ABOUT COVER

Miguel A De Gregorio, BM BCh, MD, PhD, Chief Doctor, Professor, Research Scientist, Department of Radiology, Medicine Faculty, University of Zaragoza, Zaragoza 50009, Spain. mgregori@unizar.es

AIMS AND SCOPE

The primary aim of World Journal of Radiology (WJR, World J Radiol) is to provide scholars and readers from various fields of radiology with a platform to publish high-quality basic and clinical research articles and communicate their research findings online.

WJR mainly publishes articles reporting research results and findings obtained in the field of radiology and covering a wide range of topics including state of the art information on cardiopulmonary imaging, gastrointestinal imaging, genitourinary imaging, musculoskeletal imaging, neuroradiology/head and neck imaging, nuclear medicine and molecular imaging, pediatric imaging, vascular and interventional radiology, and women's imaging.

INDEXING/ABSTRACTING

The WJR is now abstracted and indexed in Emerging Sources Citation Index (Web of Science), PubMed, PubMed Central, China National Knowledge Infrastructure (CNKI), China Science and Technology Journal Database (CSTJ), and Superstar Journals Database.

RESPONSIBLE EDITORS FOR THIS ISSUE

Production Editor: Yan-Xiaojian Wu; Production Department Director: Yan-Xiaojian Wu; Editorial Office Director: Jia-Ping Yan.

Observational Study

Cone beam computed tomographic evaluation of pharyngeal airway in North Indian children with different skeletal patterns

Anuraj Singh Kochhar, Maninder Singh Sidhu, Ritasha Bhasin, Gulsheen Kaur Kochhar, Himanshu Dadlani, Jagpreet Sandhu, Bobby Virk

Abstract

BACKGROUND
In growing patients with skeletal discrepancies, early assessment of functional factors can be vital for the restoration of normal craniofacial growth.

AIM
To compare airway volumes in patients with mandibular retrognathism with the normal anteroposterior skeletal relationship, thereby assessing the association between cephalometric variables and airway morphology.

METHODS
Cone-beam computed tomography volume scans, and lateral cephalograms, 3-dimensional airway volume and cross-sectional areas of 120 healthy children (54 boys and 66 girls mean age 15.19 ± 1.28) which were done for orthodontic
study participants, or their legal guardian, provided informed written consent prior to study enrollment.

Conflict-of-interest statement: All the authors have no conflict of interest related to the manuscript.

Data sharing statement: No additional data are available. The original anonymous dataset is available on request from the corresponding author.

STROBE statement: The authors have read the STROBE Statement-checklist of items, and the manuscript was prepared and revised according to the STROBE Statement-checklist of items.

Open-Access: This article is an open-access article that was selected by an in-house editor and fully peer-reviewed by external reviewers. assessment were evaluated. The subjects were divided into 2 groups based on the angle formed between point A, Nasion and point B (ANB) values and cephalometric variables (such as anterior and posterior facial height, gonial angle etc.) airway volumes, and cross-sectional measurements were compared using independent t tests. Pearson’s correlation coefficient test was used to detect any relationship of different parts of the airway and between airway volume and 2-dimensional cephalometric variables.

RESULTS
Means and standard deviations for cephalometric, cross-sectional, and volumetric variables were compared. ANB, mandibular body length and facial convexity were statistically highly significant (P < 0.01) whereas condyion to point A, nasal airway and total airway volume (P < 0.05) were statistically significant. The nasal airway volume and the superior pharyngeal airway volume had a positive correlation (P < 0.01), nasal airway was correlated to middle (P < 0.05) and total airway superior had a relation with middle (P < 0.05), inferior and total airway (P < 0.05), middle was related to all other airways; inferior was also related to all the airways except nasal. Lateral cephalometric values were positively correlated with the airway volume with Frankfurt Mandibular Plane Angle and facial convexity showed significant correlations with total airway volume (P < 0.05). Additionally, ANB angle was significantly correlated with total airway volume and superior airway (P < 0.05).

CONCLUSION
The mean total airway volume in patients with retrognathic mandible was significantly smaller than that of patients with a normal mandible.

Core Tip: With the advent of cone beam computed tomography, analysis of airway has become possible. Patients who present with retrognathic jaw or anterior-posterior skeletal discrepancy have been contemplated to have reduced pharyngeal airway. When comparing the airway volumes of 120 healthy individuals with mandibular retrognathism and normal anteroposterior skeletal relationship, the mean total airway volume of patients with the angle formed between point A, Nasion and point B (ANB) more than 4 was significantly smaller than that of patients with ANB less than 4. The sub-volumes in the pharyngeal airway showed a positive correlation with each other. Frankfurt Mandibular Plane Angle and facial convexity and mandibular body length also had a significant interrelationship with total volume of airway.

INTRODUCTION
Respiratory function plays a substantial role in orthodontic diagnosis and treatment planning. An association between the respiratory mode and facial morphology has been observed in various studies utilizing cephalograms. Furthermore, a link between Class II Division 1 malocclusion and upper pharyngeal airway obstruction as well as mouth breathing, was demonstrated by Angle in 1907. Various authors have presented characteristics related to obstructed breathing. Primary clinical features of respiratory obstruction syndrome have been identified by Ricketts as tonsil and adenoid enlargement, narrow nostrils, open bite, cross bite, and tongue thrusting.
The role of the upper anatomy in the craniofacial complex development is usually considered substantial. Impaired breathing can be a result of narrow pharyngeal airway, which can further lead to diminished levels of growth hormone in growing children or obstructive sleep apnea in mature individuals. Diminished airway associated with obstructive sleep apnea tends to be typical in patients with Angle class II malocclusion, displaying retrognathic mandible and sagittal discrepancy.

Early diagnosis and evaluation of the functional factors in growing children with skeletal discrepancy and features of adenoid hypertrophy (adenoid faces) might be pivotal to restore proper craniofacial growth and treatment outcome stability. Pharyngeal airway measurements have usually been conducted by landmark identification followed by measurements of different lengths and areas in the pharyngeal region.

Although there is an avalanche of studies regarding airway morphology and its effects on craniofacial growth, most studies have used 2-dimensional (2D) techniques, frontal or lateral cephalograms, with inadequate assessment of length and areas. A technique for 3-dimensional (3D) visualization, utilized frequently is computed tomography. However, a huge impediment to its use is the large radiation dose. The radiation dose can be minimized to one-fifth, while not compromising on quality, with modern cone beam computed tomography (CBCT), due to which it is becoming increasingly popular.

Volumetric measurements of the pharyngeal airway space (PAS) and, narrowing or obstruction can be localized utilizing CBCT. As narrowing or obstruction of the pharyngeal airway can be present in patients with altered maxillo-mandibular relationship and can be associated with sleep, as well as Obstructive Sleep Apnoea Syndrome, this analysis can be beneficial in the orthodontic diagnosis and planning orthognathic surgery. Therefore, the aim of the present study was to compare the pharyngeal airway volumes in children with varying anteroposterior maxillo-mandibular relationships (ANB angles that is the angle formed between point A, Nasion and Point B) and study the possible correlations between different cephalometric variables and the airway morphology in these children.

MATERIALS AND METHODS

Following the ethical clearance from the institutional review board, records of 150 children who visited the outpatient Department of Orthodontics were examined. Of this, CBCT scans of 120 healthy North Indian children (54 boys and 66 girls mean age 15.19 ± 1.28) were selected, after the following exclusion criteria was applied: History of any upper respiratory infection, pharyngeal pathology (like adenoid hypertrophy and tonsillitis) or a history of adenoid or tonsil removal (Table 1).

CBCT volume scans of all subjects were obtained by using the I-Cat CBCT unit (Imaging Sciences Hatfield, PA, United States), and the imaging protocol used a 17 cm × 21 cm field of view to include the entire craniofacial anatomy. The images were standardized with the subject seated in a chair, machine settings of 120 kV-5 mA-0.25 mm voxel, and scan time of 20 s. Patients, following the standard protocol of acquiring the scans in a natural head position, and their jaws in maximum intercuspation with the lips and tongue in resting position were used. For volume evaluation/measurement and cephalometric analysis, the axial images were transferred to InVivo Dental software (Anatomage, San Jose, CA, United States) The 3D images were reoriented using the Frankfort horizontal (FH) plane as the reference plane for uniformity and to reduce errors. A line joining the right and left portions, located in the most latero-superior point of the external auditory meatus, to the right orbitale was constructed as the FH plane (Figure 1).

2D cephalometric images were derived from the CBCT scans by using SUPER CEPH feature of the software In Vivo Dental, and the images were imported into Nemoceph® (Dental Studio NX 2006 version 6.0) (Figure 2). Landmark identifications and physical measurements were performed by the same investigator. Using the software Downs, Steiner, Jarabak, Mc Namara and Tweed Merrifield analysis were done in order to classify patients (Tables 1 and 2).

Cross-sectional views of the pharyngeal airway in the 5 planes: a, represents the length (axial slice) or height (frontal slice) of the airway defined by the greatest distance in the anteroposterior or vertical direction of the airway cross-section; b is the width of the airway defined by the greatest distance in the right and left directions of the airway cross-section and 5 volumes A, right lateral view and B, frontal view of volume rendered images. a, Anterior nasal plane; b, posterior nasal plane; c, upper

FH: Frankfurt horizontal; 3D: Three-dimensional.

pharyngeal plane; d, middle pharyngeal plane; and e, lower pharyngeal plane (Table 3 and Figures 3 and 4). Cross-sectional planes of the nasal cavity were perpendicular to the FH plane, whereas the pharyngeal cross-sections are parallel to the FH plane. Although these cross-sections are not directly perpendicular to the long axis of the airway, the FH plane was used as a reference plane to standardize the plane orientation and minimize error in identifying the studied cross-sectional planes. Cross-sectional measurements, that is width and length, were computed in frontal and axial views to provide linear accuracy.

Volumetric renderings of the subjects' CBCT scans were acquired with the In Vivo Dental software, and we proceeded with volumetric analysis of the defined airways. 3D image inversion to convert negative image to a positive value was done, which is required as the airway is a void space. This process removes the hard and soft tissues of the image around the airway and embodies the airway spaces of the craniofacial region including the paranasal sinuses and other empty spaces. Furthermore, to isolate the required airway section and remove structures that were not necessary, sculpting was performed which was an inherent feature of the software. Threshold values were thereafter altered to remove the artifacts and enhance the selected region of airway. Lastly, designated airway volume was computed in cubic millimeters.

Statistical analysis

Descriptive statistics including the mean and standard deviation for each group were calculated by using SPSS for Windows software (version 20). Differences between

<sup>a</sup>Correlation is significant at 0.05 level.
<sup>b</sup>Correlation is significant at 0.01 level.

Groups were tested by using independent t tests. Pearson’s correlation coefficient test was used to detect any relationship of different parts of the airway and between airway volume and 2D cephalometric variables.

RESULTS

Means and standard deviations for cephalometric, cross-sectional, and volumetric variables were compared. Table 4 gives the comparison results of groups I and II. ANB, mandibular body length, facial convexity were statistically highly significant (P < 0.01) whereas condylion to point A, nasal airway and total airway volume (P < 0.05) were statistically significant. Cross-sectional and volumetric measurements at different levels when compared were statistically insignificant. However, total airway volume was significantly greater in group I (P < 0.05).

Table 3 show the correlations among the studied variables. The nasal airway volume and the superior pharyngeal airway volume had a positive correlation (P < 0.01), nasal airway was correlated to middle (P < 0.05) and total airway superior had a relation with middle (P < 0.05), inferior and total airway (P < 0.05), middle was related to all other airways, inferior was also related to all the airways except nasal (Table 5). Lateral cephalometric values were positively correlated with the airway volume with Frankfurt Mandibular Plane Angle (FMA) and facial convexity showed significant correlations with total airway volume (P < 0.05). Additionally, ANB angle was significantly correlated with total airway volume and superior airway (P < 0.05).

### DISCUSSION

In the last few decades’ airway assessment has been done using nasal resistance and airflow tests, nasoendoscopy and lateral cephalograms<sup>15</sup>. In the current study, CBCT produced anatomically precise images, sans magnification or distortion were reconstructed 3 dimensionally to completely understand the pharyngeal airway anatomy of growing children in all dimensions (sagittal, transverse and frontal)<sup>11,14</sup>. Generally, a requisite for 3D imaging such as conventional CT or magnetic resonance...

Figure 1 Standardisation of the images.

Figure 2 Cone beam computed tomography derived cephalogram and analysis.

imaging is for the patients to be supine. However, due to the effect of gravity on the soft tissues enveloping the oropharyngeal cavity, there are substantial anatomical changes in the airway[16].

Hsu et al[17] further found that the minimum of PAS and linear distance along perpendicular changes from the most upper anterior point of the hyoid bone to mandibular plane, as the position of body is changed from upright to supine[17]. Nevertheless, in recent times, advancements in CBCT have permitted axial CT images to be acquired in upright sitting posture, which is more valid for our study.

Owing to this study’s retrospective design, direct examination of the nasopharyngeal functions of the patients was not possible and previous clinical charts and diagnoses for orthodontic treatment were used to select subjects. Nonetheless, a study by Laine-Alava et al[18] stated that there is no effect of a history or symptoms of upper respiratory disease on variables related to naso-respiratory function when the
measurements are made during an asymptomatic period, which justifies the retrospective format of our study[18].

2D lateral cephalometric images were created from the CBCT scans to allocate the subjects to the 2 groups, and to assess correlations among the cephalometric parameters and the pharyngeal airway volumes. Linear accuracy of the CBCT-derived lateral cephalometric images has been studied in the past[19,20]. The classification of the subjects based on their anteroposterior skeletal relationships, was done utilizing north Indian standards for the ANB angle[21]. Additionally, previously it has been demonstrated that the prepubertal ANB angle and the angle of convexity measured have high prediction accuracy for postpubertal anteroposterior jaw relationships[19,22]. In the current study, the anteroposterior analyses displayed statistically significant differences further confirming that the ANB angle, which was used to classify our subjects, was a reliable parameter[22].

Previous studies have presented excellent intra-rater reliability values of InVivo 5 software, hence in the present study the InVivo 5 software was used to analyse the pharyngeal volume[14,23]. In the current study, no sexual dimorphism in any cross-sectional and volumetric measurements was observed between the two sexes. These findings were in agreement with the study by Ceylan et al[24] and de Freitas et al[25]. Similarly, in a study by Xu et al[26] in 2019, no significant difference was observed in patient sex as well as age.

In groups I and II ANB, mandibular body length and facial convexity were statistically highly significant (P < 0.01) whereas condylion to point A, nasal airway and total airway volume (P < 0.05) were statistically significant. Although group I demonstrated greater cross-sectional areas and volumetric measurements of the sub-regions of the pharyngeal airway, this was statistically insignificant signifying lack of correlation between segmental airway capacities and mandibular deficiencies. This was in accordance with Di Carlo et al[27] who did not find a direct correlation between individual skeletal patterns, and overall upper airway anatomy. Moreover, former 2D studies also asserted a lack of relationship between airway dimensions and malocclusion class[12,21]. Ceylan et al[24] stated that despite skeletal anteroposterior relationship changes, the airway dimensions remain constant, owing to postural changes in the pharyngeal structures. However, certain authors emphasized that upper airway dimensions vary according to different skeletal classes, developmental ages, and gender[1].

Nasal airway was positively correlated with middle and total airways. This may be justified by the location of the 2 sections, that are just superior to hard palate and not anatomically adjacent, yet there is direct correlation of their volumetric dimensions. The sections superior airway with middle, inferior and total airway with superior, middle and total airway display significant correlations. According to Ricketts[11] and Dunn et al[28], a restricted nasopharyngeal airway width is associated with mouth breathing, because it is readily obstructed by adenoid enlargement. Total airway was positively correlated with all superior, middle and inferior airways in our study.

The negative correlation of the ANB angle and the total airway can be explained by...
group I (ANB less than 4) having significantly greater airway volume than group II (ANB more than 4). Mandibular body length and total airway volume were both significantly greater in group I, demonstrating a positive correlation. Total airway volume had significant association with ANB angle and mandibular body length (anterior-posterior discriminants) supporting the intergroup comparison of different anterior-posterior skeletal patterns in the study. Similar results were observed by Lopatienė et al\textsuperscript{29}, where statistically significantly narrower airways were found in patients with ANB more than 4.

Alhammadi et al\textsuperscript{30} and Xu et al\textsuperscript{26} also concluded that patients with skeletal Class II presented with reduced glossoharyngeal airway volume, larger total minimum constricted area in average faces and more nasal minimum constricted area in long faces. Hwang et al\textsuperscript{31} reported that a constricted nasopharyngeal airway is associated with retruded mandible and maxilla.

A significant correlation exists between the skeletal facial pattern and upper airway dimensions according to a study done by Shokri et al\textsuperscript{32}, who concluded that the total
Airway volume and the mean airway area of class III patients were larger than those in class II patients.

**Limitation**

In the present study we did not evaluate class III malocclusion patients, also all the patients were scanned in a sitting upright position so conclusion about obstructive sleep apnea cannot be derived. But there is strong evidence from the large sample size that mandible backward position is correlated with reduced airway.

**CONCLUSION**

The mean total airway volume of patients with ANB more than 4 was significantly smaller than that of patients with ANB less than 4. The sub volumes in the pharyngeal airway showed a positive correlation with each other. FMA and facial convexity and mandibular body length also had a significant interrelationship with total volume of airway.

**ARTICLE HIGHLIGHTS**

**Research background**

Diminished airway associated with obstructive sleep apnea tends to be typical in patients with Angle class II malocclusion, displaying retrognathic mandible and sagittal discrepancy. Early diagnosis and evaluation of the functional factors in growing children with skeletal discrepancy and features of adenoid hypertrophy (adenoid faces) might be pivotal to restore proper craniofacial growth and treatment outcome stability.

**Research motivation**

A lot of data has been published related to the identification of airway in the general population, even comparing different cone beam computed tomography machines for the same. However, there is a paucity of data on tomographic evaluation of airways in different skeletal patterns, which is often challenging due to their morphology and plays a vital role in their treatment planning.

**Research objectives**

Comparing the airway volumes in patients with mandibular retrognathism and those with the normal anteroposterior skeletal relationship.

**Research methods**

Cone-beam computed tomography volume scans, and lateral cephalograms, 3-dimensional airway volume and cross-sectional areas of 120 healthy children which were done for orthodontic assessment was evaluated. The subjects were divided into 2 groups based on the angle formed between point A, Nasion and Point B (ANB) values and cephalometric variables (such as anterior and posterior facial height, gonial angle etc.) airway volumes, and cross-sectional measurements were compared using independent t tests. Pearson’s correlation coefficient test was used to detect any relationship of different parts of the airway and between airway volume and 2-dimensional cephalometric variables.

**Research results**

Means and standard deviations for cephalometric, cross-sectional, and volumetric variables were compared. ANB, mandibular body length, facial convexity was statistically highly significant whereas condylion to point A, nasal airway and total airway volume were statistically significant. The nasal airway volume and the superior pharyngeal airway volume had a positive correlation, nasal airway was correlated to middle and total airway superior had a relation with middle, inferior and total airway, middle was related to all other airways, inferior was also related to all the airways except nasal. Lateral cephalometric values were positively correlated with the airway volume with Frankfurt Mandibular Plane Angle and facial convexity showed significant correlations with total airway volume. Additionally, ANB angle was significantly correlated with total airway volume and superior airway.
Research conclusions
Position of the mandible has positive correlation with the airway volume. Retrognathic mandible showed decreased overall airway in patients. Facial convexity and length of the mandible also influence the airway.

Research perspectives
The current study gives direction for future research on a larger cohort related to mandibular position and airway, linking the two for timely maxillo-facial orthopedic treatment interventions.
