mathcal{H}_{2n+1}(w_1, w_2) \).

Proof. For \( i, j = 1, 2 \), changing variables \( s = x^2 \) and \( t = y^2 \) gives 
\[
\langle Y_{2n,i}, Y_{2m,j} \rangle_{w_1, w_2} = \int_0^{\infty} Y_{n,i}^{\phi_{u_1},\phi_{u_2}}(s, 0)Y_{m,j}^{\phi_{u_1},\phi_{u_2}}(s, 0) s^{-\frac{1}{2}} u_1(s) ds 
+ \int_0^{\infty} Y_{n,i}^{\phi_{u_1},\phi_{u_2}}(0, t)Y_{m,j}^{\phi_{u_1},\phi_{u_2}}(0, t) t^{-\frac{1}{2}} u_2(t) dt 
= \langle Y_{n,i}^{\phi_{u_1},\phi_{u_2}}, Y_{m,j}^{\phi_{u_1},\phi_{u_2}} \rangle_{w_1, w_2},
\]
which verifies the statement for even polynomials. Since \( Y_{2n+1,i}(x, 0) \) and \( Y_{2n+1,i}(0, y) \) are odd polynomials in \( x \) and in \( y \), respectively, the parity of the polynomials shows that \( \langle Y_{2n+1,i}, Y_{2m,j} \rangle_{w_1, w_2} = 0 \). Furthermore, for \( i = 1, 2 \), 
\[
\langle Y_{2n+1,i}, Y_{2m+1,j} \rangle_{w_1, w_2} = \int_{\mathbb{R}} x^2 Y_{n,i}^{\psi_{u_1},\psi_{u_2}}(x^2, 0)Y_{m,j}^{\psi_{u_1},\psi_{u_2}}(x^2, 0) u_1(x^2) dx 
+ \int_{\mathbb{R}} y^2 Y_{n,i}^{\psi_{u_1},\psi_{u_2}}(0, y^2)Y_{m,j}^{\psi_{u_1},\psi_{u_2}}(0, y^2) u_2(y^2) dy 
= \langle Y_{n,i}^{\psi_{u_1},\psi_{u_2}}, Y_{m,j}^{\psi_{u_1},\psi_{u_2}} \rangle_{w_1, w_2},
\]
where we have made the change of variables \( s = x^2 \) and \( t = y^2 \) again in the last step. This completes the proof. \( \square \)

Let \( L^2(\varpi, \Omega) \) be the \( L^2 \) space on \( \Omega \) with the norm \( \| \cdot \|_{L^2(\varpi, \Omega)} \) defined by 
\[
\| f \|^2_{L^2(\varpi, \Omega)} := \langle f, f \rangle = \int_1^{\infty} \left[ |f(x, \sqrt{x^2 - 1})|^2 + |f(x, -\sqrt{x^2 - 1})|^2 \right] w(x) dx.
\]
Furthermore, let \( L^2(u_1, u_2) \) be the \( L^2 \) space on the wedge \( \{ (x, 0) : x \geq 0 \} \cup \{ (0, y) : y \geq 0 \} \) with the norm \( \| \cdot \|_{L^2(u_1, u_2)} \) defined by 
\[
\| f \|^2_{w_1, w_2} := \int_0^{\infty} |f(x, 0)|^2 u_1(x) dx + \int_0^{\infty} |f(0, y)|^2 u_2(y) dy.
\]
Let \( s_{n}^{\psi_{u_1},\psi_{u_2}} f \) denote the \( n \)-th partial sum of the Fourier orthogonal expansions with respect to \( \{ \frac{\phi_{u_1},\phi_{u_2}}{\varpi, \varpi} \} \) on the wedge.

Theorem 6.5. Let \( f \) be a function defined on \( \Omega \). Define 
\[
f_e(x, y) := \frac{f(x, y) + f(-x, -y)}{2} \quad \text{and} \quad f_o(x, y) := \frac{f(x, y) - f(-x, -y)}{2(x + y)}.
\]
Furthermore, let \( \Phi(x, y) := (\sqrt{x}, \sqrt{y}) \). Then the partial sum operator for the Fourier orthogonal series with respect to \( \{ \frac{\phi_{u_1},\phi_{u_2}}{\varpi, \varpi} \} \) satisfies 
\[
S_n f(x, y) = s_{\frac{n}{2}}^{\psi_{u_1},\psi_{u_2}}(f_e \circ \Phi)(x^2, y^2) + (x + y)s_{\frac{n}{2}}^{\psi_{u_1},\psi_{u_2}}(f_o \circ \Phi)(x^2, y^2).
\]
Furthermore, if \( f \in L^2(w_1, w_2, \Omega) \), then
\[
\| f - S_n(f) \|_{L^2(w_1, w_2, \Omega)}^2 = \| s_{\frac{\alpha_1}{2}, \frac{\phi_1}{2}} f_e - f_e \|_{L^2(\phi_1, \phi_2)}^2 + \| s_{\frac{\psi_1}{2}, \frac{\psi_2}{2}} f_o - f_o \|_{L^2(\psi_1, \psi_2)}^2.
\]

**Proof.** Following the proof of the previous theorem, we see that
\[
\langle f, Y_{2n,j}(w_1, w_2) \rangle = \int_{0}^{\infty} [f(x, 0) + f(-x, 0)] Y_{n,j}^{\phi_1, \phi_2}(x^2, 0) u_1(x^2) dx
\]
\[
+ \int_{0}^{\infty} [f(0, y) + f(0, -y)] Y_{n,j}^{\phi_1, \phi_2}(0, y^2) u_2(y^2) dy
\]
\[
= \int_{0}^{\infty} (f_e \circ \Phi)(s, 0) Y_{n,j}^{\phi_1, \phi_2}(s, 0) s^{-\frac{1}{2}} u_1(s) ds
\]
\[
+ \int_{0}^{\infty} (f_o \circ \Phi)(0, t) Y_{n,j}^{\phi_1, \phi_2}(0, t) t^{-\frac{1}{2}} u_2(t) dt
\]
\[
= \langle f_e \circ \Phi, Y_{n,i}^{\phi_1, \phi_2} \rangle_{\phi_1, \phi_2} \text{wdg}.
\]

Similarly, we can verify that
\[
\langle f, Y_{2n+1,i}(w_1, w_2) \rangle = \langle f_o \circ \Phi, Y_{n,i}^{\psi_1, \psi_2} \rangle_{\psi_1, \psi_2} \text{wdg},
\]
since \((f_o \Phi)(x^2, 0) = (f(x, 0) - f(-x, 0))/(2x)\) and \((f_e \Phi)(0, y^2) = (f(0, y) - f(0, -y))/(2y)\). In particular, together with the identities in the proof of the previous theorem, we obtain
\[
\hat{f}_{2n,i} = \int_{0}^{\infty} Y_{n,j}^{\phi_1, \phi_2}(s, 0) s^{-\frac{1}{2}} u_1(s) ds \quad \text{and} \quad \hat{f}_{2n+1,i} = \int_{0}^{\infty} Y_{n,j}^{\phi_1, \phi_2}(0, t) t^{-\frac{1}{2}} u_2(t) dt,
\]
where the righthand sides are the Fourier coefficients with respect to the basis \(Y_{n,i}^{\phi_1, \phi_2}\) and \(Y_{n,i}^{\psi_1, \psi_2}\) on the wedge, respectively. The relation on the partial sums then follows from (6.8) and (6.9). \(\square\)

### 6.3. Orthogonal structure for Jacobi weight functions

In this example, we consider the example when both \(w_1\) and \(w_2\) are Jacobi weight functions with support sets on \([0, 1]\). In other words, we consider
\[
w_1(t) = |t|^{2\alpha}(1 - t^2)^{\alpha} \chi_{[0,1]}(t), \quad w_2(t) = |t|^{2\beta}(1 - t^2)^{\beta} \chi_{[0,1]}(t).
\]

For \(\alpha, \beta, \gamma > -1\), we renormalize the the inner product (6.7) on the wedge as
\[
\langle f, g \rangle_{\alpha, \beta, \gamma} := c_{\alpha, \gamma} \int_{0}^{1} f(x, 0) g(x, 0) |x|^{2\gamma}(1 - x^2)^{\alpha} dx
\]
\[
+ c_{\beta, \gamma} \int_{0}^{1} f(0, y) g(0, y) |y|^{2\gamma}(1 - y^2)^{\beta} dy,
\]
where
\[
c_{\alpha, \gamma} := \left( \int_{-1}^{1} t^{2\gamma}(1 - t^2)^{\alpha} dt \right)^{-1} = \frac{\Gamma(\gamma + \alpha + \frac{3}{2})}{\Gamma(\gamma + \frac{1}{2}) \Gamma(\alpha + 1)}.
\]
Orthogonal polynomials with respect to this inner product can be derived from [9] Theorem 3.2] by making a change of variables \((x, y) \mapsto (1 - x, 1 - y)\). The result is as follows:
Theorem 6.6. Let \( Y_{0,1}(x,y) = 1, Y_{1,1}(x,y) = x \) and \( Y_{1,2}(x,y) = y \). For \( n = 1, 2, \ldots \), let
\[
Y_{2n,1}(x,y) = P_n^{(\gamma - \frac{1}{2}, \alpha)}(x^2) + P_n^{(\gamma - \frac{3}{2}, \beta)}(y^2) - \left( \frac{n + \gamma - \frac{1}{2}}{n} \right),
\]
\[
Y_{2n,2}(x,y) = \frac{(\gamma + \alpha + \frac{3}{2})n}{(\alpha + 1)_{n-1}} x P_{n-1}^{(\gamma + \frac{1}{2}, \alpha)}(x^2) - \frac{(\gamma + \beta + \frac{3}{2})n}{(\beta + 1)_{n-1}} y P_{n-1}^{(\gamma + \frac{3}{2}, \beta)}(y^2),
\]
and
\[
Y_{2n+1,1}(x,y) = (x + y) \left[ P_n^{(\gamma + \frac{1}{2}, \alpha)}(x^2) + P_n^{(\gamma + \frac{3}{2}, \beta)}(y^2) - \left( \frac{n + \gamma + \frac{1}{2}}{n} \right) \right],
\]
\[
Y_{2n+1,2}(x,y) = (x + y) \left[ \frac{\gamma + \alpha + 1}{n} x P_{n-1}^{(\gamma + \frac{3}{2}, \alpha)}(x^2) - \frac{\gamma + \beta + 1}{n+1} y P_{n-1}^{(\gamma + \frac{3}{2}, \beta)}(y^2) \right].
\]
Then \( Y_{n,1}, Y_{n,2} \) form a basis in \( \mathcal{H}_n(w_1, w_2) \) and
\[
\langle Y_{2n,1}, Y_{2n,2} \rangle_{\alpha, \beta, \gamma} = \frac{(\beta - \alpha)(\gamma + 1)n+1}{(2n + \gamma + \alpha + \frac{3}{2})(2n + \gamma + \beta + \frac{3}{2})(n-1)!},
\]
\[
\langle Y_{2n+1,1}, Y_{2n+1,2} \rangle_{\alpha, \beta, \gamma} = \frac{(\beta - \alpha)(\gamma + 1)n+2}{(2n + \gamma + \alpha + \frac{3}{2})(2n + \gamma + \beta + \frac{3}{2})(n-1)!}.
\]

Proof. With our notation \( w_1(t) = u_1(t^2) \) and \( w_2(t) = u_2(t^2) \), we have
\[
u_1(t) = t^\gamma (1 - t)\alpha, \quad u_2(t) = t^\gamma (1 - t)\beta, \quad t \in [0, 1].
\]

With these weight functions, we renormalize the inner product \( \langle 6.7 \rangle \) as
\[
\langle f, g \rangle_{w_{\gamma}} := c_{\alpha, \beta, \gamma} \int_0^1 f(x,0)g(x,0)x^\gamma(1-x)^\alpha dx + c'_{\beta, \gamma} \int_0^1 f(0,y)g(0,y)y^\gamma(1-y)^\beta dy,
\]
where \( c_{\alpha, \gamma} = c_{\alpha, \gamma + \frac{1}{2}} \) is the normalization constant of \( t^\gamma (1 - t)\alpha \). Orthogonal polynomials for this inner product \( \langle 6.7 \rangle \) on the wedge \( \{(x,0) : 0 \leq x \leq 1\} \cup \{(0,y) : 0 \leq y \leq 1\} \) are given in [9] Theorem 3.2), up to a simple change of variables \( (x,y) \mapsto (1 - x, -y) \), since the wedge considered in [11] is \( \{(x,1) : 0 \leq x \leq 1\} \cup \{(1,y) : 0 \leq y \leq 1\} \).

Since \( \psi u_1(t) = t^{\gamma - \frac{1}{2}}(1 - t)^\alpha \) and \( \psi u_2(t) = t^{\gamma + \frac{1}{2}}(1 - t)^\beta \), we then obtain orthogonal polynomials \( Y_{n,1,\psi u_1,\psi u_2} \) from the results in [9] by considering \( \gamma \mapsto \gamma - \frac{1}{2} \), which gives the formula \( Y_{2n,i} \) by Theorem 6.6 where we have used the fact that \( c_{\alpha, \gamma} = c_{\alpha, \gamma - \frac{1}{2}} \) so that
\[
\langle 1, 1 \rangle_{\alpha, \beta, \gamma} = (1, 1)_{w_{\gamma}} \text{ holds. Furthermore, since } \psi u_1(t) = t^{\gamma + \frac{1}{2}}(1 - t)^\alpha \text{ and } \psi u_2(t) = t^{\gamma + \frac{1}{2}}(1 - t)^\beta, \text{ we obtain orthogonal polynomials } Y_{n,1,\psi u_1,\psi u_2} \text{ from the results in [9] by considering } \gamma \mapsto \gamma + \frac{1}{2}. \text{ In this case, however, a shift in the index is necessary because of the normalization of the constants. Indeed, in order to reduce the orthogonality of } Y_{2n+1,2} \text{ with respect to } \langle \cdot, \cdot \rangle_{\alpha, \beta, \gamma} \text{ from the orthogonality with respect to } \langle \cdot, \cdot \rangle_{w_{\gamma}}, \text{ we have incorporated the constant}
\]
\[
\frac{c_{\alpha, \gamma}}{c_{\alpha, \gamma + 1}} = \frac{c'_{\alpha, \gamma + \frac{1}{2}}}{c'_{\alpha, \gamma + \frac{1}{2}}} = \frac{\gamma + 1}{\gamma + \alpha + \frac{3}{2}}
\]
in the constant in front of \( x P_{n-1}^{(\gamma + \frac{3}{2}, \alpha)}(x^2) \) in its expression, and the similar change is made on the second term of its expression. □
The convergence of the Fourier orthogonal expansions with respect to the Jacobi weight functions in $L^2(u_1,u_2)$ on the wedge is established in [9] Theorem 3.4, from which we can derive the convergence of the Fourier orthogonal expansions for the Jacobi weight functions in $L^2(w_1,w_2,\Omega)$ from that Theorem 6.5 The derivation is straightforward but the statement is somewhat complicated. We leave it to interested readers.

As another example, we can consider the case when $w_1$ and $w_2$ are Laguerre weights,

$$w_1(x) = x^\alpha e^{-x} \chi_{[0,\infty)}(x) \quad \text{and} \quad w_2(x) = x^\beta e^{-x} \chi_{[0,\infty)}(x), \quad \alpha, \beta > -1.$$ 

This can be developed similarly as in the Jacobi case.

7. Two parallel lines

Two parallel lines can be transformed to the lines $y = 1$ and $y = -1$ by an affine transform. We then consider

$$\Omega = \{(x,y) : y = 1 \text{ and } y = -1\}$$

Let $w$ be a weight functions defined on the real line. Define a bilinear form

$$(7.1) \quad \langle f, g \rangle_w = \int_{\mathbb{R}} [f(x,-1)g(x,-1) + f(x,1)g(x,1)] w(x) dx,$$

which is an inner product for $\mathbb{R}[x,y]/(y^2 - 1)$.

**Theorem 7.1.** Let $w$ be a weight function on $\mathbb{R}$ and let $w_1(x) := x^2w(x)$. Define

$$Y_{n,1}(x,y) = p_n(w_1;x), \quad n = 0,1,2,\ldots,$$

$$Y_{n,2}(x,y) = yp_{n-1}(w_1;x), \quad n = 1,2,\ldots.$$ 

Then $\{Y_{n,1}, Y_{n,2}\}$ are two polynomials in $H_n(\varpi)$ and they are mutually orthogonal.

**Proof.** It is evident that $\langle Y_{n,1}, Y_{n,2}\rangle = 0$ since there is only one $y$. Furthermore, $\langle Y_{n,1}, Y_{m,1}\rangle = 2h_n(w_0)\delta_{n,m}$ and $\langle Y_{n,2}, Y_{m,2}\rangle = 2h_{n-1}(w_0)\delta_{n,m}$ by the orthogonality of $p_n(w_0)$. \[\square\]

For the Hermite and Laguerre weights, we note that the resulting orthogonal polynomials are eigenfunctions of simple partial differential operators.

**Proposition 7.2.** For the Hermite weight function $w(x) = e^{-x^2}$, the orthogonal polynomials in (7.2) are the eigenfunctions of a second order differential operator; more precisely, the polynomials $H_n(x)$ and $yH_{n-1}(x)$ satisfy the equation

$$(7.3) \quad Lu := \partial_{xx}u - 2x\partial_xu - 2y\partial_yu = -2nu.$$ 

**Proof.** The Hermite polynomial $v = H_n$ satisfies the equation

$$v'' - 2xv' = -2nu.$$ 

The verification of (7.3) for $u(x,y) = H_n(x)$ follows immediately since $\partial_yu = 0$ and also for $u(x,y) = yH_{n-1}(x)$ since $y\partial_yu = u$. \[\square\]

**Proposition 7.3.** For the Laguerre weight function $w(x) = e^{-x}$, the orthogonal polynomials in (7.2) are the eigenfunctions of a second order differential operator; more precisely, the polynomials $L_n^\alpha(x)$ and $yL_{n-1}^\alpha(x)$ satisfy the equation

$$(7.4) \quad Lu := \partial_{xx}u + (\alpha + 1 - x)\partial_xu - y\partial_yu = -nu.$$ 

**Proof.** The verification follows as the previous proposition, using the fact that the Laguerre polynomial $v = L_n^\alpha$ satisfies the equation $v'' + (\alpha + 1 - y)v' = -ny$. \[\square\]
8. Interpolation

Consider the problem of interpolating a function \( f(x, y) \) using any of the families of orthogonal polynomials constructed above, which we denote as \( Y_{n,1}(x, y) \) and \( Y_{n,2}(x, y) \), and without loss of generality we for now assume our geometry is invariant under reflection across the \( x \) axis, so that if \((x, y) \in \Omega \) then so is \((x, -y)\) (e.g., the one-branch Hyperbola or the circle). Given a set of \( 2n \) interpolation points \( \{ (x_j, \pm y_j) \}_{j=1}^n \), consider the problem of finding coefficients \( f_{k,1}^n \) for \( k = 0, \ldots, n - 1 \) and \( f_{k,2}^n \) for \( k = 1, \ldots, n \), so that the polynomial

\[
(8.5) \quad f_n(x, y) = f_{0,1}^n Y_{0,1}(x, y) + \sum_{k=1}^{n-1} \left[ Y_{k,1}(x, y)f_{k,1}^n + Y_{k,2}(x, y)f_{k,2}^n \right] + f_{n,2}^n Y_{n,2}(x, y)
\]

interpolates \( f(x, y) \) at \( x_j, \pm y_j \):

\[
f_n(x_j, \pm y_j) = f(x_j, \pm y_j).
\]

A straightforward method to determine the coefficients in (8.5) is to solve a linear system:

\[
V \begin{pmatrix} f_{0,1}^n \\ f_{1,1}^n \\ \vdots \\ f_{n-1,1}^n \\ f_{n,1}^n \\ f_{1,2}^n \\ \vdots \\ f_{n-1,2}^n \\ f_{n,2}^n \end{pmatrix} = \begin{pmatrix} f(x_1, y_1) \\ \vdots \\ f(x_n, y_n) \\ f(x_1, -y_1) \\ \vdots \\ f(x_n, -y_n) \end{pmatrix}
\]

where \( V \) is the \( 2n \times 2n \) interpolation matrix

\[
V = \begin{pmatrix} Y_{0,1}(x_1, y_1) & \cdots & Y_{n-1,1}(x_1, y_1) & Y_{n,2}(x_1, y_1) \\ \vdots & \ddots & \vdots & \vdots \\ Y_{0,1}(x_n, y_n) & \cdots & Y_{n-1,1}(x_n, y_n) & Y_{n,2}(x_n, y_n) \\ Y_{0,1}(x_1, -y_1) & \cdots & Y_{n-1,1}(x_1, -y_1) & Y_{n,2}(x_1, -y_1) \\ \vdots & \ddots & \vdots & \vdots \\ Y_{0,1}(x_n, -y_n) & \cdots & Y_{n-1,1}(x_n, -y_n) & Y_{n,2}(x_n, -y_n) \end{pmatrix}.
\]

However, solving this system requires \( O(n^3) \) operation for \( n \) interpolation points, we have no guarantees the system is invertible, and it is not immediately amenable to analysis.

In this section we give two alternative constructions of the interpolation polynomial. The first construction is based on interpolation polynomials of one variable, which works for general interpolation grids and allows us to relate one-dimensional interpolation results to this higher dimensional setting. The second construction is based on Gaussian quadrature rules which allows efficient construction of interpolants at specific grids generated from Gaussian quadrature.

---

1The choice of having the term \( Y_{n,2} \) as opposed to \( Y_{n,1} \) is in some sense arbitrary, but may be required depending on the choice of grids. We have made this choice for concreteness in the discussion. Further, it is also possible to have an odd number of points, in which case we would need neither extra term.
8.1. Interpolation on quadratic curves. In this subsection we show that interpolation polynomials on a quadratic curve can be expressed via interpolation polynomials of one variable, in a way that lets us bootstrap one variable results to this setting.

First we recall classical results on the real line. Let \( w \) be a weight function on \( \mathbb{R} \). Let \( p_k(w) \) be the \( k \)-th orthogonal polynomial with respect to \( w \). Let \( \{ t_j : 1 \leq j \leq n \} \) be the set of zeros of \( p_n(w) \). The unique Lagrange interpolation polynomial of degree \( n - 1 \) based on these zeros is given by

\[
L_n(w; f, t) = \sum_{k=1}^{n} f(t_j) \ell_{j,n}(t), \quad \ell_{j,n}(t) = \frac{p_n(w; t)}{p_n'(w; t_j)(t - t_j)}.
\]

Let \( K_n(w; \cdot, \cdot) \) denote the reproducing kernel

\[
K_n(w; x, y) = \sum_{k=0}^{n} \frac{p_k(w; x)p_k(w; y)}{h_k(w)}, \quad h_k(w) = \int_{\mathbb{R}} |p_k(w)|^2 w(x) dx
\]

of the space of polynomials of degree at most \( n \). By the Christoffel–Darboux formula, the fundamental interpolation polynomial \( \ell_{j,n} \) is also equal to

\[
\ell_{j,n}(t) = \frac{K_n(w; t_j, x)}{K_n(w; t_j, t_j)} = \lambda_{j,n} K_n(w; t_j, x),
\]

where \( \lambda_{j,n} = [K_{n-1}(w; t_j, x)]^{-1} \) are the weights of the Gaussian quadrature rule. By the reproducing property of \( K_{n-1} \) and the Christoffel–Darboux formula, it is easy to see that

\[
(8.6) \quad \int_{-1}^{1} \ell_{j,n}(t) \ell_{k,n}(t) w(t) dt = \lambda_{j,n} \delta_{j,k}.
\]

We now consider interpolation polynomial \( \mathcal{L}_{2n} f \) on the circle, as defined in Propositions 8.9 and 8.10. As we have shown, \( \mathcal{L}_{2n} f(x, y) \) is the unique polynomial in the space

\[
\mathcal{P}_n := \text{span}\{Y_{k,1} : 0 \leq k \leq n - 1\} \cup \{Y_{k,2} : 1 \leq k \leq n\} = \Pi_{n-1}^{(2)} \oplus y \Pi_{n-1}^{(2)},
\]

that interpolates \( f \) at \((x_j, y_j)\) and \((x_j, -y_j)\), \(1 \leq j \leq n\), where \( x_j, 1 \leq j \leq n \) are zeros of the orthogonal polynomial \( p_n(w_{-\frac{1}{2}}) \) on \([-1, 1]\), \( y_j = \sqrt{1 - x_j^2} \) and the superscript \((x)\) in \( \Pi_{n-1}^{(x)} \) indicates that it is a space of polynomials in \( x \) variable. It turns out that \( \mathcal{L}_{2n} f \) admits a simple expression in terms of interpolation polynomials of one variable.

**Proposition 8.1** (Circle). Let \( w_{-\frac{1}{2}} \) be defined on \([-1, 1]\) as in Theorem 3.1. Define \( f_c \) and \( f_o \) as in Theorem 3.2. Then the interpolation polynomial \( \mathcal{L}_{2n} f \) can be written as

\[
(8.7) \quad \mathcal{L}_{2n} f(x, y) = L_n\left(w_{-\frac{1}{2}}; f_c, x\right) + yL_n\left(w_{-\frac{1}{2}}; f_o, x\right).
\]

**Proof.** By its definition, \( \ell_j(x) \in \Pi_{n-1}(x) \), so that \( \ell_j \in \mathcal{P}_n \) and \( y\ell_j \in \mathcal{P}_n \). Hence, \( L_n \) is an element of \( \mathcal{P}_n \). Furthermore,

\[
\mathcal{L}_n f(x_j, y_j) = f_c(x_j)\ell_j(x_j) + y_j f_o(x_j)\ell_j(x_j) = f(x_j, y_j)
\]

and

\[
\mathcal{L}_n f(x_j, -y_j) = f_c(x_j)\ell_j(x_j) - y_j f_o(x_j)\ell_j(x_j) = f(x_j, -y_j)
\]

for \( 1 \leq j \leq n \). Hence, the interpolation conditions are satisfied. \qed
Proof. We write

In particular, if both \( P \) and \( g \) are defined on \([-1,1]\), let the error of best approximation by polynomials of degree at most \( m \) be denoted by

\[
E_m(g) = \inf_{p_m \in \Pi_m} \| g - p_m \|_{\infty}.
\]

Theorem 8.2. Let \( f(x,y) \) be a function defined on the unit circle. Then

\[
\| L_n f \|_{L^2(\mathbb{R},\Omega)} \leq \max_{1 \leq j \leq n} |f(x_j)| + \max_{1 \leq j \leq n} |f_o(x_j)|.
\]

In particular, if both \( f_e \) and \( f_o \) are continuous, then \( \| L_n f - f \|_{L^2(w)} \to 0 \). Moreover,

\[
\| L_n f - f \|_{L^2(\mathbb{R},\Omega)} \leq 2E_{n-1}(f_e) + 2E_{n-1}(f_o).
\]

Proof. We write \( L_n f(x) = L_n \left( w_{-\frac{1}{2}} f, x \right) \) in this proof. By the orthogonality of \( \Pi_{n-1}^{(x)} \) and \( y \Pi_{n-1}^{(y)} \), we obtain

\[
\| L_n f \|_{L^2(\mathbb{R},\Omega)} = c_w \int_{-\pi}^{\pi} |L_n f(\cos \theta, \sin \theta)|^2 w(\cos \theta) d\theta
\]

\[
= 2c_w \int_{-1}^{1} |L_n f_e(t)|^2 w_{-\frac{1}{2}}(t) dt + 2c_w \int_{-1}^{1} |L_n f_o(t)|^2 (1 - t^2) w_{-\frac{1}{2}}(t) dt.
\]

A classical result derived using [8,6] shows that

\[
2c_w \int_{-1}^{1} \left| L_n \left( w_{-\frac{1}{2}} f_e, x \right) \right|^2 w_{-\frac{1}{2}}(t) dt = \sum_{j=1}^{n} \lambda_{j,n} |f_e(x_j)|^2 \leq \max_{1 \leq j \leq n} |f_e(x_j)|^2,
\]

and

\[
2c_w \int_{-1}^{1} |L_n f_o(t)|^2 (1 - t^2) w_{-\frac{1}{2}}(t) dt + 2c_w \int_{-1}^{1} |L_n f_o(t)|^2 w_{-\frac{1}{2}}(t) dt \leq \max_{1 \leq j \leq n} |f_o(x_j)|^2.
\]

To prove the convergence, we use the fact that \( L_n f = f \) if \( f \in \mathcal{P}_n \). Hence, for \( P(x,y) = q_1(x) + q_2(y) \) with \( q_1, q_2 \in \Pi_{n-1} \), we obtain from \( f(x,y) = f_e(x) + y f_o(x) \) that

\[
\| f - P \|_{L^2(\mathbb{R},\Omega)} \leq \| f_e - q_1 \|_{L^2(w)} + \| q_2 \|_{L^2(w)} \leq \| f_e - q_1 \|_{\infty} + \| f_o - q_2 \|_{\infty},
\]

so that

\[
\| L_n f - f \|_{L^2(\mathbb{R},\Omega)} = \| L(f - P_n) \|_{L^2(w)} \leq \| L(f - P_n) \|_{L^2(w)} + \| f - P_n \|_{L^2(w)} \leq 2\| f_e - q_1 \|_{\infty} + 2\| f_o - q_2 \|_{\infty}.
\]

Taking infimum over \( q_1 \) and \( q_2 \), respectively, we conclude that

\[
\| L_n f - f \|_{L^2(\mathbb{R},\Omega)} \leq 2E_{n-1}(f_e) + 2E_{n-1}(f_o),
\]

which clearly goes to zero as \( n \to \infty \). \( \square \)

A similar construction readily translates to each of the other quadratic curves. The cases of intersection lines and parallel lines are more or less trivial, so we state the results only for non-degenerate quadratic curves. Since the proofs are essentially the same as the circle case, we shall omit them.
Let \( \Omega = \{(x, y) : y = x^2, \ x \in \mathbb{R}\} \) be the parabola. Let \( \mathcal{L}_n f \) be the interpolation polynomial defined in Proposition 8.9 and Corollary 8.11. It is the unique polynomial in the space
\[
\mathcal{P}_n := \text{span}\{Y_{k,1} : 0 \leq k \leq n - 1\} \cup \{Y_{k,2} : 1 \leq k \leq n\} = \Pi_{n-1}^{(y)} \cup x\Pi_n^{(y)},
\]
see Theorem 4.4 that interpolates \( f \) at \((x_j, y_j)\) and \((-x_j, y_j)\), \(1 \leq j \leq n\), where \( y_j, 1 \leq j \leq n\) are zeros of \( p_n(w_{-\frac{1}{4}}) \) on \( \mathbb{R}_+ \) and \( x_j = \sqrt{y_j} \).

**Proposition 8.3** (Parabola). Let \( f \) be defined on \( \Omega \). Define \( f_e(y) \) and \( f_o(y) \) as in Theorem 4.4. Then the interpolation polynomial \( \mathcal{L}_n f \) can be written as
\[
(8.8) \quad \mathcal{L}_n f(x, y) = L_n \left( w_{-\frac{1}{4}}; f_e, y \right) + xL_n \left( w_{-\frac{1}{4}}; f_o, y \right).
\]

**Theorem 8.4.** Let \( f \) be a function defined on the parabola \( \Omega \). Then
\[
\|\mathcal{L}_n f\|_{L^2(\mathbb{R}^2, \omega)} \leq \max_{1 \leq j \leq n} |f_e(y_j)| + M \max_{1 \leq j \leq n} |f_o(y_j)|,
\]
if \( w \) is supported at \([0, M]\) for some \( M > 0 \). In particular, if \( f_e \) and \( f_o \) are continuous, then \( \|\mathcal{L}_n f - f\|_{L^2(\mathbb{R}^2, \omega)} \to 0 \).

Let \( \Omega = \{(x, y) : x^2 - y^2 = 1, \ y \in \mathbb{R}\} \) be the hyperbola of two branches. Let \( \mathcal{L}_{2n} f \) be the interpolation polynomial defined in Proposition 8.9 and Corollary 8.12. It is the unique polynomial in the space
\[
\mathcal{P}_n := \text{span}\{Y_{k,1} : 0 \leq k \leq n - 1\} \cup \{Y_{k,2} : 1 \leq k \leq n\} = \Pi_{n-1}^{(y)} \cup x\Pi_n^{(y)},
\]
see Theorem 5.4 that interpolates \( f \) at \((x_j, y_j)\) and \((-x_j, -y_j)\), \(1 \leq j \leq n\), where \( y_j, 1 \leq j \leq n\) are zeros of \( p_n(w) \) and \( x_j = \sqrt{y_j^2 + 1} \).

**Proposition 8.5** (Hyperbola, two branches). Let \( f \) be defined on the hyperbola \( \Omega \). Define \( f_e(y) \) and \( f_o(y) \) as in Theorem 5.3. Then the interpolation polynomial \( \mathcal{L}_{2n} f \) can be written as
\[
(8.9) \quad \mathcal{L}_{2n} f(x, y) = L_n (w; f_e, y) + xL_n (w; f_o, y).
\]

**Theorem 8.6.** Let \( f \) be defined on the hyperbola \( \Omega \) of two branches. Then
\[
\|\mathcal{L}_n f\|_{L^2(\mathbb{R}^2, \omega)} \leq \max_{1 \leq j \leq n} |f_e(y_j)| + M^2 \max_{1 \leq j \leq n} |f_o(y_j)|,
\]
if \( w \) is supported on \([-M, M]\) for some \( M > 0 \). In particular, if both \( f_e \) and \( f_o \) are continuous, then \( \|\mathcal{L}_n f - f\|_{L^2(\mathbb{R}^2, \omega)} \to 0 \).

Let \( \Omega = \{(x, y) : x^2 - y^2 = 1, \ x \geq 1\} \) be the hyperbola of one branch. Let \( \mathcal{L}_{2n} f \) be the interpolation polynomial defined in Proposition 8.9 and Corollary 8.13. It is the unique polynomial in the space
\[
\mathcal{P}_n := \text{span}\{Y_{k,1} : 0 \leq k \leq n - 1\} \cup \{Y_{k,2} : 1 \leq k \leq n\} = \Pi_{n-1}^{(x)} \cup y\Pi_n^{(x)},
\]
see Theorem 5.4 that interpolates \( f \) at \((x_j, y_j)\) and \((-x_j, -y_j)\), \(1 \leq j \leq n\), where \( x_j, 1 \leq j \leq n\) are zeros of \( p_n(w_o) \) and \( y_j = \sqrt{x_j^2 + 1} \).

**Proposition 8.7** (Hyperbola, one branch). Let \( f \) be defined on the hyperbola \( \Omega \). Define \( f_e(y) \) and \( f_o(y) \) as in Theorem 5.6. Then the interpolation polynomial \( \mathcal{L}_{2n} f \) can be written as
\[
(8.10) \quad \mathcal{L}_{2n} f(x, y) = L_n (w_0; f_e, x) + yL_n (w; f_o, x).
\]
Theorem 8.8. Let $f$ be defined on the hyperbola $\Omega$ of one branch. Then
\[
\|L_n f\|_{L^2(\varpi, \Omega)} \leq \max_{1 \leq j \leq n} |f_e(x_j)| + M^2 \max_{1 \leq j \leq n} |f_o(x_j)|,
\]
if $w_0$ is supported on $[1, M]$ for some $M > 0$. In particular, if $f_e$ and $f_o$ are continuous, then $\|L_n f - f\|_{L^2(\varpi, \Omega)} \to 0$.

8.2. Interpolation via quadrature. We will now determine these coefficients via a quadrature rule that preserves orthogonality. This construction enables the calculation of interpolation coefficients in $O(n^2)$ complexity. We begin with a general proposition that relates quadrature rules to interpolation. Below, $\phi_n$ will be a carefully chosen ordering of $Y_{n,1}$ and $Y_{n,2}$, chosen to ensure orthogonality is preserved and $M = 2n$.

Proposition 8.9. Suppose we have a discrete inner product for a basis $\{\phi_j\}_{j=0}^{M-1}$ of the form
\[
\langle f, g \rangle_M = \sum_{j=1}^{M} w_j f(x_j, y_j) g(x_j, y_j)
\]
satisfying $\langle \phi_m, \phi_n \rangle_M = 0$ for $m \neq n$ and $\langle \phi_n, \phi_n \rangle_M \neq 0$. Then the function
\[
L_M f(x, y) = \sum_{n=0}^{M-1} f^M_n \phi_n(x, y)
\]
interpolates $f(x, y)$ at $(x_j, y_j)$, where $f^M_n := \frac{\langle \phi_n, f \rangle_M}{\langle \phi_n, \phi_n \rangle_M}$.

Proof. Define the evaluation matrix
\[
E = \begin{pmatrix}
\phi_0(x_1, y_1) & \cdots & \phi_{M-1}(x_1, y_1) \\
\vdots & \ddots & \vdots \\
\phi_0(x_M, y_M) & \cdots & \phi_{M-1}(x_M, y_M)
\end{pmatrix}
\]
The definition of $f^M_n$ can be written in matrix form
\[
P \begin{pmatrix} f(x_1) \\ \vdots \\ f(x_M) \end{pmatrix} = \begin{pmatrix} f^M_0 \\ \vdots \\ f^M_{M-1} \end{pmatrix}
\]
where $P = N^{-1} E^T W$ for
\[
N = \begin{pmatrix}
(\sum_{j=1}^{M} w_j \phi_0(x_j)^2) & \cdots & \sum_{j=1}^{M} w_j \phi_{M-1}(x_j)^2 \\
\vdots & \ddots & \vdots \\
\sum_{j=1}^{M} w_j \phi_0(x_j)^2 & \cdots & (\sum_{j=1}^{M} w_j \phi_{M-1}(x_j)^2)
\end{pmatrix}, \quad W = \begin{pmatrix} w_1 \\ \vdots \\ w_M \end{pmatrix}.
\]
The hypotheses show that $PE = I$, i.e., $EP = I$ and therefore $P$ gives the coefficients of the interpolation. \hfill \Box

Thus our aim is to construct a quadrature rule that preserves the orthogonality properties. We do so for each of the cases:

Proposition 8.10 (Circle). Let $\{t_j\}_{j=1}^{n}$ and $\{w_j\}_{j=1}^{n}$ be the $n$-point Gaussian quadrature nodes and weights with respect to $w^{-\frac{1}{2}}$ defined on $[-1, 1]$, as in Theorem 3.1.
Then the $2n$ polynomials $\{Y_{j,1}\}_{j=0}^{n-1}$, $\{Y_{j,2}\}_{j=1}^{n}$ are orthogonal with respect to the discrete inner product

$$
(f, g)_n := \sum_{j=1}^{n} w_j \left[ f(x_j, y_j)g(x_j, y_j) + f(x_j, -y_j)g(x_j, -y_j) \right],
$$

where $x_j = t_j$ and $y_j = y = \sqrt{1 - t_j^2}$.

**Proof.** For any $k$ and $\ell$, $Y_{k,1}$ and $Y_{\ell,2}$ are orthogonal with respect to the discrete inner product $\langle \cdot, \cdot \rangle_n$ by symmetry. For $k, \ell < n$, we have, due to the fact Gaussian quadrature is exact for all polynomials of degree $2n - 1$,

$$
\langle Y_{k,1}, Y_{\ell,1} \rangle = 2 \int_{-1}^{1} p_k(w_{-\frac{1}{2}}; x)p_\ell(w_{-\frac{1}{2}}; x) \frac{w(x)}{\sqrt{1 - x^2}} dx = 2 \sum_{j=1}^{n} w_j p_k(w_{-\frac{1}{2}}; t_j)p_\ell(w_{-\frac{1}{2}}; t_j) = \langle Y_{k,1}, Y_{\ell,1} \rangle_n.
$$

Similarly, for any $k, \ell \leq n - 1$, we have

$$
\langle Y_{k,2}, Y_{\ell,2} \rangle = \int_{-1}^{1} p_{k-1}(w_{\frac{1}{2}}; x)p_{\ell-1}(w_{\frac{1}{2}}; x)(1 - x^2) \frac{w(x)}{\sqrt{1 - x^2}} dx = \sum_{j=1}^{n} w_j (1 - t_j^2)p_{k-1}(w_{\frac{1}{2}}; t_j)p_{\ell-1}(w_{\frac{1}{2}}; t_j) = \langle Y_{k,2}, Y_{\ell,2} \rangle_n.
$$

as $p_{k-1}(w_{\frac{1}{2}}; x)p_{\ell-1}(w_{\frac{1}{2}}; x)(1 - x^2)$ is of degree $k + \ell \leq 2n - 2$.

This leaves only the case $k = \ell = n$. Since $x_j$ are precisely the roots of $p_n(w_{1/2})$, we actually have that $\langle Y_{n,1}, Y_{n,1} \rangle_n = 0$. On the other hand, $(1 - x^2)p_{n-1}(w_{1/2}; x)^2$ cannot vanish on $x_j$, as if it did $p_{n-1}(w_{1/2}; x)$ would also vanish at the $n$ points $x_j$ (as $x_j$ do not contain $\pm 1$), hence would be zero.

□

Before proceeding, we note that suitable Gauss–Lobatto points can be used to interpolate by the basis $\{Y_{j,1}\}_{j=0}^{n-1}$, $\{Y_{j,2}\}_{j=1}^{n-1}$ (if one endpoint is fixed) or $\{Y_{j,1}\}_{j=0}^{n}$, $\{Y_{j,2}\}_{j=1}^{n}$ (if two endpoints are fixed). Indeed, when $w(x) = 1$ these variants give different versions of the real-valued discrete Fourier transform.

A similar construction readily translates to each of the other cases. We omit the proofs as they are essentially the same as the circle case.

**Corollary 8.11** (Parabola). Let $\{t_j\}_{j=1}^{n}$ and $\{w_j\}_{j=1}^{n}$ be the $n$-point Gaussian quadrature nodes and weights with respect to $w_{-\frac{1}{2}}$ defined on $\mathbb{R}^+$, as in Theorem 4.1. Then the $2n$ polynomials $\{Y_{j,1}\}_{j=0}^{n-1}$, $\{Y_{j,2}\}_{j=1}^{n}$ are orthogonal with respect to the discrete inner product

$$
(f, g)_n := \sum_{j=1}^{n} w_j \left[ f(x_j, y_j)g(x_j, y_j) + f(-x_j, y_j)g(-x_j, y_j) \right],
$$

where $x_j = \sqrt{t_j}$ and $y_j = t_j$.

**Corollary 8.12** (Hyperbola, two branches). Let $\{t_j\}_{j=1}^{n}$ and $\{w_j\}_{j=1}^{n}$ be the $n$-point Gaussian quadrature nodes and weights with respect to $w_0$ defined on $\mathbb{R}^+$, as in Theorem 5.1. Then the $2n$ polynomials $\{Y_{j,1}\}_{j=0}^{n-1}$, $\{Y_{j,2}\}_{j=1}^{n}$ are orthogonal with respect to
the discrete inner product
\[ (f,g)_n := \sum_{j=1}^{n} w_j \left[ f(x_j, y_j)g(x_j, y_j) + f(-x_j, y_j)g(-x_j, y_j) \right], \]
where \( x_j = \sqrt{t_j^2 + 1} \) and \( y_j = t_j \).

**Corollary 8.13** (Hyperbola, one branch). Let \( \{t_j\}_{j=1}^{n} \) and \( \{w_j\}_{j=1}^{n} \) be the n-point Gaussian quadrature nodes and weights with respect to \( w \) defined on \( \mathbb{R}_+ \), as in Theorem 5.4. Then the 2n polynomials \( \{Y_{j,1}\}_{j=0}^{n-1}, \{Y_{j,2}\}_{j=1}^{n} \) are orthogonal with respect to the discrete inner product
\[ (f,g)_n := \sum_{j=1}^{n} w_j \left[ f(t_j, 0)g(t_j, 0) + f(0, t_j)g(0, t_j) \right]. \]

**Corollary 8.14** (Intersecting lines). Let \( \{t_j\}_{j=1}^{n} \) and \( \{w_j\}_{j=1}^{n} \) be the n-point Gaussian quadrature nodes and weights with respect to \( w \) defined on \( \mathbb{R} \), as in Theorem 6.1. Then the 2n polynomials \( \{Y_{j,1}\}_{j=0}^{n-1}, \{Y_{j,2}\}_{j=1}^{n} \) are orthogonal with respect to the discrete inner product
\[ (f,g)_n := \sum_{j=1}^{n} w_j \left[ f(t_j, 0)g(t_j, 0) + f(0, t_j)g(0, t_j) \right]. \]

**Corollary 8.15** (Parallel lines). Let \( \{t_j\}_{j=1}^{n} \) and \( \{w_j\}_{j=1}^{n} \) be the n-point Gaussian quadrature nodes and weights with respect to \( w \) defined on \( \mathbb{R} \), as in Theorem 7.1. Then the 2n polynomials \( \{Y_{j,1}\}_{j=0}^{n-1}, \{Y_{j,2}\}_{j=1}^{n} \) are orthogonal with respect to the discrete inner product
\[ (f,g)_n := \sum_{j=1}^{n} w_j \left[ f(t_j, -1)g(t_j, -1) + f(t_j, 1)g(t_j, 1) \right]. \]

9. Applications

We now discuss three applications of orthogonal polynomials on quadratic curves. The first section makes connections with known results for the Fourier extension problem. The second section shows that the approximation of univariate functions with certain singularities or near-singularities can be recast as interpolation of non-singular functions on quadratic curves, leading to robust and accurate approximation schemes. The last section applies this construction to solving differential equations with nearly singular variable coefficients, in particular, Schrödinger’s equation.

9.1. The Fourier extension problem. Our first example considers the Fourier extension problem, that is, approximating \( f(\theta) \) by a Fourier series
\[ f(\theta) \approx c_0 + \sum_{k=1}^{n} (c_k \cos k\theta + s_k \sin k\theta) \]
where we are only allowed to sample \( f \) in a sub-interval of \([\pi, \pi]\), without loss of generality, the interval \([-h, h]\). Usually, it is assumed that the samples of \( f \) are at evenly spaced points, but we consider a slightly more general problem where we are allowed to sample wherever we wish provided they are restricted to \([-h, h]\). Extensive
work on the Fourier extension problem exists including fast and robust algorithms, see the recent work of Mattheysen and Huybrechs \[7\] and references therein.

As noted by Huybrechs in \[6\], the Fourier extension problem is closely related to expansion in orthogonal polynomials on an arc if we let $x = \cos \theta$ and $y = \sin \theta$. In fact, Huybrechs constructed quadrature schemes for determining these coefficients numerically, which are very close to the proposed interpolation method above. Here we make the minor observation that via the construction in Proposition 8.10 we can guarantee this expansion interpolates. This presents an attractive scheme for automatic determination of minimal degree needed for approximation, at which point the methods proposed in \[7, 6\] can be used to re-expand in classical Fourier series.

9.2. Interpolation of functions with singularities. We now consider an application of orthogonal polynomials on hyperbolic curves: approximation of (nearly-)singular functions via interpolation. We consider the following three cases:

\[
\begin{align*}
  f(t) &= f(t, |t|), \\
  f(t) &= f(t, \sqrt{t^2 + \epsilon^2}), \\
  f(t) &= f(t, 1/t),
\end{align*}
\]

where $f(x, y)$ is a function smooth in $x$ and $y$, defined on the quadratic curves $y = x^2$, $y^2 = x^2 + \epsilon^2$ or $xy = 1$, respectively. Thus instead of attempting to approximate the (nearly-)singular function $f(x)$ on the real line, we will approximate the non-singular function $f(x, y)$ on the appropriate quadratic curve via interpolation by orthogonal polynomials in two variables, as in the preceding section. This leads to faster convergence than conventional polynomial interpolation.

9.2.1. Example 1: square-root singularity. Consider functions with singularities like $\sqrt{t^2 + \epsilon^2}$, for example

\[
f(t) = \sin(10t + 20\sqrt{t^2 + \epsilon^2})
\]

on the interval $-1 \leq t \leq 1$. We project $f(t)$ to the standard hyperbola using

\[
f(x, y) = f(\epsilon y) = \sin(10\epsilon y + 20\epsilon x)
\]

on the one-branch hyperbola $x^2 = y^2 + 1$, $x > 1$ and $y \in [-\epsilon^{-1}, \epsilon^{-1}]$ via the change of variables $t = y$ and $x = \sqrt{t^2 + \epsilon^2}$.

By Theorem 5.4, we can represent orthogonal polynomials in terms of univariate orthogonal polynomials. For concreteness, we choose: $w_0(t) = 1$ and hence $w_1(t) = t^2 - 1$, where $1 \leq t \leq L$ for $L = \sqrt{1 + 1/\epsilon^2}$. Here $w_0(t)$ is the Legendre weight, hence we have

\[
Y_{n,1}(x, y) = p_n(w_0; x) = P_n \left( \frac{2x - 1}{L - 1} - 1 \right)
\]

On the other hand, $w_1(t)$ is not a classical weight but we can construct its orthogonal polynomials numerically via the Stieltjes procedure [4, Section 2.2.3]; indeed, because the weight itself is polynomial, the procedure is exact provided a sufficient number of quadrature points are used to discretize the inner product. This step needs to be repeated for each $\epsilon$ as the interval length depends on $\epsilon$.

Following the previous section, we find the coefficients of the polynomial $f_n(x, y)$ that interpolates $f(x, y)$ at the $2n$ points $(x_j, \pm y_j)$, where $y_j = \sqrt{x_j^2 - 1}$ and $x_j$ are
In Figure 1, we plot the interpolant for 20 and 40 interpolation points, for $\epsilon = 0.01$. In Figure 2, we plot the pointwise error. We include the Chebyshev interpolant for comparison: the approximation built from orthogonal polynomials on the hyperbola converges rapidly, despite the almost-singularity inside the domain, whereas the Chebyshev interpolant requires significantly more points to achieve the same accuracy.

In Figure 3 we plot the coefficients of the interpolating polynomial for decreasing values of $\epsilon$. We include $\epsilon = 0$: this may appear to be a degenerate limit as $L \to \infty$, but under an affine change of variables we see that the weights tend to the intersecting lines case with $w(t) = 1$ for $0 \leq t \leq 1$ in a continuous fashion, hence we can employ the construction in Corollary 8.14. We observe super-exponential convergence for each

$$f_n(t) = f_n \left( \sqrt{1 + \frac{t^2}{\epsilon^2}} \cdot \frac{t}{\epsilon} \right)$$

interpolates $f(t)$ at the points $\pm \epsilon y_j$. 

the Gauss–Legendre points on the interval $[1, L]$. It follows that
Figure 2. The convergence of the interpolant of \( \sin(10t + 20\sqrt{t^2 + \epsilon^2}) \), for \( \epsilon = 0.01 \) for increasing number of interpolation points \( M \), comparing orthogonal polynomials on the hyperbola (left) to Chebyshev interpolation (right).

Figure 3. The calculated coefficients of the interpolating polynomial on the hyperbola for 100 interpolation points and \( \epsilon = 0.5, 0.05, 0.005, 0 \). The number of interpolation points is chosen sufficiently large that the interpolation coefficients approximate the true coefficients to roughly machine accuracy.
Figure 4. The condition number of the interpolation (Vandermonde) matrix associated to a naïve basis consisting of \( \{T_j(t)\}_{j=0}^{n-1} \) and \( \{\sqrt{t^2 + \epsilon^2}T_j(t)\}_{j=0}^{n-1} \) at 2n Chebyshev points (left, log-scale) compared to the interpolation (Vandermonde) matrix using OPs on the hyperbola at the associated 2n interpolation points (right, standar-scale) for \( \epsilon = 0.5, 0.05, 0.005, 0 \). The proposed scheme has only linear growth in condition number, compared to exponential growth for the naïve basis.

value of \( \epsilon \), with a rate uniformly bounded as \( \epsilon \to 0 \). This compares favourably with polynomial interpolation at Chebyshev points, which degenerates to slow algebraic convergence as \( \epsilon \to 0 \).

Note that there is an alternative approach of approximating the solution using standard bases, for example, we could naively write

\[
f(t) \approx \sum_{k=0}^{n-1} f_k T_k(t) + \sqrt{t^2 + \epsilon^2} \sum_{k=0}^{n-1} f_k^2 T_k(t).
\]
The benefit of the proposed construction in terms of orthogonal polynomials on the hyperbola is that the orthogonality ensures that the interpolation is well-conditioned, whereas the standard approach results in exponentially bad conditioning, see Figure 4. Recent advances in approximation with frames can overcome the issues with ill-conditioning for the approximation problem (see [7] and references), but at the expense of no longer interpolating the data. It remains open how to use these techniques for the solution of differential equations as in Example 3.

9.2.2. Example 2: essential singularity. We now consider a function that is smooth in $t$ and $1/t$, for example, 

$$f(t) = \sin(t + 2/t)$$

on the real line. We project $f$ to the two-branch hyperbola $x^2 = y^2 + 1$ by the change of variables $t = x - y$:

$$f(x, y) = f(x - y) = \sin((x - y + 2(x + y))$$

where we use the fact that if $t = x - y$ then $t^{-1} = x + y$ since $tt^{-1} = (x - y)(x + y) = x^2 - y^2 = 1$.

We repeat the procedure used in the previous example, this time with the Hermite weight:

1. Construct $Y_{n,1}(x, y)$ using Hermite polynomials, orthogonal with respect to $w(t) = e^{-t^2}$.
2. Construct $Y_{n,2}(x, y)$ using polynomials orthogonal with respect to $w(t) = (1 + t^2)e^{-t^2}$. This construction is performed numerically using the Stieltjes procedure, with Gauss–Hermite quadrature to discretize the inner product.
3. Calculate the coefficients of the interpolation polynomial $f_M(x, y)$, which equals $f(x, y)$ at the $M = 2\nu$ points $\{(\pm x_j, y_j)\}_{j=1}^\nu$, where $y_j$ are the $\nu$ Gauss–Hermite quadrature points and $x_j = \sqrt{y_j^2 + 1}$, via Corollary 8.12.
4. The function $f_M(t) = f(\frac{t + t^{-1}}{2}, \frac{t - t^{-1}}{2})$ interpolates $f(t)$ at the $M$ points $\{\pm x_j - y_j\}_{j=1}^\nu$.

In Figure 5 we plot the decay in the coefficients of the interpolating polynomial of $\sin(t + 2/t)$ calculated via the proposed quadrature rule, showing an exponential decay rate. We also plot the pointwise convergence of the interpolant, showing exponentially fast uniform convergence in compact sets bounded away from the singularity $t = 0$. Note the convergence is uniform everywhere (including at the singularity) in a weighted sense.

9.3. Solving differential equations with singular variable coefficients. As a final example, we consider the solution of Schrödinger’s equation with a nearly singular well:

$$-h^2u''(t) + V(t)u = \lambda u$$

where we take $h = 0.1$ and $V(t) = \sqrt{t^2 + \epsilon^2 + (t - 0.1)^2}$, and use Dirichlet conditions on the interval $-3 \leq t \leq 3$. As $\epsilon \to 0$ the potential becomes increasingly degenerate until it is non-differentiable and approaches $|t| + (t - 0.1)^2$. For large $\epsilon$ and $\epsilon = 0$ standard spectral method techniques are applicable using Chebyshev or piecewise Chebyshev approximations as implemented in Chebfun (via quantumstates command) [1] or ApproxFun.jl [8]. However, the computations quickly become infeasible as $\epsilon$ becomes
small but non-zero: for example, with $\epsilon = 0.1$ we require roughly 1000 coefficients (hence the solution of a $1000 \times 1000$ eigenvalue problem) to calculate the smallest eigenvalue, while with $\epsilon = 0.01$ we were unable to succeed even using 5000 coefficients.

As an alternative, we will use OPs on a hyperbola via the change of variables $t = y$ and $x = \sqrt{t^2 + \epsilon^2}$ so that the potential is well-resolved by our basis. We then discretise the differential equation using a collocation system using $2n - 2$ points as in the interpolation scheme above, where $2n$ is the total number of coefficients. For simplicity of implementation, the second derivatives of the basis are calculated using automatic-differentiation (via TaylorSeries.jl [2]), however, we could also achieve this analytically by differentiating the three-term recurrence: that is, if we have the recurrence coefficients of the univariate orthogonal polynomials we can differentiate...
the relationship

\[
(J - x) \begin{pmatrix} p_0(x) \\ p_1(x) \\ \vdots \end{pmatrix} = 0
\]

to find a recurrence relationship for the derivative,

\[
(J - x) \begin{pmatrix} p'_0(x) \\ p'_1(x) \\ \vdots \end{pmatrix} = \begin{pmatrix} p_0(x) \\ p_1(x) \\ \vdots \end{pmatrix},
\]

and thereby determine \(p'_n(x)\) by forward substitution. Finally, we impose Dirichlet conditions as two extra rows, leading to a generalised finite-dimensional eigenvalue problem. For \(\epsilon = 0.1\) we confirm the calculation matches that of a standard Chebyshev spectral method (to at least 10 digits).

In Figure 6 we plot the first 20 eigenstates with \(\epsilon = 0.01\). In Figure 7 we depict the calculated coefficients of the smallest energy eigenstate in OPs on the hyperbola. We can see that the first eigenstate continues to be resolved even for \(\epsilon = 0.001\), though there is some plateaux effect as \(\epsilon \to 0\). While the decay rate of the plateaux degenerates, the magnitude of the plateaux improves with smaller \(\epsilon\) hence we continue to achieve high accuracy computations.

10. Future work

We have explored orthogonal polynomials on quadratic curves, and shown for weights satisfying certain symmetry properties that they can be constructed explicitly using orthogonal polynomials in one variable. We have used these orthogonal polynomials as a basis to interpolate functions with singularities of the form \(|x|, \sqrt{x^2 + \epsilon^2}, \text{ and } 1/x,\)
FIGURE 7. The coefficients of the smallest energy eigenstate in OPs on the hyperbola for Schrödinger equation with nearly singular potential $V(t) = \sqrt{t^2 + \epsilon^2} + (t - 0.1)^2$ for $\epsilon = 0.1, 0.01, 0.001, 0.0001$, using a $400 \times 400$ collocation system.

where the coefficients of the interpolant are determined via quadrature rules. Exponential or super-exponential convergence was observed in each case. We showed that the construction is also applicable to solving differential equations with nearly singular variable coefficients.

Further applications of this work are to function approximation, quadrature rules, and solving differential equations involving other quadratic singularities, for example, functions that are smooth in $x$ and $\sqrt{x}$ on $[0, 1]$. Such functions arise naturally in numerical methods for half-order Riemann–Liouville and Caputo fractional differential equations [5]. Orthogonal polynomials on a half-parabola—that is $y^2 = x$, $0 < x < 1$—would form a natural and convenient basis for approximating such functions. However, we are left with the task of constructing orthogonal polynomials for a weight that does not satisfy the requisite symmetry properties that allowed for reduction to univariate orthogonal polynomials.

Orthogonal polynomials on quadratic curves are also of use in partial differential equations on exotic geometries, for example, they have been recently used by Snowball and the first author for solving partial differential equations on disk slices and trapeziums [12]. Finally, we mention that the results can be extended to higher dimensions, in particular to quadratic surfaces of revolution [10]. It is also likely possible to reduce orthogonal polynomials on higher dimensional geometries satisfying suitable symmetry relationships to one-dimensional orthogonal polynomials, as is the case for multivariate orthogonal polynomials with weights that are invariant under symmetry reductions [3].

A natural question that arises is the structure of orthogonal polynomials on general (higher than quadratic) algebraic curves and surfaces. A closely related question is the structure of orthogonal polynomials inside algebraic curves and surfaces. It is unlikely that we will be able to reduce orthogonal polynomials on general algebraic geometries
to one variable orthogonal polynomials, so other techniques will be necessary. Understanding this structure could lead to further applications in function approximation and numerical methods for partial differential equations, as well as theoretical results.
