Combining phosphonic acid-functionalized anchoring ligands with asymmetric ancillary ligands in bis(diimine)copper(I) dyes for dye-sensitized solar cells

Annika Büttner, Sven Y. Brauchli, Raphael Vogt, Edwin C. Constable and Catherine E. Housecroft

A ‘surfaces-as-ligands’ strategy is used to assemble heteroleptic copper(I) dyes \([\text{Cu}(\text{L}_{\text{anchor}})(\text{L}_{\text{ancillary}})]^+\) on FTO/TiO\(_2\) electrodes for dye-sensitized solar cells (DSCs). The anchoring domain, \(\text{L}_{\text{anchor}}\), is either (6,6‘-diphenyl-2,2‘-bipyridine)-4,4‘-diyl bis(4,1-phenylene)bis(phosphonic acid) (1) or ((6,6‘-dimethyl-2,2‘-bipyridine)-4,4‘-diyl bis(4,1-phenylene)bis(phosphonic acid)) (2). Asymmetric ancillary ligands with a 2,2‘-bipyridine metal-binding domain are used to counter the sterically-demanding 6,6‘-diphenyl-substitution pattern in anchor 1: \(\text{L}_{\text{ancillary}} = 6\text{-methyl}-4\text{-phenyl}-2,2‘\text{-bipyridine (3)}, 6\text{-methyl}-4\text{-}(4\text{-bromophenyl})-2,2‘\text{-bipyridine (4)}, 6\text{-methyl}-4\text{-}(4\text{-methoxyphenyl})-2,2‘\text{-bipyridine (5)}\) or 6-methyl-4-(3,4,5-trimethoxyphenyl)-2,2‘-bipyridine (6). Solid-state absorption spectra of adsorbed \([\text{Cu}(1)(\text{L}_{\text{ancillary}})]^+\) and \([\text{Cu}(2)(\text{L}_{\text{ancillary}})]^+\), and external quantum efficiency (EQE) spectra of DSCs containing these dyes confirm that incorporation of 6,6‘-diphenyl-substituted 1 leads to a broadened spectral response at lower energies compared to dyes with anchor 2; dye-loading is higher for \([\text{Cu}(2)(\text{L}_{\text{ancillary}})]^+\) than for \([\text{Cu}(1)(\text{L}_{\text{ancillary}})]^+\), and EQE\(_{\text{max}}\) is \(>41\%\) for \([\text{Cu}(2)(\text{L}_{\text{ancillary}})]^+\) compared to \(<12\%\) for \([\text{Cu}(1)(\text{L}_{\text{ancillary}})]^+\). Enhanced values of the short-circuit current density \(J_{\text{sc}}\) are observed on going from anchor 1 to 2, independent of \(\text{L}_{\text{ancillary}}\). For the series of \([\text{Cu}(2)(\text{L}_{\text{ancillary}})]^+\) dyes, photoconversion efficiencies (confirmed using four DSCs per dye) vary with \(\text{L}_{\text{ancillary}}\) in the order 3 \(>\) 5 \(>\) 6 \(>\) 4 on the day of DSC assembly, and 5 \(>\) 3 \(>\) 6 \(>\) 4 after a week. The best performing DSCs achieve efficiencies of \(\sim 37\%\) relative to N719 set at 100%.

Introduction

Since the discovery by Sauvage and coworkers\(^\dagger\) that copper(I) sensitizers combined with wide band-gap semiconducting metal oxides such as TiO\(_2\) or ZnO could be used for photoconversion, significant progress has been made in the development of homoleptic \([\text{Cu}(\text{N–N})_2]^+\) and heteroleptic \([\text{Cu}(\text{N–N})(\text{N–N})']^+\) sensitizers (N–N = diimine ligand) in dye-sensitized solar cells (DSCs).\(^\dagger\)–\(^\ddagger\) The advantages of copper dyes over conventional ruthenium dyes lie in the Earth abundance and lower cost of copper over ruthenium. However, while photon-to-electrical current conversion efficiencies (\(\eta\)) for ruthenium dyes reach \(\approx 12\%\),\(^\dagger\)–\(^\ddagger\) the efficiencies of DSCs containing copper(I) dyes have only recently surpassed 3% (relative to \(\approx 7.5\%\) for the dye N719 used as a reference).\(^\ddagger\)–\(^\ddagger\) In an n-type DSC, heteroleptic \([\text{Cu}(\text{N–N})(\text{N–N})']^+\) dyes anchored to TiO\(_2\) are preferred to homoleptic dyes because their electronic properties are readily tuned to a ‘push–pull’ design to encourage electron transfer from electrolyte, through the dye to the semiconductor. One ligand \((\text{L}_{\text{anchor}})\) in the heteroleptic dye is designed to anchor the dye to the TiO\(_2\) surface, and the second \((\text{L}_{\text{ancillary}})\) can be variously functionalized. The exceptional global efficiencies of 4.42% and 4.66% reported by Odobel and coworkers\(^\ddagger\) were achieved using the heteroleptic \([\text{Cu}(\text{L}_{\text{anchor}})(\text{L}_{\text{ancillary}})]^+\) dyes shown in Scheme 1 in which both anchoring and ancillary ligands are designed to encourage electron transfer from electrolyte, through the dye to the semiconductor.
ligands contain 6,6′-substituted 2,2′-bipyridine (bpy) metal-binding domains. The use of bulky mesityl groups in one ligand stabilizes the copper(I) complex with respect to ligand dissociation, permitting isolation of the dye before TiO₂ surface functionalization. In contrast, we have applied the lability of bis(diimine) copper(I) complexes to assemble sensitizers on TiO₂ in our ‘surfaces-as-ligands’ approach.¹¹

As part of our continued efforts to enhance the performance of copper(I) sensitizers, we recently described the use of the phosphonic acid anchor 1 (Scheme 2) which contains phenyl substituents in the 6,6′-positions of the bpy unit. We have previously shown that phosphonic acid anchoring groups are preferred over carboxylic acids in copper(I) dyes, and the 6,6′-diphenyl substituents in 1 not only help to shield the copper(I) centre but also improve light absorption towards the red-end of the visible spectrum.¹² One of the major hurdles to overcome with copper(I) dyes is broadening their spectral responses. Comparisons of DSC performances of dyes with anchor 1 or 2 (the 6,6′-dimethyl analogue of 1, Scheme 2) and common ancillary ligands which contained 6,6′-bipyridine (bpy) metal-disubstituted bpy units.

Experimental

General

¹H and ¹³C NMR spectra were recorded on a Bruker Avance III-500 or 400 MHz NMR spectrometer; chemical shifts were referenced to residual solvent peaks with respect to δ(TMS) = 0 ppm. Solution and solid state absorption spectra were recorded using a Cary 5000 spectrophotometer. Electrospray ionization (ESI) mass spectra were recorded on a Bruker Daltonics Inc. microflex instrument.

Compounds 3a, 6a and 1-(2-oxopropyl)pyridinium chloride, have previously been reported, and [Cu(NCMe)₄][PF₆] was prepared as described in the literature. The dye N719 was purchased from Solaronix. The syntheses of compounds 1, 3–6 are reported in the ESI.†

[Cu(3)]²[PF₆]

Compound 3 (0.500 g, 2.03 mmol) and [Cu(NCMe)₄][PF₆] (0.378 g, 1.02 mmol) were dissolved in MeCN (25 mL) and stirred overnight (≈ 15 h) at room temperature. The solution was concentrated under vacuum and Et₂O (25 mL) was added. As no precipitate formed, the solution was filtered solvent removed from the filtrate under vacuum. [Cu(3)][PF₆] was isolated as a dark red-orange solid (1.19 g, 1.70 mmol, 83.7%). ¹H NMR (500 MHz, CD₂Cl₂) δ/ppm 8.55 (dd, J = 5.0, 1.6 Hz, 2H, H⁶), 8.45 (d, J = 8.1 Hz, 2H, H⁵), 8.38 (d, J = 1.8 Hz, 2H, H⁸), 8.13 (td, J = 7.6, 1.6 Hz, 2H, H⁴), 7.84 (m, 4H, CH₂), 7.71 (d, J = 1.9 Hz, 2H, H⁷), 7.59 (m, 8H, H⁵–⁶), 2.37 (s, 6H, HMe). ¹³C NMR (126 MHz, CD₂Cl₂) δ/ppm 158.2 (CB₆), 153.0 (CA₂/B₂), 152.4 (CA₂/B₂), 152.4 (CA₂/B₂), 151.1 (CA₂), 149.2 (CA₂), 138.6 (CA₂), 137.6 (CA₂), 130.5 (CA₂), 129.9 (CA₂), 127.7 (CA₂), 126.8 (CA₂), 124.3 (CB₂), 122.6 (CA₂), 117.7 (CA₂), 25.7 (CA₂). ESI-MS m/z 555.2 [M – PF₆]⁺ (calc. 555.2), UV-VIS (see text). Found C 58.39, H 4.37, N 8.35; C₃₄H₂₈CuF₆N₄P requires C 58.24, H 4.03, N 7.99%.

[Cu(4)]²[PF₆]

The method was as for [Cu(3)][PF₆] but starting with ligand 4 (0.350 g, 1.08 mmol) and [Cu(NCMe)₄][PF₆] (0.201 g, 0.540 mmol). [Cu(4)][PF₆] was isolated as a dark red-orange solid (0.835 g, 0.972 mmol, 90.0%). ¹H NMR (500 MHz, CD₂Cl₂) δ/ppm 8.54 (d, J = 4.6 Hz, 2H, H⁶), 8.46 (d, J = 8.1 Hz, 2H, H⁵), 8.35 (s, 2H, H⁸), 8.14 (t, J = 7.3 Hz, 2H, H⁷), 7.71 (m, 8H, H⁵–⁶), 7.67 (s, 2H, H⁸), 7.59 (m, 2H, H⁵), 2.35 (s, 6H, HMe). ¹³C NMR (126 MHz, CD₂Cl₂) δ/ppm 158.2 (CB₆), 153.0 (CA₂), 152.4 (CA₂), 152.4 (CA₂), 151.1 (CA₂), 149.3 (CA₂), 138.8 (CA₂), 137.6 (CA₂), 130.5 (CA₂), 129.9 (CA₂), 127.7 (CA₂), 126.8 (CA₂), 124.3 (CB₂), 122.6 (CA₂), 117.7 (CA₂), 25.7 (CA₂). ESI-MS m/z 713.0 [M – PF₆]⁺ (calc. 713.0). UV-VIS (see text). Found C 47.59, H 3.37, N 6.78; C₃₄H₃₆BrCuF₄N₄P requires C 47.54, H 4.03, N 6.52%.
[Cu(5)]PF₆

The method was as for [Cu(3)]PF₆ but starting with 5 (0.500 g, 1.81 mmol) and [Cu(NCMe)]PF₆ (0.337 g, 0.905 mmol). [Cu(5)]PF₆ was isolated as a dark red-orange solid (1.16 g, 1.52 mmol, 84.2%). ¹H NMR (500 MHz, CD₂Cl₂) δ/ppm 8.53 (d, J = 4.9 Hz, 2H, H⁵⁶), 8.44 (d, J = 8.1 Hz, 2H, H⁵⁸), 8.34 (s, 2H, H⁶¹), 8.12 (m, 2H, H⁴⁵), 7.80 (d, J = 8.4, 4H, H⁴⁴), 7.66 (s, 2H, H⁵⁵), 7.57 (m, 2H, H⁴⁶), 7.11 (d, J = 8.4 Hz, 4H, H⁴⁴), 3.90 (s, 6H, HMe), 2.33 (s, 6H, HMe). ¹³C NMR (126 MHz, CD₂Cl₂) δ/ppm 161.9 (C⁴), 158.0 (C⁶), 153.2 (C²), 152.3 (C⁸), 150.5 (C⁶), 149.2 (C⁶), 138.5 (C⁴), 129.6 (C⁵), 129.0 (C⁷), 126.7 (C⁸), 123.6 (C⁶), 122.5 (C⁷), 117.0 (C⁵), 115.4 (C⁷), 56.1 (COMe), 25.8 (CMe). ESI-MS m/z 615.2 [M – PF₆]⁺ (calc. 615.2). UV-VIS (see text). Found C 55.43, H 4.37, N 7.60; C₃₆H₃₂CuF₆N₄O₂P requires C 55.37, H 4.38, N 7.62.

[Cu(6)]PF₆

A solution of [Cu(NCMe)]PF₆ (0.716 g, 1.92 mmol) in CH₂Cl₂ (5–10 mL) was added dropwise to a solution of 6 (1.29 g, 3.84 mmol) in CH₂Cl₂ (20 mL). The reaction mixture was stirred overnight (15 h) at room temperature. The solution was concentrated under vacuum and Et₂O (25 mL) was added; the product did not precipitate, and therefore all the solvent was removed under vacuum and the residue redissolved in MeCN (≈ 25 mL). Et₂O (20 mL) was added, the mixture was filtered and the solvent was removed from the filtrate to yield [Cu(6)]PF₆ as a dark red-orange solid (2.41 g, 2.73 mmol, 71.2%). ¹H NMR (500 MHz, CD₂Cl₂) δ/ppm 8.54 (d, J = 4.4 Hz, 2H, H⁶⁶), 8.47 (d, J = 8.0 Hz, 2H, H⁶⁸), 8.32 (s, 2H, H⁶¹), 8.14 (m, 2H, H⁶⁸), 7.66 (s, HMe), 7.58 (m, 2H, H⁴⁴), 6.98 (s, 4H, H⁴⁴), 3.98 (s, 12H, HMeC-C), 3.88 (s, 6H, HMe-C), 2.36 (s, 6H, HMe). ¹³C NMR (126 MHz, CD₂Cl₂) δ/ppm 158.2 (C⁴), 154.7 (C⁶), 153.0 (C²), 152.4 (C⁸), 151.2 (C⁶), 149.3 (C⁴), 140.5 (C⁸), 138.6 (C⁴), 133.2 (C⁷), 126.9 (C⁵), 124.4 (C⁶), 128.7 (C⁷), 117.6 (C⁸), 105.1 (C⁵), 61.1 (CMe-C), 57.0 (COMe), 25.74 (CMe). ESI-MS m/z 735.2 [M – PF₆]⁺ (calc. 735.2). UV-VIS (see text). Satisfactory elemental analysis was not obtained.

DSC and external quantum efficiency (EQE) measurements

The DSCs were masked for measurements; the mask was made from a black-coloured copper sheet with an aperture of average area 0.06012 cm² (standard deviation = 1%) placed over the active area of the cell. The area of the aperture in the mask was smaller than the surface area of TiO₂ (0.36 cm²). Black tape was used to complete the masking of the cell. Performance measurements were made by irradiating the DSC from behind with a LOT Quantum Design LS0811 instrument (100 mW cm⁻² = 1 sun), and the simulated light power was calibrated with a silicon reference cell.

The external quantum efficiency (EQE) measurements were made using a Spe-Quest quantum efficiency setup (Rera Systems, Netherlands) operating with a 100 W halogen lamp (QTH) and a lambda 300 grating monochromator (Lot Oriel). The monochromatic light was modulated to 3 Hz using a chopper wheel (ThorLabs), and the cell response was amplified with a large dynamic range IV converter (CVI Melles Griot) and then measured with a SR830 DSP Lock-In amplifier (Stanford Research).

Results and discussion

Ligand syntheses and characterizations

We have previously described the synthesis of the anchoring ligand 1 from the corresponding tetraethyl ester.²² Deprotection of tetraethyl ((6,6'-dimethyl-[2,2'-bipyridine]-4,4'-dilyl)bis(1-phenylene))bis(phosphonate) is carried out using concentrated aqueous HCl followed by treatment with glacial acetic acid. This reaction takes 3 days, and we present here an alternative route involving treatment of the ester with Me₂SiBr which gives acid 1 in 58.6% yield within 24 hours.

The Kröhnke strategy²⁴ was used to prepare compounds 3–6, and the synthetic route is summarized in Scheme 4; a stoichiometric amount of 1-(2-oxopropyl)pyridinium chloride was combined with intermediate 3a, 4a, 5a or 6a. Ligand 3 has previously been prepared in 25% yield,²² but by using the Kröhnke method, we were able to isolate 3 in 79.5% yield. The base peak in the electrospray mass spectrum of each of 3–6 arose from the [M + H]⁺ and the isotope pattern matched that simulated. The stable isotope pattern matched that simulated. The ¹H and ¹³C NMR spectra of the ligands are

Electrodes were washed with EtOH, and then heated on a hot plate at 450 °C for 30 min to remove volatile organic impurities.

The working and counter-electrodes were combined with thermoplas hot-melt sealing foil (Solaronix Test Cell Gaskets, 60 μm) by heating while pressing them together. The electrolyte (LiI (0.1 M), I₂ (0.05 M), 1-methylbenzimidazole (0.5 M), 1-butyl-3-methylimidazolium iodide (0.6 M) in 3-methoxypropionitrile) was added to the device by vacuum backfilling through a hole in the hole electrode that was then sealed (Solaronix Test Cell Seals) and covered (Solaronix Test Cell Caps).
consistent with the asymmetric structures shown in Scheme 2 and were assigned using COSY, NOESY, HMQC and HMBC methods; the spectrum of ligand 5 is shown in Fig. 1a as a representative example. In the NOESY spectrum for 5, cross peaks between H\textsuperscript{C2} and H\textsuperscript{B5}, and between H\textsuperscript{C2} and H\textsuperscript{B5} allowed proton H\textsuperscript{C2} to be distinguished from H\textsuperscript{C3}; this was confirmed by a NOESY peak between H\textsuperscript{C3} and H\textsuperscript{OMe}; an H\textsuperscript{B5}–H\textsuperscript{Me(3H)O} NOESY cross peak distinguished H\textsuperscript{B5} from H\textsuperscript{B5}. Signals in the \textsuperscript{1}H NMR spectra of 3, 4 and 6 were assigned in a similar manner.

Copper(I) complexes

The homoleptic complexes [Cu(Lancillary)\textsubscript{2}][PF\textsubscript{6}] with Lancillary = 3–6 were prepared by reaction of [Cu(NCMe)\textsubscript{4}][PF\textsubscript{6}] with two equivalents of ligand and were isolated as dark red-orange solids in 71.2–90.0% yield. The highest mass peak in the electrospray mass spectrum of each complex corresponded to the [M – PF\textsubscript{6}]\textsuperscript{+} ion and showed a characteristic isotope pattern corresponding to the simulated pattern. The \textsuperscript{1}H and \textsuperscript{13}C NMR spectra of 3–6, 4 and 6 were assigned in a similar manner.

Solid state absorption spectra of TiO\textsubscript{2}-adsorbed copper(I)-containing dyes

The heteroleptic dyes [Cu(1)(3)]\textsuperscript{+}, [Cu(1)(4)]\textsuperscript{+}, [Cu(1)(5)]\textsuperscript{+}, [Cu(1)(6)]\textsuperscript{+}, [Cu(2)(3)]\textsuperscript{+}, [Cu(2)(4)]\textsuperscript{+}, [Cu(2)(5)]\textsuperscript{+} and [Cu(2)(6)]\textsuperscript{+} were assembled in a step-wise manner on transparent TiO\textsubscript{2} electrodes. Electrodes were soaked for 24 hours in a DMSO solution of anchoring ligand 1 or 2, followed by immersion for 3 days in a CH\textsubscript{2}Cl\textsubscript{2} solution of the respective homoleptic [Cu(Lancillary)\textsubscript{2}][PF\textsubscript{6}] complex (Lancillary = 3–6). After washing and
Table 1 Absorption maxima for [Cu(Lancillary)2][PF6] with Lancillary = 3–6 (CH2Cl2, 5 x 10−5 mol dm−3).

| Complex | λmax/nm (εmax/dm3 mol−1 cm−1) | MLCT |
|---------|-------------------------------|-------|
| [Cu(3)2][PF6] | 248 (53 700), 273 (65 000), 311 (38 300), 354 (6300) | 470 (10 800) |
| [Cu(4)2][PF6] | 257 sh (61 700), 276 (82 200), 308 sh (48 400), 353 (9800) | 467 (13 300) |
| [Cu(5)2][PF6] | 278 (58 300), 306 (49 000), 354 sh (15 400) | 468 (10 100) |
| [Cu(6)2][PF6] | 282 (49 200), 309 (44 600), 353 sh (15 800) | 470 (9300) |

* sh = shoulder; ε values are rounded to the nearest 100 dm3 mol−1 cm−1.

are consistent with a lower dye-loading on increasing the steric requirements of the anchoring ligand. By eye, the electrodes with adsorbed dyes [Cu(2)(3)]+ to [Cu(2)(6)]+ appear a more intense orange colour than those with [Cu(1)(3)]+ to [Cu(1)(6)]+; this is seen in the photographs of the electrodes shown in Fig. 4a. An electrode with N719 is shown in Fig. 4a for comparison. In Fig. 4b, the absorption spectra of TiO2 functionalized with [Cu(1)(3)]+ and [Cu(2)(3)]+ are compared with that of an electrode with adsorbed N719 and underline the fact that light-harvesting by the copper(i) dyes lacks contributions from the red-end of the visible region in particular.

DSC performances

DSCs were made by stepwise assembly of the dyes [Cu(1)(3)]+, [Cu(1)(4)]+, [Cu(1)(5)]+, [Cu(1)(6)]+, [Cu(2)(3)]+, [Cu(2)(4)]+, [Cu(2)(5)]+ and [Cu(2)(6)]+ on the photoanode (see Experimental section); after introduction of the I−/I3− electrolyte, the DSCs were sealed and were completely masked before measurements were made. To confirm reproducibility of performance parameters, two DSCs were assembled for each dye. Additional cells with anchor 2 were also made and performance parameters were the same within experimental error as those discussed in detail below; Fig. 5 and S1† show J–V curves for multiple DSCs containing [Cu(2)(3)]+, [Cu(2)(4)]+, [Cu(2)(5)]+ and [Cu(2)(6)]+. Measurements of the DSCs were made on the day the cells were made, then again one and seven days later. Tables 2 (for

Drying, the electrodes were placed in a tailor-made holder in the spectrophotometer and the absorption spectra recorded in transmission mode. Duplicate electrodes were used to validate the data, and Fig. 3a shows the spectra of one set of electrodes.

The four dyes with anchoring ligand 2 exhibit MLCT absorptions with λmax = 466–468 nm. Replacing the 6,6′-methyl groups by 6,6′-phenyl substituents on going from anchor 2 to 1 leads to a reduction in the intensity of the MLCT bands while gaining slightly at longer wavelengths (Fig. 3a and b). The data

**Fig. 6** \( J-V \) curves for DSCs containing the dyes [Cu(1)(Lancillary)]\(^+\) and [Cu(2)(Lancillary)]\(^+\) (Lancillary = 3–6) measured on the day the DSCs were assembled.

Firstly, we consider the effect of changing the 6,6′-substituents in the anchoring ligand. The data in Tables 2 and 3, and the \( J-V \) curves in Fig. 6 reveal that the dyes containing the 6,6′-diphenyl-substituted anchoring ligand 1 perform poorly with...
respect to those with the 6,6’-dimethyl-substituted anchor 2, both in terms of values of $J_{SC}$ and $V_{OC}$. The trend in values of $J_{SC}$ upon changing the anchoring ligand are corroborated by the external quantum efficiency (EQE) spectra shown in Fig. 7. Although use of the 6,6’-diphenyl-substituted 1 leads to a broad spectral response between 420 and 630 nm (Fig. 7), values of EQE$_{\text{max}}$ are <12% for [Cu(1)[$\text{Lancillary}$]]$^{+}$ ($\text{Lancillary} = 3$–$6$), compared to EQE$_{\text{max}}$ values in the range 41.8 to 49.4% ($\lambda_{\text{max}}$ = 470–480 nm) for [Cu(2)[$\text{Lancillary}$]]$^{+}$ ($\text{Lancillary} = 3$–$6$). The results are consistent with DSC parameters for [Cu(1)[$\text{N}^\text{N}$’N]’] $^{+}$ versus [Cu(2)[$\text{N}^\text{N}$’N]’] dyes where the bpy-based ancillary ligand contains 4-bromophenyl substituents in both the 4- and 4’- positions.$^{12}$ On the day of cell fabrication, DSCs containing anchor 2 with ancillary ligands 3–6 achieve overall efficiencies, $\eta$, of between 27.9 and 38.4% relative to that of the reference dye N719 set at 100% (Table 3); the efficiencies decrease somewhat over a period of a week, but remain ~30% that of N719 set at 100%. In contrast, use of the more sterically demanding anchor 1 results in relative efficiencies of $\approx$11.0%. 

Secondly, we focus on the dyes containing the 6,6’-dimethyl-substituted anchor 2. The performance parameters for DSCs containing [Cu(2)[$\text{4}$]’]$^{+}$ may be compared with those with the dye [Cu(2)[$\text{8}$]’]; ligand 8 is related to 4 as shown in Scheme 3. We have previously demonstrated$^{8,9}$ that the photoconversion efficiencies of DSCs with [Cu(2)[$\text{8}$]’] are $\approx$2.4%. However, because of the use of different light sources (Solaronix SolarSim 150 $^{8,9}$ and LOT Quantum Design LS0811 in the present work), efficiencies relative to N719 set at 100%$^{28}$ are more meaningful than absolute values of $\eta$ for comparative purposes. DSCs containing [Cu(2)[$\text{8}$]’] achieve relative efficiencies of 33.0% on the day of cell fabrication, compared with 27.9% and 28.6% for the two cells containing [Cu(2)[$\text{4}$]’].

The incorporation of the electron-releasing methoxy substituent in the 4-position of the bpy unit in 5 is beneficial, as expected in terms of the desirable ‘push–pull’ characteristics of a dye for an n-type DSC. Use of [Cu(2)[$\text{5}$]’] leads to enhanced values of $V_{OC}$ with respect to [Cu(2)[$\text{4}$]’] (Fig. S1† and 6). Overall, the efficiencies of DSCs containing [Cu(2)[$\text{5}$]’] are higher than those with [Cu(2)[$\text{6}$]’] and this can be understood in terms of the dominant +M effect of the 4-methoxy substituent being partially countered by the –I effects of the 3,5-dimethoxy groups. Data in Table 3 show that this trend is maintained over a week after the cells were assembled and that the gain in performance originates from enhanced $J_{SC}$. Although values of EQE$_{\text{max}}$ for DSCs with [Cu(2)[$\text{5}$]’] and [Cu(2)[$\text{6}$]’] are the same (Fig. 7), the EQE spectrum for the DSC with [Cu(2)[$\text{5}$]’] is appreciably extended towards the red-end of the spectrum, consistent with higher $J_{SC}$ values for cells sensitized with [Cu(2)[$\text{5}$]’]. An unexpected observation is that DSCs containing [Cu(2)[$\text{3}$]’] perform well, especially on the day of cell fabrication. The relatively high values of $J_{SC}$ (Table 3, Fig. S1† and 7) are an important contributing factor, and effective values of $V_{OC}$ are also achieved (Table 3, Fig. S1† and 6). Simple ancillary ligands such as 3 (Scheme 3) are often overlooked in a desire to design ‘push–pull’ dyes for the n-type semiconductor surface.$^{2}$ However, the present results suggest that such ancillary ligands deserve further exploration.

**Bleaching of the dyes and dye regeneration**

Table 3 shows that over a 7 day period after the DSCs were made, the cells containing [Cu(2)[$\text{Lancillary}$]]$^{+}$ ($\text{Lancillary} = 3$–$6$) exhibited stable photoconversion performances, whereas Table 2 reveals that the performances of cells with [Cu(1)[$\text{Lancillary}$]]$^{+}$ generally decayed. By eye, the red-orange colour of the photoanodes in the DSCs containing anchor 1 bleached. To investigate the process, solid-state absorption spectra of transparent FTO/TiO$_2$ electrodes functionalized with [Cu(1)[$\text{4}$]’] were recorded and then the electrodes were soaked 15 min in either a 3-methoxypropionitrile solution of Li$^+$ or in a solution of the standard $\Gamma$/$\Gamma_3^-$ electrolyte used for the DSCs. In both cases, the orange colour of the dye bleached (Fig. 8, left) and the MLCT band arising from the adsorbed dye decreased in intensity (Fig. 9), consistent with our previous proposal that bleaching is caused by attack at the copper(i) centre by $\Gamma^-$ ion.$^{12}$ The electrodes were then soaked in either MeCN solutions of

![Fig. 7 EQE spectra for DSCs containing the dyes [Cu(1)[$\text{Lancillary}$]]$^{+}$ and [Cu(2)[$\text{Lancillary}$]]$^{+}$ ($\text{Lancillary} = 3$–$6$) measured on the day the DSCs were made.](image1)

![Fig. 8 Photographs of electrodes used for the dye bleaching and regeneration tests.](image2)
confirmed by using multiple devices for each dye. Solid-state absorption spectra of adsorbed [Cu(1)\(\text{Lancillary}\)] and [Cu(2)\(\text{Lancillary}\)], and external quantum efficiency (EQE) spectra of DSCs containing these dyes show that use of the diphenyl-substituted 1 results in a broadened spectral response at lower energies compared to dyes with anchor 2. However, dye-loading is higher for [Cu(2)\(\text{Lancillary}\)] than for [Cu(1)\(\text{Lancillary}\)], and EQE\(_{\text{max}}\) is \(>41\%\) for [Cu(2)\(\text{Lancillary}\)] compared to \(<12\%\) for [Cu(1)\(\text{Lancillary}\)]. For all four ancillary ligands, use of anchor 2 rather than 1 leads to significantly higher J\(_{\text{SC}}\) values. For the series of [Cu(2)\(\text{Lancillary}\)] dyes, DSC measurements have been validated by using four different cells for each dye, and conclusions upheld by confirming DSC reproducibility. The photoconversion efficiencies of [Cu(2)\(\text{Lancillary}\)] dyes vary with \(\text{Lancillary}\) in the order 3 \(~5\) > 4 on the day of DSC assembly, and 5 > 6 > 4 after a week. The best performing DSCs achieve efficiencies of \(~37\%\) relative to N719 set at 100\%. DSCs containing the [Cu(1)\(\text{Lancillary}\)] dyes rapidly bleach, but the adsorbed dye can be regenerated on the electrode by reimmersion in dye baths containing [Cu(\(\text{Lancillary}\))\(\text{PF}_6\)] or [Cu(NCMe)\(\text{PF}_6\)] followed by \(\text{Lancillary}\). We are currently investigating dyes containing symmetrical analogues of 3, 5 and 6, as well as the effects of isomerization within the methoxyphenyl rings.

**Acknowledgements**

We gratefully acknowledge the financial support of the European Research Council (Advanced Grant 267816 LiLo), the Swiss National Science Foundation (Grant numbers 200020_144500 and 200020_162631) and the University of Basel. Dr Andreas M. Bünzli and Frederik J. Malzner are thanked for recording NMR and mass spectra, respectively.
