Supporting Information

ABSTRACT: New organometallic gold(III) and platinum(II) complexes containing iminophosphorane ligands are described. Most of them are more cytotoxic to a number of human cancer cell lines than cisplatin. Cationic Pt(II) derivatives 4 and 5, which differ only in the anion, Hg₂Cl₆₂⁻ or PF₆⁻ respectively, display almost identical IC₅₀ values in the sub-micromolar range (25–335-fold more active than cisplatin on these cell lines). The gold compounds induced mainly caspase-independent cell death, as previously reported for related cycloaurated compounds containing IM ligands. Cycloplatinated compounds 3, 4, and 5 can also activate alternative caspase-independent mechanisms of death. However, at short incubation times cell death seems to be mainly caspase dependent, suggesting that the main mechanism of cell death for these compounds is apoptosis. Mercury-free compound 5 does not interact with plasmid (pBR322) DNA or with calf thymus DNA. Permeability studies of 5 by two different assays, in vitro Caco-2 monolayers and a rat perfusion model, have revealed a high permeability profile for this compound (comparable to that of metoprolol or caffeine) and an estimated oral fraction absorbed of 100%, which potentially makes it a good candidate for oral administration.

INTRODUCTION

Cisplatin and the follow-on drugs carboplatin (paraplatin) and oxaliplatin (eloxatin) have been used to treat different cancers for the past 40 years.¹ However, their effectiveness is still hindered by clinical problems, including acquired or intrinsic resistance, a limited spectrum of activity, and high toxicity, leading to side effects.²,³ In the search for more effective and selective potential anticancer metallo-drugs,⁴ different approaches have been pursued, including the study of organometallic compounds. Evidence showing that organometallic compounds of platinum perform better than their non-organometallic derivatives was reported.⁵ In general, organometallic compounds are kinetically more inert and lipophilic than coordination metal complexes, which may offer opportunities in the design of anticancer metallo-drugs with improved properties. Several reviews on the anticancer activity of organometallic compounds from a number of different transition metals have appeared in the past 5 years.⁶–¹⁷

More specifically, gold(III)³,⁶ and platinum(II)¹⁴,¹⁸–²⁰ organometallic compounds have been studied as potential anticancer agents. A number of complexes containing the [Pt(COD)] fragment and different ligands, such as alkyls, alkynyls, and nucleosides, have been described.²¹–²³ Platinum COD alkynyl compounds showed high toxicity against HT-29 colon carcinoma and MCF-7 breast adenocarcinoma cell lines,²⁴,²⁵ while [PtMe(R-COD)L] compounds²⁶ with different ligands (halides, alkyl, aryl, alkynyl) revealed higher toxicity to

HeLa cells in comparison to that of cisplatin. In the case of gold(III), it is well known that pincer ligands containing carbon and nitrogen stabilize the metal center against reduction to gold(I) and gold(0) species in physiological media. The anticancer activities of cyclometalated gold(III) and platinum(II) compounds with bidentate C,N- or terdentate C,N,N-pincer ligands have been recently reviewed. Some cyclometalated gold(III) complexes based on C,N,N- and C,N,C-pincer complexes have displayed impressive anticancer activity in vitro and in vivo by a mode of action different from that shown by cisplatin. It has been proposed that, for these complexes, the presence of the σ(M–C) bond increases the stability of the compounds allowing the organometallic fragment to reach the cell unaltered. In addition, it has been postulated that in platinum compounds the presence of aromatic groups in the cyclometalated ligand might favor intercalative binding to DNA (π–π stacking), while the labile positions in the coordination sphere may favor covariant coordination for DNA as in cisplatin. Very recently, we have reported that nontoxic iminophosphorane or iminophosphane (IM) compounds containing a water-soluble phosphine (d) inhibit PARP-1 proteins. More recently, we have described a water-soluble ruthenium(II) IM compound (g in Chart 1) which has displayed high activity against a number of cancer cell lines in vitro. This compound was also highly active on MDA-MB-231 xenografts in mice, with an impressive tumor reduction (shrinkage) of 56% after 28 days of treatment (14 doses of 5 mg/kg every other day), with low systemic toxicity, quick absorption in plasma, and preferential accumulation in breast tumor tissues. In most cases (including some Pd(II) and Pt(II) derivatives), we have demonstrated that DNA is not the target for these compounds and that most complexes are highly active against cisplatin-resistant cancer cell lines, pointing to a mode of action different from that of cisplatin. We also evaluated the stability of the compounds in solution and proved that, for gold(III) and palladium(II) metal centers, cyclometalated C,N-IM compounds were more stable than those in which the IM ligand was N,N-coordinated.

In this context, we aimed to prepare cyclometalated IM compounds of gold(III) and platinum(II) in which the aryl group of the imino fragment is coordinated to the metal center (exo derivatives such as palladium compounds d and e in Chart 1) as opposed to an aryl group of the phoshine fragment (endo derivatives like a and b) in order to expand the range of phosphines incorporated into the final molecule to tune electronic/steric properties of the resulting complexes. The synthesis of the exo cyclometalated palladium starting material containing a water-soluble phosphine (d) was achieved by oxidative addition of Pd(0) to the C–Br bond in the IM bromide-containing ligand, a method that cannot be used to generate gold(III) and platinum(II) analogues.

We report here on the synthesis of novel exo cyclometalated C,N-IM compounds of gold(III) and platinum(II) containing the water-soluble phosphine 1,3,5-triaza-7-phenphaadamantane (PTA) and the synthesis of endo-C,N-IM compounds of platinum(II) derivatives never described before. All these complexes, along with the previously described exo derivative involving mitochondrial production of reactive oxygen species. We have studied the interaction of the IM metal compounds with (pBR322) DNA, calf thymus (CT) DNA, and human serum albumin (HSA). We have confirmed that some compounds (such as f) inhibit PARP-1 proteins. More recently, we have described a water-soluble ruthenium(II) IM compound (g in Chart 1) which has displayed high activity against a number of cancer cell lines in vitro. This compound was also highly active on MDA-MB-231 xenografts in mice, with an impressive tumor reduction (shrinkage) of 56% after 28 days of treatment (14 doses of 5 mg/kg every other day), with low systemic toxicity, quick absorption in plasma, and preferential accumulation in breast tumor tissues. In most cases (including some Pd(II) and Pt(II) derivatives), we have demonstrated that DNA is not the target for these compounds and that most complexes are highly active against cisplatin-resistant cancer cell lines, pointing to a mode of action different from that of cisplatin. We also evaluated the stability of the compounds in solution and proved that, for gold(III) and palladium(II) metal centers, cyclometalated C,N-IM compounds were more stable than those in which the IM ligand was N,N-coordinated.

In this context, we aimed to prepare cyclometalated IM compounds of gold(III) and platinum(II) in which the aryl group of the imino fragment is coordinated to the metal center (exo derivatives such as palladium compounds d and e in Chart 1) as opposed to an aryl group of the phoshine fragment (endo derivatives like a and b) in order to expand the range of phosphines incorporated into the final molecule to tune electronic/steric properties of the resulting complexes. The synthesis of the exo cyclometalated palladium starting material containing a water-soluble phosphine (d) was achieved by oxidative addition of Pd(0) to the C–Br bond in the IM bromide-containing ligand, a method that cannot be used to generate gold(III) and platinum(II) analogues.

We report here on the synthesis of novel exo cyclometalated C,N-IM compounds of gold(III) and platinum(II) containing the water-soluble phosphine 1,3,5-triaza-7-phenphaadamantane (PTA) and the synthesis of endo-C,N-IM compounds of platinum(II) derivatives never described before. RESULTS AND DISCUSSION

■

Synthesis and Characterization of the Cyclometalated Compounds. The synthesis of the exo cyclometalated gold(III) and platinum(II) compounds was based on the preparation of [Hg(Ph3P=N-CO-2-C6H4)Cl] by Nicholson et al.40 The C–H activation at the N-CO-Ph fragments takes place at a manganese center; thus, by transmetalation of the resulting cyclometalated iminophosphorane manganese compounds to HgCl2, the organomercury derivatives with PPh3, [Hg(Ph3P=N-CO-2-C6H4)Cl]40 or water-soluble phosphine PTA, [Hg(PTA=N-CO-2-C6H4)Cl]47 described by us, are obtained in high yields (Scheme 1).

Transmetalation reactions of [Hg(PR3=N-CO-2-C6H4)Cl]

(PR3 = PPh3; 40 PTA39) with NMe4[AuCl4] or [PtCl2(COD)] afforded previously described compound [Au(2-C6H4C(O)N=N=PPh3)Cl2] (1)40 and new cyclometalated exo-iminophosphorane complexes of gold(III) and platinum(II) of the type [Au(2-C6H4C(O)N=N=PTA)Cl2] (2) and [Pt(2-C6H4C(O)N=N=PTA)(COD)]2[Hg4Cl10] (3) (Scheme 2) in moderate to high yields.

The reaction of [Hg(PPh3=N-CO-2-C6H4)Cl] with [PtCl2(COD)] did not afford a pure cycloplatinated compound. Different synthetic conditions were tried, and in most cases abundant Pt(0) decomposition took place, while unreacted [Hg(PPh3=N-CO-2-C6H4)Cl] and PPh3=O were the observed products along with free COD. Longer refluxing times in polar solvents afforded small amounts (4–10%) of a possible cyclometalated product along with [Hg(PPh3=N-CO-2-C6H4)Cl] and PPh3=O.

New compounds 2 and 3 are obtained as air-stable yellow and white solids, respectively. Compound 2 is neutral, whereas the Pt(II) derivative 3 is cationic (2:1 ions), as confirmed by conductivity measurements (see Experimental Section). Compound 3 is only soluble in solvents such as DMSO or DME. We found that the COD ligand in 3 is immediately exchanged by DMSO molecules in DMSO-d6 solution at RT and that the new IM-cycloplatinated species did not change in DMSO-d6 over time (see Supporting Information (SI)). This was surprising since a COD ligand is not easily replaceable (usually requires thermal activation). The structures of these compounds have been proposed on the basis of elemental analysis, NMR and IR spectroscopy, and mass spectrometry (MS). Both compounds are soluble in mixtures of 1:99 DMSO:H2O at micromolar concentrations (relevant for biological studies).

The structure of 2 has been determined by an X-ray analysis, and it is very similar to that previously reported40 for compound [Au(2-C6H4C(O)N=N=PPh3)Cl2] (1),40 with very similar distances and angles. The molecular structure of 2 is depicted in Figure 1, while selected structural parameters are collected in Table 1.

The analysis confirms the square-planar arrangement around the gold(III) center with a bite angle of 81.68°. Like in other

C,N-IM cycoaurated complexes, $^{33,40−42}$ the Au−Cl(1) bond trans to the carbon is longer (2.3834(5) Å) than the Au−Cl(2) bond trans to the nitrogen (2.2798(5) Å) due to the higher trans influence of the C donor atom. As observed in compound 1, upon coordination to the gold there is an increase in both the C−C bond and the N−C bond lengths when compared to the uncoordinated ligand $^{33}$ (P−N: 1.626(3) Å in ligand, 1.6658 (18) Å in 2; N−C: 1.353(5) Å in ligand, 1.401(3) Å in 2). This effect is also observed in the IR spectra of compound 2, for which the band corresponding to the C=N bond appears at a lower frequency than that for the free ligand (1289 cm$^{-1}$ versus 1374 cm$^{-1}$). As described in the structure of compound 1, a decrease of the C=O bond length was observed (from 1.245(5) Å in the ligand to 1.213(3) Å in the cycoaurated complex).

We had described the biological activity of the endo-iminophosphorane compound $^{[Au(x^2-C,N-C,H_3)(PPh_3)=N-(C_5H_4)(C_5H_4)-2]Cl_2}$ and some of its cationic derivatives, like $[Au(x^2-C,N-C,H_3)(PPh_3)=N-(C_5H_4)(C_5H_4)-2]Cl_2$ (a in Chart 1), $^{35}$ but we had never synthesized Pt(II) endo compounds with the IM Ph-N=PPh$_3$ ligand. We carried out the reaction of $[Hg(C_5H_4)(PPh_3)=N-(C_5H_4)-2]Cl$ $^{41,42}$ with $[PtCl_2(COD)]$ and obtained (as in the case of the exo compound 3) a cationic species (4) with a mercury chloride-containing anion (in this case $[HgCl_4]$). In order to avoid the use of organomercury compounds and the presence of mercury in the resulting compound, a “greener” synthetic approach $^{44}$ based on transmetalation with an organogold(I)-phosphine compound $[Au(C_6H_4(PPh_3)=N-(C_5H_4)-2]-PPh_3]$, described previously, $^{45}$ was employed (Scheme 3).

We had used this mercury-free approach to obtain the endo gold(III) cyclometalated compound $[Au(x^2-C,N-C,H_3)(PPh_3)=N-(C_5H_4)-2]Cl_2$. The reaction proceeds much faster and in much milder conditions than that for the synthesis of 4 (25 min at RT in CH$_2$Cl$_2$ instead of 5 days in refluxing acetone), and compound 5 is obtained in moderate yield (58%). In order to avoid the formation of a neutral platinum(II) dimer with chloride bridges, $[Pt(C_5H_4)(PPh_3)=N-(C_5H_4)-2]Cl_2$ was observed while performing this reaction, NH$_4$PF$_6$ was added. In this way, we obtained compound 5, an analogue of cationic compound 4 with a mercury-free anion (PF$_6$). The structures of these compounds have been confirmed by elemental analysis, NMR (including $^{195}$Pt NMR) and IR spectroscopy, and MS studies. In this case the compounds do not exchange the COD ligand by DMSO molecules at RT in DMSO-$d_6$ solution as it happened for compound 3, which may have some connotations for the biological activity of the compounds. Compounds 4 and 5 are soluble in mixtures of 1:99 DMSO:H$_2$O solutions at micromolar concentrations (relevant for biological studies). A mercury-free analogue of compound 3 could not be obtained, since the preparation of the appropriate Au(I) transmetalation agent from the organomanganese compound (Scheme 1) was not successful.

The number of cycloplatinated iminophosphorane compounds described previously is limited to two examples of endo neutral derivatives, $[Pt(C_6H_4-2-PPh_3)=N-(C_5H_4)-2]Cl_2$ and $[Pt(x^2-C,N,N,C,H_3)(PPh_3)=N-(C_5H_4)-2]Cl_2$, in which the iminophosphorane fragment acts as a C,N,N-pincer ligand. In compounds 3−5, the IM ligand is cyclometalated in either an exo (3) or endo (4, 5) position, acting as a C,N,N-pincer ligand. The other two coordination positions for the Pt(II) center are occupied by the COD ligand. The molecular structure for compound 4 was determined by X-ray crystallography, confirming the proposed structure. The molecular structure of the cation in 4 is depicted in Figure 2, while selected structural parameters are collected in Table 2. A complete drawing of the crystal structure of 4, including the $[HgCl_4]$ anion and crystallization molecules, along with a more complete table of distances and angles are provided in the SI. The coordination geometry around the platinum atom is slightly distorted from square-planarity, with the C(1)−Pt(1)−N(1) angle of 85.31(9)$^\circ$ suggesting a rigid “bite” angle. The
Clearly visible along with coordinated DMSO). In the case of \( \text{Hg}_2\text{Cl}_6 \)\(^{2-} \), respectively, which re-exchanges the COD ligand by 31P\(^{1H}\) and 1H NMR spectroscopy. Due to the lack of solubility of 5 in mixtures of 1:99 DMSO:PBS in concentrations high enough to obtain a meaningful 31P\(^{1H}\) NMR spectrum, these experiments were performed in a 2:1 DMSO-\( \text{d}_6 \)/PBS-1X(D\( \text{d}_2 \)O) solution at pH 6 (see Experimental Section for details). In these conditions compound 5 is stable for at least 5 days, as can be observed by comparison with its \(^1\)H and 31P\(^{1H}\) NMR spectra in the same deuterated mixture at pH 7.4 (Figures S9–S12 in the SI).

**Biological Activity in Vitro. Anti-proliferative Studies In Vitro.** The anti-proliferative properties of the gold(III) and platinum(II) complexes 1–5 and ligand COD were assessed by monitoring their ability to inhibit cell growth using the MTT assay (see Experimental Section). The cytotoxicity activity of the compounds was determined in several human cancer cell lines, i.e., leukemia Jurkat-T, lung A549, prostate DU-145, pancreas MiaPaca2, and triple-negative breast MDA-MB-231, in comparison to cisplatin. The results are summarized in Table 3. The COD ligand is poorly cytotoxic in all tested cell lines (IC\(_{50} \) > 125 \( \mu \)M). The IM ligands are known to be poorly cytotoxic (IC\(_{50} \) > 100–500 \( \mu \)M in different cell lines). 33–38

Cyclometalated neutral gold(III) showed cytotoxicity similar to that of cisplatin, while compound 2 was less cytotoxic for all the studied cell lines, with the exception of the leukemia Jurkat cell line. We have found previously that replacement of PPh\(_3\) by PTA in IM-cyclometalated complexes decreases the cytotoxicity. 39 The IC\(_{50}\) value for Jurkat for compound 1 is very similar to that obtained for the neutral iminophosphorane endo derivative [Au\((x^2-C,N-C_6H_4(PPh_2\equiv N(C_2H_4))-2)\text{Cl}_2\)]\(^{32}\). Cationic gold(III) complexes containing IM ligands are more cytotoxic than neutral derivatives. 33,34 The cationic cyclometalated platinum compounds described here, 3 and especially 4 and 5, were considerably more cytotoxic than cisplatin in all the cell lines studied. 4 and 5 (same cation) display almost identical IC\(_{50}\) values, with the exception of A549 and MDA-MB-231, for which compound 4 containing the \( \text{Hg}_2\text{Cl}_6 \)\(^{2-} \) anion is twice as active than 5. The data indicate that cytotoxicity for these compounds comes mainly from the cationic platinum fragment.

In order to assess the compounds’ selectivity for cancerous cells with respect to normal cell lines, they were also screened for their anti-proliferative effects on the non-tumorigenic human embryonic kidney cells HEK293T. In most cases the cytotoxicity is comparable for the cancerous and HEK293T cell lines.

J. Med. Chem. 2015, 58, 3823–3841
cells. All compounds are more toxic to leukemia than to HEK293T cell lines (2–12 times), and compound 4 is more toxic to all the cell lines than to the HEK293T cell lines. The toxicity of mercury-free compound 5 to HEK293T is comparable to that in the human cancer cell lines. As HEK293T cell lines (immortalized cells) can display a higher sensitivity to chemicals, we measured the effect of compound 5 on human renal proximal tubular cells (RPTC). RPTCs in primary culture have been described as an in vitro model to study nephrotoxicity. The IC_{50} value (XTT assay 24 h; see SI for details) for 5 in this cell line was 2.77 ± 0.83 μM, making 5 more sensitive to cancerous cell lines than to RPTCs. In addition, we have described recently an IM ruthenium compound, [{η^6-p-cymene}Ru{(Ph_3P=N-CO-2-N-C_4H_4)-κ-N_3O}Cl]Cl, which displayed similar IC_{50} values in vitro for all the human cancer cell lines described above and HEK293T but which was very effective in vivo on MDA-MB-231 xenografts in NOD.CB17-Prkdc SCID/J mice while having low toxicity.

**Mechanism of Cell Death for the New Compounds.** The mechanism of cell death induced by mercury-free cytotoxic cycloplatinated compound 5 was analyzed in two cell lines of different origin: A549 lung carcinoma and Jurkat T-cell leukemia. Phosphatidyl serine exposure, plasma membrane damage, and nuclear morphology were assessed in both cell lines after treatment with 5. Caspase implication in the toxicity of 5 was studied using the general caspase inhibitor z-VAD-fmk. In A549 cells we found that z-VAD-fmk protected cells from 5 at doses up to 0.5 μM (Figure 3), inhibiting both phosphatidylserine exposure (annexin V binding) and plasma membrane permeabilization (7-ADD uptake). As expected, phosphatidylserine exposure was more dependent on caspase activity. At higher concentrations 7-AAD staining, but not annexin V binding, increased, suggesting that cell death was necrotic.

![Figure 3. Role of caspases on cell death induced by compound 5 in A595 cells. Cells were cultured for 24 h in the presence of 5 at indicated concentrations, alone (solid lines) or combined with the general caspase inhibitor z-VAD-fmk (dashed lines). Subsequently, phosphatidylserine exposure (triangles) and cell membrane permeabilization (squares) were analyzed by flow cytometry after staining with annexin V-DY634 and 7-AAD, respectively. Results are mean ± SD of two independent experiments with duplicates.](image)

![Figure 4. Caspase implication in mitochondrial effects of compound 5 in A549 cells. Cells were cultured for 24 h in the presence of compound 5 at the indicated concentrations, alone (solid line) or combined with the general caspase inhibitor z-VAD-fmk (dashed line). Then, transmembrane mitochondrial potential was analyzed by flow cytometry after cells were stained with the probe DiOC6(3). Results are mean ± SD of two independent experiments with duplicates.](image)

Jurkat cells were more sensitive to 5 than A549 cells, with an IC_{50} of 0.6 μM, even though this cell line does not express functional p53, discarding an essential role of this protein in the activity of compound 5. In these cells, the percentages of 7-AAD (Figure 5) and annexin V-positive (data not shown) cells were the same in every assay. High sensitivity of Jurkat cells was confirmed in short-term experiments, as we observed that 5 at 0.5 μM induced cell death in almost 100% of the cells even at 6 h. Caspase inhibition by z-VAD-fmk completely avoided cell death at 6 h. However, longer treatment with 5 induced both mitochondrial transmembrane potential, was analyzed, we also observed that caspase inhibition by z-VAD-fmk only partially reduced ΔΨ_m loss caused by 5 (Figure 4), further suggesting that compound 5 can induce caspase-dependent and caspase-independent cell death in A549 cells.

![Figure 5. Implication of caspases in cell death induced by compound 5 in Jurkat cells. Cells were treated with compound 5 for 6 or 24 h in the presence or in the absence of the general caspase inhibitor z-VAD-fmk. Membrane integrity was analyzed by flow cytometry after the cells were stained with 7-AAD, as indicated in the Experimental Section. Results are mean ± SD of two independent experiments.](image)
caspase-dependent and caspase-independent cell death (Figure 5).

Mitochondrial damage was also analyzed in Jurkat cells (Figure 6). At 24 h, treatment with 5 caused a decrease in ΔΨm in 80% of cells, compared to 32% in cells treated with 5 in the presence of the general caspase inhibitor z-VAD-fmk. In order to determine whether mitochondrial damage caused by 5 was irreversible and committed cells to death, cells were washed and resuspended in fresh medium. After a further 24 h incubation in fresh medium, ΔΨm collapse was observed in nearly 100% of cells (Figure 6). These results indicate that caspase inhibition only delays cell death in Jurkat cells, and 5 induces cell damage, leading to cell death independently of caspase activation. Thus, these experiments confirm that alternative caspase-independent cell death mechanisms are activated by this compound, as observed in A549 cells.

On the other hand, analysis of nuclear morphology indicated that 5 induced typical apoptotic features (chromatin condensation and fragmentation) that were prevented by z-VAD-fmk in both cell lines (Figure 7). However, some nuclei of cells treated with 5+z-VAD displayed an altered morphology when compared to controls. This morphology could be caused by necroptosis or AIF-mediated cell death.

Finally, we analyzed the implication of mitochondria in the toxicity of compound 5. We used Jurkat-shBak cells, obtained by RNAi of Bak. Since Jurkat cells do not express Bax, the Jurkat-shBak cell line constitutes a model of human leukemia cells deficient in the intrinsic (mitochondrial) pathway of apoptosis. A cell line transfected with a nonspecific shRNA was used as a control (Jurkat pLVTHM). As shown in Figure 8, Jurkat-shBak cells were less sensitive to 5 than control cells. However, high concentrations of 5 induced Bax/Bak-independent cell death in Jurkat-shBak cells, suggesting that this compound could be useful in the treatment of tumors with alterations in the intrinsic pathway of apoptosis.

We also analyzed the type of cell death for the cycloaurated exo compounds 1 and 2, the cycloplatinated exo compound 3,
and the cycloplatinated endo compound 4 (analogue of 5 containing the mercury anion Hg_2Cl_6^{2-}) in Jurkat cells in the presence or absence of z-VAD-fmk (caspase inhibitor). This analysis showed that the gold compounds 1 and 2 were less toxic than platinum complexes 3 and 4, as already indicated by the IC_{50} values (Table 3). Moreover, these results show that gold compounds 1 and 2 induced mainly caspase-independent cell death. We had found that iminophosphorane-organogold(III) endo compounds also activated caspase-independent pathways that lead to cell death, as the addition of z-VAD-fmk did not significantly reduce the percentage of annexin V+PE’ or PI’ in Jurkat cells treated with these derivatives. Thus, the behavior of iminophosphorane-organogold(III) (both endo and exo) compounds is basically the same and also similar to that of other cyclometalated gold(III) anticancer agents.

The toxicity for the cycloplatinated exo compound 3 (Figure 9) and for the endo compound 4, differing from 5 only in the anion (data not shown), was only partially dependent on caspase activity. At 24 h, 3 caused cell death in around 50% of total Jurkat cells, and caspase inhibition reduced this percentage to 25%. These data indicate that cycloplatinated compounds 3, 4, and 5 can activate alternative caspase-independent mechanisms of death. However, at short incubation times, cell death seems to be mainly caspase dependent (Figure 5), suggesting that the main mechanism of cell death for these compounds is apoptosis.

To summarize, from these initial mechanistic studies it seems clear that the cell death type for the most active mercury-free cycloplatinated compound 5 is mainly through caspase-dependent apoptosis but that 5 triggers caspase-independent cell death when apoptosis is blocked, pointing to a mode of action different from that of cisplatin.

**Lipophilicity and Permeability Assays.** The lipophilicity of the most active cycloplatinated compounds 4 and 5 was determined by calculating the partition coefficients (see Table 4 and Experimental Section) between n-octanol and phosphate buffer (pH 7.00). Partition coefficients have been used to predict the permeability of drugs since there is a good correlation between intestinal permeability and physicochemical parameters such as lipophilicity. We wanted to study the influence of the two different anions (Hg_2Cl_6^{2-}, 4, and PF_6^-) on the lipophilicity and permeability of these cationic cycloplatinated compounds.

Metoprolol was chosen as the reference compound for permeability since it is known that 95% of the drug is absorbed from the gastrointestinal tract. Thus, drugs that exhibit partition coefficients and human intestinal permeability values greater than or equal to the corresponding values for metoprolol are considered high-permeability drugs. Drugs with estimated partition coefficients and human intestinal permeability values less than the corresponding values for metoprolol are classified as low-permeability drugs. This type of correlation is a suitable source of information on the passive and also possible carrier-mediated absorption mechanism. From these data we can state that compound 5 is more lipophilic than 4 and metoprolol.

Subsequently, the permeabilities of cisplatin as commercialized parent compound, cycloplatinated 4 and 5 as test compounds, and metoprolol, cimetidine, and atenolol/Lucifer Yellow as reference compounds of high, intermediate, and low permeability, respectively, were determined using an in vitro cell model based on the measurement of the permeabilities of the compounds through Caco-2 monolayers and an in situ method by performing a rat perfusion assay. Results from the in vitro cell assay are shown in Figure 10 and data collected in Table 5, while the results in the rat model are depicted in Figure 11 and data collected in Table 6.

![Figure 9](image)

**Figure 9.** Jurkat cells were treated with DMSO (Control) or compound 1 (10 μM), 2 (20 μM), or 3 (10 μM) for 24 h, in the absence or in the presence of 50 μM z-VAD-fmk. Cell death was analyzed by annexin V-FITC binding and flow cytometry. Results are mean ± SD of two independent experiments.

![Figure 10](image)

**Figure 10.** Permeability values obtained from apical to basal (PAB) and from basal to apical (PBA) of cisplatin (at different concentrations), cycloplatinated 4 and 5, and permeability reference compounds metoprolol, cimetidine, and Lucifer Yellow at 20 μM in Caco-2 cells. Data correspond to the averaged values for three independent experiments.

![Table 4](image)

**Table 4. Partition Coefficients (Ratio n-Octanol:Phosphate Buffer) of Compounds 4 and 5 and Reference Metoprolol**

| Compound | P   | log P |
|----------|-----|-------|
| metoprol | 0.20±0.02 | −0.68 |
| 4        | 0.54±0.03 | −0.26 |
| 5        | 1.05±0.05 | 0.02  |

PAB is the value corresponding to the permeability from the apical to the basolateral chamber that simulates the permeability in the physiological sense from intestine to plasma. The PBA value corresponds to the permeability from the basolateral to apical chamber. This PBA value would be the hypothetical value for the permeability “from plasma to intestine”. Although the PBA value has no physiological
metoprolol is not a suitable drug for oral administration. 

The permeability of compound 4 is higher than that of atenolol, slightly higher than that of cimetidine, but lower than that of metoprolol. Compound 4 can be considered a compound of intermediate permeability. Compound 5 exhibits permeability higher than that of compound 4 and slightly higher than that of metoprolol, indicating that 5 is a highly permeable compound. Both compounds 4 and 5 display a much better absorption profile than cisplatin.

In addition, we have validated the relationship between Caco-2 cells’ permeability and oral fraction absorbed in our experimental system (represented in Figure 12) and previously used for fraction absorbed predictions. The permeabilities of cisplatin and derivatives 4 and 5 have been included in this correlation. The predicted oral fraction absorbed is more than 60% for compound 4 and almost 100% for compound 5, demonstrating its improved absorbability properties with respect to cisplatin. In the absence of solubility or dissolution limitations the absorption of these compounds would be almost complete; thus, with the adequate formulation strategy, they represent promising candidates for oral administration.

3. Reactivity with Biomolecules

Interactions with DNA. Since DNA replication is the key event for cell division, it is among the critically important targets in cancer chemotherapy. Most cytotoxic platinum drugs form strong covalent bonds with DNA bases. However, a variety of platinum compounds act as DNA intercalators upon coordination to the appropriate ancillary ligands. It has been reported that most gold(III) compounds display reduced affinity for DNA, although there are a number of Au(III) porphyrin complexes and cyclometalated species with C,N,C-pincer ligands that act as DNA intercalators and, in some cases, as DNA topoisomerase inhibitors. We investigated in some cases, as DNA topoisomerase inhibitors.

**Table 5. Permeability Values Obtained by the Caco-2 Cell Monolayers Assay**

| compound (20 μM) | \( P_{\text{eff}} \) (cm/s) | SD |
|------------------|--------------------------|----|
| 5 | 5.44 \times 10^{-7} | 4.66 \times 10^{-7} |
| 4 | 4.62 \times 10^{-4} | 3.54 \times 10^{-6} |
| metoprolol | 2.71 \times 10^{-3} | 5.00 \times 10^{-6} |
| cimetidine | 1.86 \times 10^{-5} | 3.71 \times 10^{-7} |
| Lucifer Yellow | 1.90 \times 10^{-7} | 4.98 \times 10^{-8} |

“Metoprolol, cimetidine, and Lucifer Yellow were used as model compounds of high, medium, and low oral permeability, respectively. Data correspond to the averaged values for three independent experiments.

**Table 6. Absorption Rate Coefficients, \( K_{\text{at}} \), and Permeability Values Obtained from in Situ Rat Assays**

| compound | \( K_{\text{at}} \) (h–1) | SD | \( P_{\text{eff}} \) (cm/s) | SD |
|----------|-----------------|----|--------------------------|----|
| cisplatin | ND | – | ND | – |
| 5 | 2.12 \± 0.22 | 5.50 \± 10^{-3} | \± 5.40 \× 10^{-6} |
| metoprolol | 2.30 \± 0.15 | 5.40 \± 10^{-3} | \± 3.54 \× 10^{-6} |
| cimetidine | 1.68 \± 0.12 | 3.97 \± 10^{-3} | \± 3.04 \× 10^{-6} |
| atenolol | 0.22 \± 0.02 | 5.19 \± 10^{-7} | \± 4.72 \× 10^{-7} |

“Metoprolol, cimetidine, and atenolol were used as model compounds of high, medium, and low oral permeability, respectively. Data correspond to values of six independent experiments. ND = not detectable. 520 μM. 5100 μM.
the interactions of the gold(III) and platinum(II) complexes with plasmid pBR322 DNA and with CT DNA and directly compared them to the same interactions of cisplatin.

**Interaction of Complexes 1−5 with Plasmid pBR322 DNA.** To gain insight into the nature of the compound−DNA interactions, gel electrophoresis studies were performed with gold(III) (1 and 2) and platinum(II) (3−5) complexes on plasmid (pBR322) DNA (Figure 13). Plasmid pBR322 presents two main forms, OC (open circular or relaxed) and CCC (covalently closed or supercoiled), which display different electrophoretic mobility. Changes in the electrophoretic mobility of any of the forms upon incubation of the plasmid with a compound are usually interpreted as evidence of interaction. Generally, a drug that induces unwinding of the CCC form will produce a retardation of the electrophoretic mobility, while coiling of the OC form will result in increased mobility. Figure 13 shows the effect of cisplatin and compounds 1−5 on plasmid pBR322 DNA after incubation at 37 °C for 20 h in Tris-HCl buffer at different drug/DNA ratios. As previously reported, cisplatin is able to both increase and decrease the mobility of the OC and the CCC forms, respectively.59 Treatments with increasing amounts of compounds 1, 2, 4, and 5 do not cause any shift for either form, consistent with no unwinding or other changes in topology under the chosen conditions. Treatment with increasing amounts of 3 retards the mobility of the faster-running supercoiled form (Form I), especially at higher molar ratios. In order to understand the interaction of 3 with DNA, platinum compounds 3−5 were incubated with CT DNA and analyzed by CD.

**Interaction with Calf Thymus DNA.** More detailed DNA conformational changes can be detected by means of CD spectroscopy. CD spectral technique is very sensitive to diagnose alteration on the secondary structure of DNA that results from DNA−drug interactions. A typical CD spectrum of CT DNA shows two conservative bands, a positive band with a maximum at 273 nm due to base stacking and a negative band with a minimum at 242 nm due to helicity, characteristic of the B conformation of DNA.60 Therefore, changes in the CD signals can be assigned to corresponding changes in DNA secondary structures. In addition, it is known that simple groove binding or electrostatic interaction of small molecules causes little or no alteration to any of the CD bands when compared to major perturbation induced by covalent binding or intercalation. The most dramatic changes in CT DNA can be observed with compound 3 (Figure 14A). Upon addition of
increasing amounts of the complex, the intensity of the positive band diminishes, and a new negative band at 287 nm and a positive band at 251 nm appear. This type of modification in the CD spectrum of CT DNA is characteristic of conformational changes in DNA from B, the usual right-handed form of DNA, to Z, the left-handed form of DNA.61 The formation of left-handed helix of Z-form DNA structure is similar to the transition seen in purely electrostatic environments such as those provided by HgCl₂ and Hg(ClO₄)₂.62 Thus, the presence of [Hg₄Cl₁₀]²⁻ anion in compound 3 seems to lead to the conformational change from B form to Z form.

Organoplatinum endo compound 4 leads to minor changes of the B-type CD spectrum (Figure 14B) with slight decrease of the intensities of the positive bands and with no modification in the negative region. This points out that the DNA binding of complex 4 induces conformational changes including conversion from a more B-like to a more C-like structure within the DNA molecule.64 This conformational change is indicative of a non-intercalative mode of binding of the complex and offers support that the complex is either groove binding or electrostatic in nature, and the change might be due to the lower concentration of Hg²⁺ released by compound 4, [Hg₂Cl₆]³⁻ (compared to that released by compound 3 containing a [Hg₄Cl₁₀]²⁻ anion), although the influence of the more lipophilic Pt(II) cation in compound 4, could not be completely ruled out.

Finally, as shown in Figure 14C, compound 5 does not lead to any modification of the DNA bands with respect to untreated CT DNA, suggesting that the interaction of compound 5 with CT DNA is almost nonexistent. This is in agreement with our findings described above about the influence of the mercury anion in compounds 3 and 4 in their interaction with CT DNA since the anion in compound 5 is PF₆⁻.

In conclusion, the experiments of DNA–drug interactions have shown that compound 3 induces the formation of left-handed helix of Z-form DNA through strong electrostatic interactions and compound 4 appears to be either groove binding or electrostatic in nature. This is supported by two main facts: (1) retardation of the plasmid (pBR322) DNA electrophoretic mobility observed only for compound 3 and (2) results obtained by CD spectroscopy. Importantly, the mercury-free cationic organoplatinum compound 5 does not seem to interact with DNA, indicating that, as for other transition-metal IM complexes, its antitumor properties are due to non-DNA-related mechanisms/factors.

Interactions with Human Serum Albumin. HSA is the most abundant carrier protein in plasma and is able to bind a variety of substrates, including metal cations, hormones, and most therapeutic drugs. It has been demonstrated that the distribution, the free concentration, and the metabolism of various drugs can be significantly altered as a result of their binding to this protein.67 HSA possesses three fluorophores, namely tryptophan (Trp), tyrosine (Tyr), and phenylalanine (Phe) residues, with Trp214 being the major contributor to the intrinsic fluorescence of HSA. This Trp fluorescence is sensitive to the environment and binding of substrates, as well as changes in conformation that can result in quenching (either dynamic or static).

Thus, the fluorescence spectra of HSA in the presence of increasing amounts of the compounds 1–5 and cisplatin were recorded in the 300–450 nm range upon excitation of the tryptophan residue at 295 nm. The compounds caused a concentration-dependent quenching of fluorescence without changing the emission maximum or the shape of the peak, as seen in Figure 15A for compound 3. All these data indicate an interaction of the compounds with HSA. The fluorescence data were analyzed by the Stern–Volmer equation (Figure 15B).
While a linear Stern–Volmer plot is indicative of a single quenching mechanism, either dynamic or static, the positive deviation observed in the plots of $F_0/F$ versus $[Q]$ of compounds 2–4 (Figure 15C) suggests the presence of different binding sites in the protein with different binding affinities. Of note, a similar behavior was observed in the case of coordination iminophosphorane complexes of $d^6$ metals, for which we also reported a concentration-dependent fluorescence quenching.\textsuperscript{35–39} On the other hand, the Stern–Volmer plot for complexes 1 and 5 shows a linear relationship (Figure 15D), suggesting the existence of a single quenching mechanism, most likely dynamic, and a single binding affinity. The Stern–Volmer constants for complexes 1 and 5 are 4.58×10$^6$ and 3.67×10$^6$ M$^{-1}$, respectively.

In general, higher quenching by the iminophosphorane complexes was observed compared to that of cisplatin under the chosen conditions, most likely due to the faster reactivity of our compounds with HSA, as compared to cisplatin.

**CONCLUSIONS**

We have reported on the synthesis and anticancer properties of cyclometalated neutral gold(III) and cationic platinum(II) derivatives containing iminophosphorane ligands. Most compounds are more cytotoxic to a number of human cancer cell lines than cisplatin. The gold compounds induced mainly caspase-independent cell death, as previously described for related cyclometalated iminophosphorane compounds. Cyclometalated compounds 3, 4, and 5 also activate caspase-independent mechanisms of death. However, at short incubation times cell death seems to be mainly caspase dependent, suggesting that the main mechanism of cell death for these compounds is apoptosis. The most promising candidate is the mercury-free lipophilic cationic cyclometalated compound 5. This derivative is much more active (25–300-fold) than cisplatin against a number of cancer cell lines while being less toxic on human proximal tubular cell lines. These facts, along with the lack of interaction observed for 5 with plasmid (pBR322) and CT DNA, point to a mode of action different from that of cisplatin. Permeability studies of 5 by two different assays, in vitro Caco-2 monolayers and a rat perfusion model, have revealed its high permeability profile (comparable to that of metoprolol or caripropril) and an estimated oral fraction absorbed of 100%, which potentially makes it a good candidate for oral administration. The results described for 5 and those recently reported for a ruthenium–iminophosphorane compound highly active in vivo against breast cancer,\textsuperscript{39} warrant further advanced preclinical studies with selected organometallic iminophosphorane compounds. The work described in this paper supports the idea of nontoxic iminophosphorane molecules are excellent ligands for the synthesis of organometallic compounds of $d^6$ and $d^8$ metals (especially cationic species) with relevant anticancer properties, high permeability, and, in some cases, water-solubility.

**EXPERIMENTAL SECTION**

All manipulations involving air-free syntheses were performed using standard Schlenk-line techniques under a nitrogen atmosphere or in a glovebox (MBraun MOD system). Solvents were purified by use of a PureSolv purification unit from Innovative Technology, Inc. The phosphine substrates TPA and PPh$_3$ were purchased from Sigma-Aldrich, [Mn$_2$(CO)$_{10}$] and [PtCl$_2$(COD)] were purchased from Strem Chemicals, and Na/Hg were purchased from Fisher Scientific and used without further purification. Compounds [PbCH$_3$Mn(CO)$_3$]$^{3+}$ and [Hg(2-C$_6$H$_4$C(O)N=Ph)Cl]$^{2-}$ were reported by methods. The purity of the compounds, based on elemental analysis, is ≥99.5%. NMR spectra were recorded on a Bruker AV400 instrument ({}$^1$H NMR at 400 MHz, {}$^{13}$C NMR at 100.6 MHz, {}$^{31}$P NMR at 161.9 MHz, \textsuperscript{195}Pt NMR at 85.7 Hz). Chemical shifts (δ) are given in ppm using CDCl$_3$ or DMSO-$d_6$ as solvent, unless otherwise stated. Elemental analyses were performed on a PerkinElmer 2400 CHNS/O analyzer, Series II. High-resolution electrospray ionization (HR-ESI) and matrix-assisted laser desorption/ionization (MALDI) mass spectra were obtained on an Agilent analyzer or a Bruker analyzer. Conductivity was measured in an Oakton pH/conductivity meter in acetone solution (10$^{-4}$ M). X-ray collection was performed at room temperature (RT) using graphite-monochromated and 0.5 mm MonoCap-collimated Mo K$_\alpha$ radiation (λ = 0.71073 Å) with the ω scan method. CD spectra were recorded using a Chirascan CD spectrometer equipped with a thermostated cuvette holder. Electrophoresis experiments were carried out in a Bio-Rad Mini subcell GT horizontal electrophoresis system connected to a Bio-Rad Power Pac 300 power supply. Photographs of the gels were taken with an Alpha Innotech FluorChem 8900 camera. Fluorescence intensity measurements were carried out on a PTI-QM-4/206 SE spectrophotometer (PTI, Birmingham, NJ) with right angle detection of fluorescence using 1 cm path length quartz cuvette.

**Synthesis**

[Pt(2-C$_6$H$_4$C(O)N=Ph)Cl]$^2$ (2). [Hg(2-C$_6$H$_4$C(O)N=Ph)Cl]$^2$ (0.15 g, 0.06 mmol), [MNE$_3$](AuCl)$_3$ (0.12 g, 0.2 mmol), and [MNE$_3$]Cl (0.035 g, 0.32 mmol) were stirred at RT in CH$_2$Cl$_2$ (15 mL) for 1 day in a foil-covered flask. The solvent was removed under reduced pressure. The fraction containing compound 2 was then extracted from the solid residue with CHCl$_3$ (3 × 10 mL), and the resulting yellow solution was filtered through Celite. The volume was reduced (<3 mL), and upon addition of EtO (20 mL) a pale yellow solid was precipitated. This solid was finally isolated by filtration and dried in vacuo. Yield: 0.15 g (93%). Anal. Calc. for C$_{23}$H$_{16}$N$_2$O$_4$AuCl: C, 21.72; H, 2.58; N, 4.72. ESI-MS: m/z 507.04 (100%, [M+Cl]$^-$); δ 507.04 (s), 1H NMR (CDCl$_3$): δ $^\text{H}$: 7.86 (s, 2-Hg), 7.70 (s, 3-Hg), 7.09 (s, 4-Hg), 7.43 (s, 5-Hg) ppm. IR (cm$^{-1}$): 1152 (ν$_S$), 1384 (ν$_S$), 1598 (ν$_S$), 1684 (ν$_S$), 2860 and 2950 (ν$_S$) cm$^{-1}$. Mass spectrum: m/z 507.04 (100%, [M + Cl]$^-$).

[Pt(2-C$_6$H$_4$C(O)N=Ph)Cl]$^2$(3). The synthesis of organometallic compounds of $d^6$ and $d^8$ metals (comparable to that of metoprolol or carvedilol) makes it a good candidate for oral administration. The results described for 5 and those recently reported for a ruthenium–iminophosphorane compound highly active in vivo against breast cancer, warrant further advanced preclinical studies with selected organometallic iminophosphorane compounds. The work described in this paper supports the idea of nontoxic iminophosphorane molecules are excellent ligands for the synthesis of organometallic compounds of $d^6$ and $d^8$ metals (especially cationic species) with relevant anticancer properties, high permeability, and, in some cases, water-solubility.
solvent was removed under reduced pressure. The final product was extracted with CH₂Cl₂ and the resulting solution filtered through Celite, giving a light yellow solution. The solution was concentrated (<3 mL), and upon addition of Et₂O (20 mL) the final product was precipitated as a white solid, isolated by filtration, and dried in vacuo.

Yield: 0.20 g (72%). Anal. Calcd for C₆₄H₆₂N₂P₂Cl₆Pt₂Hg₂: C (85.35); H, 3.21; N, 1.30. Found: C, 85.34; H, 3.26; N, 1.32.

**Cell Culture, Inhibition of Cell Growth, and Cell Death Analysis.** METT Toxicity Assays. For toxicity assays, cells (5 × 10⁴ for Jurkat cells and 10⁵ for adherent cell lines) were seeded in flat-bottom 96-well plates (100 µL/well) in complete medium. Adherent cells were allowed to attach for 24 h prior to addition of cisplatin or tested compounds. Compounds were added at different concentrations in triplicate. Cells were incubated with cisplatin or compounds for 24 h, and then cell proliferation was determined by a modification of the MTT-reduction method. Briefly, 10 µL/well of MTT (5 mg/mL in PBS) was added, and plates were incubated for 1–3 h at 37 °C. Finally, formazan crystal was dissolved by adding 100 µL/well 0.1% Triton X-100 and gently shaking. The optical density was measured at 570 nm using a 96-well multispecimen autoreader (ELISA).

**Cell Death Analysis.** Apoptosis/necrosis hallmarks of cells treated with compound 5 were analyzed by measuring mitochondrial membrane potential, plasma membrane integrity, and exposure of phosphatidylserine. Cells were treated with different concentrations and at different incubation times as indicated in figure legends. In some experiments the general caspase inhibitor z-VAD-fmk was added at 50 µM 1 h before compounds. For mitochondrial membrane potential determination, cells (2.5 × 10⁴ in 200 µL) after treatment with 5 were incubated at 37 °C for 15 min in medium containing 2 mM DIOC₆(3) (Molecular Probes). Phosphatidylserine exposure was quantified by labeling cells with annexin V-phycoerythrin (Invitrogen) after treatment with 5. Annexin V was added at a concentration of 0.5 µg/mL in Annexin Binding Buffer (ABB), and cells were incubated at room temperature for 15 min. Plasma membrane integrity was evaluated by staining with 7-aminoactinomycin D (7-AAD, Immunostep). At the end of the treatment with 5, cells were incubated for 15 min in 200 µL of PBS containing 50 µg/mL 7-AAD. In all cases, cells were diluted to 1 mL with ABB or phosphate buffered saline (PBS) to be analyzed by flow cytometry (FACSscan, BD Bioscience, San Jose, CA).

**Permeability Determinations.** Cell Culture and Transport Assays. Caco-2 cells were grown in Dulbecco's Modified Eagle's Medium containing t-glutamine, fetal bovine serum, and penicillin-streptomycin. To obtain cells, monolayers of 250 000 cells/cm² were seeded on each well with polycarbonate membrane with 4.2 cm² area. Plates were incubated at standard conditions of 37 °C, 95% humidity, and 5% CO₂ until confluence. After 19–21 days, the integrity of each cell monolayer was evaluated by measuring the trans-epithelial electrical resistance (TEER). Values ranging 500–750 Ω·cm² were considered appropriate.

Transport studies were performed using an orbital environmental shaker at constant temperature (37 °C) and agitation rate (50 rpm).

Hank's balanced salt solution (HBSS) supplemented with HEPES was used to fill the receiver chamber and to prepare the drug solution placed in the donor chamber. Four samples of 200 µL each were taken from the receiver chamber side at predefined times (15, 30, 60, and 90 min) and replaced with the same volume of fresh buffer. Moreover, two samples of the donor side were taken at the beginning and the end of the experiment. The amount of compound in cell membranes and inside the cells was determined at the end of the experiments in order to check the mass balance, and the percentage of compound retained in the cell compartment was always less than 5%.

Transport studies were performed in both directions, from apical-to-basal (A-to-B) and from basol-to-apical (B-to-A) sides. The volume of donor compartment was 2 mL in A-to-B direction and 3 mL in B-to-A direction.

**Analysis of the Samples.** Samples were analyzed by HPLC using a 5 µm, 4 × 200 mm Novapack C18 column. Components of cisplatin and compound 5 were analyzed with UV detection (λ = 240 nm). The mobile phase was 95:5 acetonitrile-water, with a flow rate of 1 mL/min, and the injected sample volume was 50 µL. Samples of compound 5 were analyzed similarly but using a UV detector at λ = 215 nm and a mobile phase of 80:20 acetonitrile:water.

**Data Analysis.** The apparent permeability coefficient was calculated following the equation:

\[
\frac{dC}{dt} = \frac{Q}{A} \left( C_{in} - C_{out} \right)
\]
Samples of the perfusate were taken every 5 min for 30 min. Then the entire intestine was restored into the abdominal cavity. The drug solutions were prepared freshly each day at pH 7.4: 9.2 g of NaCl, 0.34 g of KCl, 0.19 g of CaCl2·2H2O per liter was used to condition the intestinal mucosa prior to the experiments. A cleaning solution (Solution A) was prepared by the use of a stopcock type valve. Under this setup, the catheter was tied up at both intestinal ends and connected to a glass syringe via a stopcock. First, 50 mL of cleaning solution (Solution A) was used to flush out the content of the intestinal lumen due to the remaining cleaning solution, the adsorption to the membrane, and the loading process in the enterocyte. So, the intercept, \( C_0 \), is lower than the perfusion concentration. The quasi-steady-state is achieved in the membrane when this process is finished. Under these conditions, the disappearance of the compound from the lumen can be considered as a first-order process during the sampling time interval. For these reasons, only the concentrations obtained after 5 min were used for regression analysis. In order to obtain good prediction data, water re-absorption correction was introduced for the concentration calculations.

The intestinal permeability values were calculated taking into account the relationship between \( k_d \) and \( P_{app} \): 

\[
P_{app} = \left( k_d \frac{R}{d}\right) / 2
\]

where \( R \) is the radius of the intestinal segment, calculated as area/volume ratio. The effective intestinal permeabilities (\( P_{app} \)) of the tested compounds (means of at least of three animals) were used as indexes of the absorption effectiveness.

**Interaction of Compounds 1–5 and Cisplatin with Plasmid (pBR322) DNA by Electrophoresis (Mobility Shift Assay).** First, 10 \( \mu l \) aliquots of pBR322 plasmid DNA (20 \( \mu g/mL \)) in buffer (5 mM Tris-HCl, 50 mM NaClO4, pH 7.39) were incubated with different concentrations of the compounds 1–5 (in the range 0.25–2.0 metal complex:DNAbp) at 37 °C for 20 h in the dark. Samples of free DNA and cisplatin–DNA were prepared as controls. After the incubation period, the samples were loaded onto 1% agarose gel. The samples were separated by electrophoresis for 1.5 h at 80 V in Tris-acetate/EDTA buffer (TAE). Afterward, the gel was stained for 30 min with a solution of GelRed Nucleic Acid stain.

**Interaction of Compounds 3–5 and Cisplatin with Calf Thymus DNA by Circular Dichroism.** Stock solutions (5 mM) of each complex were freshly prepared in water prior to use. The right volume of those solutions was added to 3 mL samples of an also freshly prepared solution of CT DNA (195 \( \mu M \)) in Tris-HCl buffer (5 mM Tris-HCl, 50 mM NaClO4, pH 7.39) to achieve molar ratios of 0.1, 0.25, 0.5, and 1.0 drug/DNA. The samples were incubated at 37 °C for a period of 20 h. All CD spectra of DNA and of the DNA–drug adducts were recorded at 25 °C over a range 220–330 nm and finally corrected with a blank and noise reduction. The final data are expressed in molar ellipticity (mildidegrees).

**Interaction of Compounds 1–5 and Cisplatin with Human Serum Albumin by Fluorescence Spectroscopy.** A solution of each compound (8 mM) in DMSO was prepared, and 10 aliquots of 2.5 \( \mu L \) were added successively to a solution of HSA (10 \( \mu M \)) in phosphate buffer (pH 7.4) to achieve final metal complex concentrations in the range 10–100 \( \mu M \). The excitation wavelength was set to 295 nm, and the emission spectra of HSA samples were recorded at room temperature in the range of 300–450 nm. The fluorescence intensities of all the metal compounds, the buffer, and the DMSO are negligible under these conditions. The fluorescence was measured 240 s after each addition of compound solution. The data were analyzed using the classical Stern–Volmer equation, \( F_0/F = 1 + K_{sv}[Q] \).

### ASSOCIATED CONTENT

#### Supporting Information

Crystallographic data for compounds 2 and 4, including complete drawing of the structure and table of selected distances and angles for compound 4; stability of compounds 1–5 by \( ^{31}P\{^1H\} \) spectroscopy in DMSO-\( d_6 \) solution; selected \( ^1H \) and \( ^{31}P\{^1H\} \) NMR spectra for compounds 1–5 in DMSO-\( d_6 \); stability of compound 5 in DMSO-\( d_6 / PBS \) mixtures at \( pH \) 7.4 and \( pH \) 6 over time; stability of compounds 4 and 5 in DMSO/PBS (1:99) determined by vis–UV. The Supporting Information is available free of charge on the ACS Publications website at DOI: 10.1021/acs.jmedchem.5b00427.
Research at Brooklyn College was supported by a grant from the National Cancer Institute (NCI), 1SC1CA182844 (M.C.), and a grant from the National Institute of General Medical Sciences (NIGMS), SC2GM082307 (M.C.). The Spanish authors thank the Ministerio de Economía y Competitividad project, SAF2010-1490 (I.M.), for support, and the Ministerio de Ciencia/Universidad Miguel Hernandez for a Ph.D. fellowship, FPU AP2010-2372 (V.M.-S.). A.S. thanks the AECC (Asociación Española Contra el Cáncer) for a fellowship. We thank Mr. Tomer Madar (Brooklyn College undergraduate student at the time) for the initial preparation of compound 4 and Benedita T. Elie (Brooklyn College-Graduate CUNY Ph.D. student) for testing the IC50 of 5 in RPTC cell lines.

ABBREVIATIONS USED

ABB, Annexin Binding Buffer; CD, circular dichroism; COD, cyclooctadiene; CT, calf thymus; DMSO, dimethyl sulfoxide; HSA, human serum albumin; HBSS, Hank’s balanced salt solution; HEPEES, 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid; IM, iminophosphorane; ITC, isothermal titration calorimetry; MTT, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide; PARP-1, Poly(ADP-ribose) Polymerase-1; PBS, phosphate buffered saline; PTA, 1,3,5-triaza-7-phosphaadamantane; RPTC, renal proximal tubular cells; TAE, Tris-acetate/EDTA buffer; TEER, trans-epithelial electrical resistance; T-Jurkat, human acute lymphoblastic leukemia cells; T-Jurkat sh Bak, human acute lymphoblastic leukemia cells which do not express the Bak gene; XTT, 2,3-bis-(2-methoxy-4-nitro-5-sulfophenyl)-2H-tetrazolium-5-carboxanilide.
