Biotransformation of ginsenosides \( R_{b1}, R_{g3} \) and \( R_{h2} \) in rat gastrointestinal tracts

Tianxiu Qian\(^1,2\) and Zongwei Cai*\(^1\)

**Abstract**

**Background:** Ginsenosides such as \( R_{b1}, R_{g3} \) and \( R_{h2} \) are major bioactive components of *Panax ginseng*. This *in vivo* study investigates the metabolic pathways of ginsenosides \( R_{b1}, R_{g3} \) and \( R_{h2} \) orally administered to rats.

**Methods:** High performance liquid chromatography-mass spectrometry (LC-MS) and tandem mass spectrometry (MS-MS) techniques, particularly liquid chromatography electrospray ionization mass spectrometry (LC-ESI-MS), were used to identify the metabolites.

**Results:** Six metabolites of \( R_{b1} \), six metabolites of \( R_{g3} \) and three metabolites of \( R_{h2} \) were detected in the feces samples of the rats. \( R_{h2} \) was a metabolite of \( R_{b1} \) and \( R_{g3} \), whereas \( R_{g3} \) was a metabolite of \( R_{b1} \). Some metabolites such as protopanaxadiol and monooxygenated protopanaxadiol are metabolites of all three ginsenosides.

**Conclusion:** Oxygenation and deglycosylation are two major metabolic pathways of the ginsenosides in rat gastrointestinal tracts.

**Background**

*Panax ginseng* (*Renshen*) is used in Chinese medicines to treat various conditions such as debility, ageing, stress, diabetes, insomnia and sexual inadequacy [1-3]. The major bioactive components of *P. ginseng* are O-glycosides of the triterpen dammarane saponins known as ginsenosides [4,5] which exhibit properties such as anti-inflammation and anti-tumor [6-8]. Over 80 ginsenosides have been isolated from *P. ginseng* [9]. \( R_{b1}, R_{g3} \) and \( R_{h2} \) are three major ginsenosides with various bioactivities.

\( R_{b1} \), which is the most abundant (0.22-0.62%) among all ginsenosides [5], protects against free radical damage, maintains normal cholesterol and blood pressure [10] and inhibits the induction phase of long-term potentiation by high frequency stimulation in the dentate gyrus of the brain [11]. \( R_{b1} \) also rescues hippocampal neurons from lethal ischemic damage [12] and delays neuronal death from transient forebrain ischemia *in vitro* [13]. \( R_{g3} \) is used as the major active component in an anti-tumor and anti-cancer drug in China [14]. The cytotoxicity of ginsenoside \( R_{g3} \) against tumor cells increases when \( R_{g3} \) is metabolized into \( R_{h2} \) or protopanaxadiol [15]. The metabolic transformation of \( R_{g3} \) into protopanaxadiol also increases the activity against *Helicobacter pylori*. Recently, *in vitro* biotransformation of ginsenosides was reported. The metabolites were identified by high-resolution tandem mass spectrometry. Degradation and bioconversion routes of the different ginsenosides at acidic (gastric) conditions and in the presence of intestinal microbiota were elaborated [16].

High performance liquid chromatography (HPLC) is a powerful chemical analysis technology that allows complex mixtures to be transformed into separated components. Mass spectrometry (MS) has progressed extremely rapidly during the last decade; especially in production, separation and ejection of ions, data acquisition and data reduction. Compared to other detectors, the advantages of the mass spectrometer are that in many cases it can provide absolute identification, not only structural information from the molecule under investigation but the molecular weight of the analyte.

Due to the specificity and sensitivity of LC-MS, especially in combination with MS-MS, it is powerful in identification of drug metabolites. Common
biotransformation, e.g., oxidative reactions (hydroxylation), conjugation reactions to produce sulphates, glucuronides, glutathiones or other conjugates, hydrolysis of esters and amides, and reduction reactions, can be evaluated from just the knowledge of the molecular mass of the metabolites. Combination of the molecular-mass and possible biotransformation products, predicted by computer-aided molecular modeling approaches, enables the confirmation of metabolic pathways. Further confirmation and/or structure elucidation of metabolites is possible using MS-MS methods [17]. The identification of the metabolites of antihistamine compounds is feasible by using thermospray LC-MS and LC-MS-MS [18,19]. The present study aims to investigate the biotransformation of ginsenosides Rb1, Rg3 and Rh2 orally administered to rats by using LC-MS and MS-MS.

Methods

Chemicals
Ginsenosides Rb1, Rg3 and Rh2 (purity >99%) were provided by the Chinese Medicine Laboratory, Changchun Institute of Applied Chemistry, Chinese Academy of Sciences, China. HPLC-grade methanol was purchased from Acros Organics (USA). A Mili-Q Ultra-pure water system (Millipore, USA) was used to provide water for all the experiments. Other chemicals (analytical grade) were purchased from Sigma (USA).

Administration of ginsenosides

Water soluble Rb1, Rg3 and Rh2 were administered to three groups (n = 3 in each group) of male Sprague Dawley rats (body weight 200-220 g; age 6-7 weeks) respectively at a dose of 100 mg/kg body weight with 2 ml dosing solution. The protocols of the animal study were fully complied with the University policy on the care and use of animals and with related codes of practice. The animal experiments were conducted with the licenses granted by Hong Kong Hygiene and Health Department. Rat feces samples were collected at such intervals: 0 to 120 hours for Rb1 (half-life 16.7 hours), 0 to 24 hours for Rg3 (half-life 18.5 minutes) and 0 to 48 hours for Rh2 (half-life 16 minutes)[20-22].

Feces sample preparation

Each feces sample of each rat was suspended in 150 ml of water and then extracted with n-butanol (100 ml × 3). The extract was dried and the residue was dissolved in 1 ml of methanol. After centrifugation at 12000 rpm for 20 minutes (Eppendorf Centrifuge 5415R, Hamburg, Germany), 2 μl of the supernatant was analyzed with LC-Ms and LC-MS-MS for the identification of the ginsenosides and their metabolites. The blank feces (baseline) were collected from the same Sprague Dawley rat prior to the administration of ginsenosides, prepared and analyzed with the same method as the experimental groups.

LC-ESI-MS analysis

HPLC separation was performed with a LC system coupled with an auto-sampler and a micro mode pump (HP1100, Agilent Technologies, USA). A reversed-phase column (Waters, Xterra MS-C8, 2.1 × 100 mm, 3.5 μm) was used to separate the ginsenosides and their metabolites. The auto-sampler was set at 10°C. Mobile phase consisted of two eluents: water (A) and methanol (B). Gradient elution was 40% B in 0-4 minutes, 40-90% B in 4-5 minutes, 90% B in 5-35 minutes, 90-40% B in 35-36 minutes and 40% B in 36-42 minutes at a flow rate of 100 μl/min. Effluent from the LC column was diverted to waste for the first 12 minutes following the injection, and then diverted to the MS ion source.

MS experiments were performed on a quadruple-time of flight (Q-TOF) tandem mass spectrometer API QSTAR Pulsar I (Applied Biosystems, USA). Negative or positive ion mode in electrospray ionization (ESI) was used to analyze ginsenosides and their metabolites in rat feces samples. The following parameters of the turboionspray for positive ion mode were used: ionspray voltage 5500 V, declustering potential 1 (DP1) 90 V, focusing potential (FP) 265 V and declustering potential 2 (DP2) 10 V, collision energy (CE) 55 eV for MS-MS analysis. For negative ion mode, the parameters were: ionspray voltage -4200 V, declustering potential 1 (DP1) -90 V, focusing potential (FP) -265 V and declustering potential 2 (DP2) 10 V, collision energy (CE) -60 eV for MS-MS analysis. For both positive and negative ion mode, the ion source gas 1 (GS1), gas 2 (GS2), curtain gas (CUR) and collision gas (CAD) were 20, 15, 25 and 3, respectively. The temperature of GS2 was set at 400°C.

Results and Discussion

Metabolites of Rb1, in rat feces

The parent Rb1 and direct oxygenated metabolites of Rb1 were not detected in the feces samples. These results suggested that Rb1 might have largely metabolized in the gastrointestinal tracts in rats. Six metabolites were detected in rat feces samples collected 0-120 hours after Rb1 was orally administered (Figure 1). The metabolites were detected from the LC-MS analyses and confirmed by the results from the LC-MS-MS experiments in positive ESI mode [18]. A total of four deglycosylated metabolites were identified, namely Rd, Rg5, Rh2 and protopanaxadiol (Figure 2). Analysis of [M + Na]+ ions (Figure 3) indicated that the metabolites shared similar MS-MS fragmentation pattern with the parent Rb1. The fragmentation patterns of the metabolites, produced from the [M + Na]+ ions at m/z 969, m/z 807, and m/z 645 respectively, were
Figure 1 Deglycosylated and oxygenated metabolic pathways of Rb₁ orally administered to rats.

Figure 4 Metabolic pathways of Rg3 orally administered to rats.
compared with that of Rb₁. The deglycosylated metabolites of Rb₁ showed the same fragment patterns as Rb₁, i.e. the glucose moiety and water were lost from the molecular ion and the corresponding sodium-adduct daughter ions at m/z 789 and m/z 203 for Rd, m/z 627 and m/z 365 for Rg₃, and m/z 465 and m/z 203 for Rh₂ were produced.

The deglycosylated metabolites were also confirmed by the LC-MS analysis of authentic standards of Rd, Rg₃, Rh₂ and protopanaxadiol. Moreover, the LC-MS-MS analysis indicated that these deglycosylated metabolites were subsequently oxygenated in digestive tracts. Thus, deglycosylation and subsequent oxygenation are the major metabolic pathways of orally administered Rb₁ in rats.

Figure 5 illustrates the proposed metabolic pathways of Rh₂ orally administered to rats.

Metabolites of Rg₃ in rat feces
Six metabolites were detected in rat feces samples collected 0-24 hours after Rg₃ was orally administered. The same LC-MS and MS-MS method as for Rb₁ was used to detect major deglucosylated and further oxygenated metabolites of Rg₃. The MS-MS results were similar to those for Rb₁, Rh₂ and protopanaxadiol as the deglycosylated products were also confirmed by reference standards. Figure 4 summarizes the major metabolites of Rg₃ detected in the rat feces samples and the metabolic pathway in rat gastrointestinal tracts. After the oral adminis-
turation, oxygenation and deglycosylation appeared to be the major metabolic pathways of ginsenosides. Metabolites were detected for the parent Rg3 and its deglycosylated metabolites including the mono- and deoxygenated products of protopanaxadiol.

Metabolites of Rh2 in rat feces

Three major metabolites were detected in rat feces samples collected 0-48 hours after Rh2 was orally administered. The LC-MS and MS-MS method in positive ESI mode was used to detect and confirm the metabolites respectively. Oxygenated products, such as mono-oxygenated protopanaxadiol, were also identified. Deglycosylation and oxygenation were the major metabolic pathways of Rh2. Figure 5 illustrates the proposed metabolic pathway of Rh2 in rat gastrointestinal tracts.

Conclusion

Oxygenation and deglycosylation are two major metabolic pathways of the ginsenosides in rat gastrointestinal tracts. Furthermore, Rh2 is a metabolite of Rb1 and Rg3, whereas Rg3 is a metabolite of Rb1. Some metabolites such as protopanaxadiol and mono-oxygenated protopanaxadiol are metabolites of all three ginsenosides.
