Abstract

We show on the example of the discrete heat equation that for any given discrete derivative we can construct a nontrivial Leibniz rule suitable to find the symmetries of discrete equations. In this way we obtain a symmetry Lie algebra, defined in terms of shift operators, isomorphic to that of the continuous heat equation.
1 Introduction

Lie point symmetries were introduced by Sophus Lie for solving differential equations. They turn out to provide one of the most efficient methods for obtaining exact analytical solutions of partial differential equations [1]–[3]. This essentially continuous method has been recently extended to the case of discrete equations [4]–[6].

Let us write a general difference equation, involving, for notational simplicity, one scalar function \( u(x) \) of \( p \) independent variables \( x = (x_1, x_2, \ldots, x_p) \) evaluated at a finite number of points on a lattice. Symbolically we write

\[
E(x, T^a u(x), T^{b_i} \Delta_{x_i} u(x), T^{c_{ij}} \Delta_{x_i} \Delta_{x_j} u(x), \ldots) = 0, \tag{1.1}
\]

where \( E \) is some given function of its arguments,

\[
T^a u(x) := \left\{ T^{a_1} T^{a_2} \cdots T^{a_p} u(x) \right\}_{a_i = m_i}, \quad a = (a_1, a_2, \ldots, a_p), \quad i = 1, 2, \ldots, p, \tag{1.2}
\]

with \( a_i, m_i, n_i \) fixed integers \( (m_i \leq n_i) \), and

\[
T^{a_i} u(x) = u(x_1, x_2, \ldots, x_{i-1}, x_i + a_i \sigma_i, x_{i+1}, \ldots, x_p), \tag{1.3}
\]

(the other shift operators \( T^{b_i}, T^{c_{ij}} \) are defined in a similar way), \( \Delta_{x_i} \) is a difference operator which in the continuous limit goes into the derivative and \( \sigma_i \) is the positive lattice spacing in the uniform lattice of the variable \( x_i \) \( (i = 1, \ldots, p) \).

The simplest extension of the continuous case is when the symmetry transformation which leaves the equation on the lattice invariant depends just on \( u(x) \) and not on its shifted values, what was called intrinsic point transformations [4]. In this case the whole theory goes through but the resulting transformations are somehow trivial and provide often not very interesting solutions.

In Ref. [7] it has been proved that the intrinsic transformations can be extended for linear equations by considering symmetries where the transformed function \( \tilde{u}(x) \) depends not only on the old \( u(x) \) and \( x \) but also on the function \( u \) in shifted points \( T^{a_i} u(x) \) on the lattice.

The results presented in [7] where obtained considering the difference operator

\[
\Delta_{x_i} \equiv \Delta^+_{x_i} = \frac{T_{x_i} - 1}{\sigma_i}. \tag{1.4}
\]

This difference operator is the simplest one which, when \( \sigma_i \to 0 \), goes into the standard right derivative with respect \( x_i \).

Obviously, more general definitions of the difference operator can be introduced and one would like to be able to prove that the obtained symmetries are independent on the discretisation of the difference operator one is considering. Among the possibilities, let us mention

\[
\Delta^-_{x_i} = \frac{1 - T^{-1}_{x_i}}{\sigma_i}, \tag{1.5}
\]
corresponding to the left derivative, and the symmetric derivative (which goes into the derivative with respect to \( x_i \) up to terms of order \( \sigma_i^2 \))

\[
\Delta_{x_i}^s = \frac{T_{x_i} - T_{x_i}^{-1}}{2\sigma_i}.
\]  

(1.6)

Using the techniques of approximate differentiation \[8\] one could write more complicated formulas for difference operators which, however, are out of the scope of this letter.

In the following we will show that by a nontrivial definition of the Leibniz rule we can construct symmetries for any difference operator. Section 2 is devoted to review the Lie group formalism for difference equations. In Section 3 we apply it to the case of the discrete heat equation using the discrete derivatives (1.5)–(1.6), finding difficulties in the case (1.6). In Section 4 we show via examples how one can introduce in a consistent way the Leibniz rule and use this result to obtain determining equations equivalent to those for the standard discrete derivatives (i.e., \( \Delta_{x_i}^\pm \)). This fact shows that we get different representations of the same symmetry group. In the Conclusions we sketch how to write the determining equations when one uses a generic difference operator by using the corresponding Leibniz rule obtained with our approach.

2 Lie symmetries of difference equations

Among the different algebraic methods for calculating the symmetries of discrete equations \[5\]–\[10\] we will make use in this paper of the approach presented in Ref. \[10\], based on the formalism of evolutionary vector fields \[1\].

For a difference equation of order \( N \) like that given in (1.1) the infinitesimal symmetry vectors in evolutionary form, which in the continuous limit go over to point symmetries, take the general expression

\[
X_e \equiv Q \partial u = \left( \sum \xi_i(x, T^a u, \sigma_x, \sigma_t) T^b \Delta_{x_i} u - \phi(x, T^c u, \sigma_x, \sigma_t) \right) \partial u,
\]  

(2.1)

with \( \xi_i(x, T^a u, \sigma_x, \sigma_t) \) and \( \phi(x, T^c u, \sigma_x, \sigma_t) \) functions which in the continuous limit go over to \( \xi_i(x, u) \) and \( \phi(x, u) \), respectively.

The vector fields \( X_e \) generate the symmetry group of the discrete equation (1.1), whose elements transform solutions \( u(x) \) of the equation into solutions \( \tilde{u}(x) \). The \( N \)-th prolongation of \( X_e \) must verify the invariance condition

\[
pr^N X_e E|_{E=0} = 0.
\]

(2.2)

The group generated by the prolongations also transforms solutions into solutions, and \( \Delta_{x_i} u, \Delta_{x_j} \Delta_{x_i} u, \ldots \) (up to order \( N \)) into the variations of \( \tilde{u} \) with respect to \( x_i \). The formula of \( pr^N X_e \) is given by

\[
pr^N X_e = \sum_a T^a Q \partial T^a u + \sum_{b_i} T^{b_i} Q^{x_i} \partial T^{b_i} \Delta_{x_i} u + \sum_{c_{ij}} T^{c_{ij}} Q^{x_i x_j} \partial T^{c_{ij}} \Delta_{x_i} \Delta_{x_j} u + \ldots
\]  

(2.3)
The summations in (2.3) are over all the sites present in (1.1), \( Q^x, Q^{x,x_j}, \ldots \) are total variations of \( Q \), i.e.,

\[
Q^x = \Delta^T_{x_i} Q, \quad Q^{x,x_j} = \Delta^T_{x_i} \Delta^T_{x_j} Q, \quad \ldots
\]

(2.4)

where the partial variation \( \Delta^T_{x_i} \) is defined by

\[
\Delta^T_x f(x, u(x), \Delta_x u(x), \ldots) = \frac{1}{\sigma} \left[ f(x + \sigma, u(x), (\Delta_x u)(x), \ldots) - f(x, u(x), \Delta_x u(x), \ldots) \right], \quad x = x_i,
\]

(2.5)

and the total variation \( \Delta^T_{x_i} \) by

\[
\Delta^T_x f(x, u(x), \Delta_x u(x), \ldots) = \frac{1}{\sigma} \left[ f(x + \sigma, u(x + \sigma), (\Delta_x u)(x + \sigma), \ldots) - f(x, u(x), \Delta_x u(x), \ldots) \right], \quad \forall x = x_i.
\]

(2.6)

The symmetries of the equation (1.1) are given by equation (2.2). From it we get the determining equations for \( \xi_i \) and \( \phi \) as the coefficients of linearly independent expressions in the discrete derivatives \( T^a \Delta_{x_i} u, T^b \Delta_{x_i x_j} u, \ldots \).

The Lie commutators of the vector fields \( X_e \) are obtained by commuting their first prolongations and projecting onto the symmetry algebra \( G \), i.e.,

\[
[X_{e1}, X_{e2}] = [pr^1 X_{e1}, pr^1 X_{e2}]|_G
= \left( Q_1 \frac{\partial Q_2}{\partial u} - Q_2 \frac{\partial Q_1}{\partial u} + Q_1^{x_i} \frac{\partial Q_2}{\partial u_{x_i}} - Q_2^{x_i} \frac{\partial Q_1}{\partial u_{x_i}} \right) \partial_u,
\]

(2.7)

where the \( \partial u_{x_i} \) terms disappear after projection onto \( G \).

The formalism presented above is very complicated and if the system is nonlinear it is almost impossible to get a result since the number of terms to consider is a priori infinite. The situation is simpler in the case of linear equations for which we can use a reduced Ansatz. We assume that the evolutionary vectors (2.1) have the form

\[
X_e = \left( \sum_i \xi_i(x, T^a, \sigma_x, \sigma_t) \Delta_x u - \phi(x, T^a, \sigma_x, \sigma_t) u \right) \partial_u.
\]

(2.8)

Now the vector fields \( X_e \) can be written as \( X_e = (\hat{X} u) \partial_u \), i.e.,

\[
\hat{X} = \sum_i \xi_i(x, T^a, \sigma_x, \sigma_t) \Delta_{x_i} - \phi(x, T^a, \sigma_x, \sigma_t).
\]

(2.9)

The operators \( \hat{X} \) may span a subalgebra of the Lie symmetry algebra (see Ref. [10]).

### 3 Discrete heat equation

Let us consider the equation

\[
(\Delta_t - \Delta_{xx}) u(x) = 0,
\]

(3.1)
which is a discretisation of the heat equation. As the equation is linear we can consider an evolutionary vector field of the form

\[ X_e \equiv Q \partial_u = (\tau \Delta_t + \xi \Delta_x u + f u) \partial_u, \quad (3.2) \]

with \( \tau, \xi \) and \( f \) arbitrary functions of \( x, t, T_x, T_t, \sigma_x \) and \( \sigma_t \). As \( T_x \) and \( T_t \) are operators not commuting with \( x \) and \( t \), respectively, \( \tau, \xi \) and \( f \) are operator valued functions.

Since equation (3.1) is a second order difference equation it is necessary to use the second prolongation. The determining equation is

\[ \Delta_t^T Q - \Delta_x^T Q \big|_{\Delta_x u = \Delta_t u} = 0, \quad (3.3) \]

which explicitly reads

\[ \Delta_t (\xi \Delta_x u) + \Delta_t (\tau \Delta_x u) + \Delta_t (f u) - [\Delta_x (\xi \Delta_x u) + \Delta_x (\tau \Delta_x u) + \Delta_x (f u)] \big|_{\Delta_x u = \Delta_t u} = 0. \quad (3.4) \]

We had no need to give the explicit form of the operator \( \Delta \) to get equation (3.4). Only when developing expression (3.4) we need to apply Leibniz rule and, hence, the results will depend from the given definition of the discrete derivative.

### 3.1 Symmetries in the right (left) discrete derivative case

Choosing as in Ref. [7, 10] the derivative \( \Delta^+ \) and consequently the Leibniz rule

\[ \Delta^+ (fg) = \Delta^+ (f) T g + f \Delta^+ g \quad (3.5) \]

we obtain the following set of determining equations

\[
\begin{align*}
\Delta^+_t \tau &= 0, \\
(\Delta^+_t \tau) T_t - 2(\Delta^+_x \xi) T_x &= 0, \\
(\Delta^+_t \xi) T_t - (\Delta^+_x \xi) T^2_x - 2(\Delta^+_x f) T_x &= 0, \\
(\Delta^+_t f) T_t - (\Delta^+_x f) T^2_x &= 0,
\end{align*} \quad (3.6)
\]

by equating to zero the coefficients of \( \Delta_x u, \Delta_t u, \Delta_x u \) and \( u \), respectively. The solution of (3.6) gives

\[
\begin{align*}
\tau &= t^{(2)} \tau_2 + t \tau_1 + \tau_0, \\
\xi &= \frac{1}{2} x (\tau_1 + 2 t \tau_2) T_t T^{-1}_x + t \xi_1 + \xi_0, \\
f &= \frac{1}{4} x^{(2)} \tau_2 T^2_t T^{-2}_x + \frac{1}{2} t \tau_1 T_t + \frac{1}{2} t \xi_1 T_t T^{-1}_x + \gamma,
\end{align*} \quad (3.7)
\]

where \( \tau_0, \tau_1, \tau_2, \xi_0, \xi_1 \) and \( \gamma \) are arbitrary functions of \( T_x, T_t \) and of the spacings \( \sigma_x \) and \( \sigma_t \), and \( x^{(n)}, t^{(n)} \) are the Pochhammer symbols given by, for instance,

\[
x^{(n)} = x(x - \sigma_x) \ldots (x - (n - 1) \sigma_x). \quad (3.8)
\]
By a suitable choice of the functions \( \tau_i, \xi_i, \) and \( \gamma \) we get the following symmetries

\[
\begin{align*}
P_0 &= (\Delta_t u) \partial_u, & (\tau_0 = 1) \\
P_1 &= (\Delta_x u) \partial_u, & (\xi_0 = 1) \\
W &= u \partial_u, & (\gamma = 1) \\
B &= (2tT_t^{-1} \Delta_x u + xT_x^{-1} u) \partial_u, & (\xi_1 = 2T_t^{-1}) \\
D &= (2tT_t^{-1} \Delta_t u + xT_x^{-1} \Delta_x u + \frac{1}{2} u) \partial_u, & (\tau_1 = 2T_t^{-1}, \gamma = \frac{1}{2}) \\
K &= (t^2T_t^{-2} \Delta_t u - \sigma_t tT_t^{-2} \Delta_t u + t\sigma_x T_x^{-1} \Delta_x u \\
&\quad + \frac{1}{4} x^2 T_x^{-2} u - \frac{1}{4} \sigma_x xT_x^{-2} u + \frac{1}{2} tT_t^{-1} u) \partial_u, & (\tau_2 = T_t^{-2})
\end{align*}
\]

that close into a 6–dimensional Lie algebra which is isomorphic to the symmetry algebra of the continuous heat equation.

A second choice for the discrete derivative is \( \Delta^- \) and now the Leibniz rule becomes

\[
\Delta^-(fg) = \Delta^- (f) T^{-1} g + f \Delta^- g
\]

(3.10)

This gives the same results (3.7) and (3.9) provided we make the substitution \( T \rightarrow T^{-1} \).

### 3.2 Symmetries in the symmetric discrete derivative case

Next let us consider the case of the symmetric derivative \( \Delta^s \). It seems natural to propose the following Leibniz rule

\[
\Delta^s (fg) = \Delta^s (f) T^{-1} g + (T f) \Delta^s g.
\]

(3.11)

In this case taking as before coefficients of the different discrete derivatives of \( u \) (\( \Delta_t u, \Delta_x u, \Delta_x u \) and \( u \), respectively) the determining equations are

\[
\begin{align*}
T_t \tau - T_x^2 \tau &= 0, \\
T_t \xi - T_x^2 \xi - 2(T_x \Delta_x \tau) T_x^{-1} &= 0, \\
(\Delta_x^s \tau) T_t^{-1} + (T_t f) - 2(T_x \Delta_x \tau) T_x^{-1} - (\Delta_x \tau) T_x^{-2} - T_x^2 f &= 0, \\
(\Delta_x \xi) T_t^{-1} - (\Delta_x \xi) T_x^{-2} - 2(T_x \Delta_x f) T_x^{-1} &= 0, \\
(\Delta_x^s f) T_t^{-1} - (\Delta_x^s f) T_x^{-2} &= 0.
\end{align*}
\]

(3.12)

Note that there is one equation (the first one, associated to \( \Delta_t u \)) more that in the two previous cases. This implies that the solution of such equations (3.12) is just

\[
\tau = \tau_0, \quad \xi = \xi_0, \quad f = f_0,
\]

(3.13)

with \( \tau_0, \xi_0, \) and \( f_0 \) are arbitrary functions of \( T_x, T_t \) and of the spacings \( \sigma_x \) and \( \sigma_t \).

Obviously, in this last case our naive approach does not allows us to recover the whole symmetry algebra of the heat equation (3.3). In fact, we will show in next Section that the decomposition of equation (3.4) into equations (3.12) via Leibniz rule (3.11) is not the most appropriate one.
4 Leibniz rule and symmetries with symmetric derivatives

Let us consider a formal way to get Leibniz rule in the continuous case which is easily extendible to the case of discrete derivatives. This result will allow us to get the symmetries of a discrete equation independently of the discrete derivative used.

Starting from the well known result \([\partial_x, x] = 1\) by algebraic methods we get that \([\partial_x, f(x)] = f'(x)\) (at least for analytic functions). Consequently, the Leibniz rule \(\partial_x(fg) = fg' + f'g\) can be derived.

Now, let us consider the commutator with the differential operator substituted by a difference one. By direct computation we have

\[
[\Delta_{\pm}^x, x] = T_{\pm}^{-1}, \quad [\Delta_s^x, x] = \frac{T_x + T_x^{-1}}{2}. \tag{4.1}
\]

By introducing a function \(\beta_x = \beta(T_x)\) we can always rewrite the commutation relations (4.1) as

\[
[\Delta_x, x\beta_x] = 1. \tag{4.2}
\]

Let us note that \(\Delta_x \beta_x = \beta_x \Delta_x\) and \(\Delta_t \beta_x = \beta_x \Delta_t\).

For the standard left and right derivatives \(\Delta_{\pm}^x\) we easily find that \(\beta_x = T_{\pm}^{-1}\), and we get that

\[
[\Delta_{\pm}^x, f(x)\beta_{\pm}^x] = \left(\Delta_{\pm}^x f(x)\right) \beta_{\pm}^x. \tag{4.3}
\]

From this last expression we recover Leibniz rules (3.5) and (3.10).

For the symmetric discrete derivative \(\Delta_s^x\) we obtain the formal expression

\[
\beta_s^x = 2(T_x + T_x^{-1})^{-1}, \tag{4.4}
\]

and

\[
[\Delta_s^x, f(x)\beta_s^x] = \left(\Delta_s^x f(x)\right) T_x \beta_s^x + \left(T_x^{-1} f(x) - f(x)\right) \beta_s^x \Delta_s^x. \tag{4.5}
\]

From relation (4.5) we get the Leibniz rule

\[
\Delta_s^x (f(x)g(x)) = f(x)\Delta_s^x g(x) + \left[\frac{1}{\sigma_x}((T_x^{-1} - 1) f(x))(T_x - \beta_x^{-1})\right. \\
+ \left(\Delta_s^x f(x)\right) T_x] g(x). \tag{4.6}
\]

Let us note that expression (4.6) looks very different from (3.10).
Formula (4.9) allows us to write down the determining equations (3.4) as

\[(1 - T_x^{-1})\tau) T_x^{-1} + ((T_x - 1)\tau) T_x = 0,\]

\[\frac{1}{2\sigma_t} \left[ ((1 - T_t^{-1})\tau) T_t^{-1} + ((T_t - 1)\tau) T_t \right] - \frac{1}{\sigma_x} \left[ ((1 - T_x^{-1})\xi) T_x^{-1} + ((T_x - 1)\xi) T_x \right] = 0,\]

\[\frac{1}{2\sigma_t} \left[ ((1 - T_t^{-1})\xi) T_t^{-1} + ((T_t - 1)\xi) T_t \right] - \frac{1}{4\sigma_x^2} \left[ ((1 - T_x^{-1})^2\xi) T_x^{-2} + 2((T_x + T_x^{-1} - 2)\xi) + ((T_x - 1)^2\xi) T_x^2 \right] = 0,\]

\[\frac{1}{2\sigma_t} \left[ ((1 - T_t^{-1})f) T_t^{-1} + ((T_t - 1)f) T_t \right] - \frac{1}{4\sigma_x^2} \left[ ((1 - T_x^{-1})^2f) T_x^{-2} + 2((T_x + T_x^{-1} - 2)f) + ((T_x - 1)^2f) T_x^2 \right] = 0,\]

obtained as coefficients of \(\Delta_x u, \Delta_t u, \Delta_x u \text{ and } u\), respectively. So, we get the same number of equations as in the cases of the standard discrete derivatives \(\Delta^\pm\).

The solution of eqs.(4.7) is given by

\[\tau^s = t^{(2)}\tau_2 + t\tau_1 + \tau_0,\]

\[\xi^s = \frac{1}{2} x \left( 2t\tau_2 + \tau_1 + \sigma_t T_t^{-1}\beta^s \tau_2 \right)(\beta^s)^{-1}\beta^s + t\xi_1 + \xi_0,\]

\[f^s = \frac{1}{4} x^{(2)}\tau_2(\beta^s)^2(\beta^s)^{-2} + \frac{1}{4} x\xi_1(\beta^s)^{-1} + \frac{1}{4} x\sigma_x\tau_2 T_t^{-1}(\beta^s)^3(\beta^s)^{-2} + \frac{1}{2} t\tau_2(\beta^s)^{-1} + f_0,\]

where \(\tau_2, \tau_1, \tau_0, \xi_1, \xi_0\) and \(f_0\) are arbitrary functions of \(T_x, T_t, \sigma_x\) and \(\sigma_t\).

From (4.8) and (3.2) we obtain, with a suitable choice of \(\tau_2, \tau_1, \tau_0, \xi_1, \xi_0\) and \(f_0\), the following symmetries

\[P_0^u = (\Delta_x^u) \partial_u, \quad (\sigma_0 = 1)\]

\[P_1^u = (\Delta_x^u) \partial_u, \quad (\sigma_0 = 1)\]

\[W^u = u \partial_u, \quad (f_0 = 1)\]

\[B^u = (2t\beta^u_1 \Delta_x^u + x\beta^u_x) \partial_u, \quad (\xi_1 = 2\beta^u_t)\]

\[D^u = (2t\beta^u_1 \Delta_x^u + x\beta^u_x \Delta_x^u + \frac{1}{2} u) \partial_u, \quad (\tau_1 = 2\beta^u_t, f_0 = \frac{1}{2})\]

\[K^u = (\frac{1}{2} (\beta^u_t)^2 - t\beta^u_1 \Delta_t^u) \Delta_t^u + tx\beta^u_1 \beta^u_x \Delta_x^u \partial_u, \quad (\tau_2 = \beta^u_t, \tau_1 = \sigma_1 \beta^u_t - \sigma_1^2 \beta^u_1 \Delta_x^u)\]

They close the same 6-dimensional Lie algebra generated by the operators (3.9). The above result deserves some comments. First, there appear functions \(\beta^u_1(\beta^u_x)\) of \(T_t(T_x)\) that can only be understood as infinite series developments. Therefore, some of the above symmetries (4.9) have not a local character in the sense that they are not polynomials in \(T_t \pm 1, T_x \pm 1\). Although such symmetries give rise to the classical symmetries in the limit \(\sigma_x \to 0, \sigma_t \to 0\), one of them (\(K\)) also includes surprisingly a term in \((\Delta_t)^2\) (which vanishes in the continuous limit since it has a factor \(\sigma_1^2\)).
5 Conclusions

Analysing the different Leibniz rules used in Sections 3 and 4, we see that when we get the correct result the Leibniz rule must have the form

$$\Delta_x (f(x)g(x)) = f(x)\Delta_x g(x) + D_x(f(x))g(x),$$  \hspace{1cm} (5.1)

where $D_x$ is a function of $T_x$, $\beta_x$ and $\sigma_x$ (we should have written $D_x(f(x); T_x, \beta_x, \sigma_x)$, with $\beta_x$ given by eq. (4.2), but for the sake of shortness we will simply write $D_x(f)$, and similarly for $D_t(f)$). Once we have chosen a particular discrete derivative $\Delta_x$ we can write the explicit expression of $D_x$. In particular, for $\Delta_x^\pm$ and $\Delta_x^s$ their corresponding $D_x(f)$ functions are

$$D_x^\pm(f) = (\Delta_x^\pm(f))(\beta_x^\pm)^{-1} = (\Delta_x^\pm(f))T_x^\pm,$$

$$D_x^s(f) = \frac{1}{\sigma_x}((T_x^{-1}-1)f)(T_x-(\beta_x^s)^{-1}) + (\Delta_x^s f) T_x$$

$$= ((T_x^{-1}-1)f) \Delta_x^s + ((\Delta_x^s f) T_x]$$

$$= \frac{1}{2\sigma_x}[(1-T_x^{-1})f) T_x^{-1} + ((T_x - 1)f) T_x].$$  \hspace{1cm} (5.2)

Using the general Leibniz rule (5.1) for an arbitrary discrete derivative we obtain from (3.4), equating to zero the coefficients of $\Delta_x u, \Delta_t u, \Delta_x u$ and $u$, respectively, the following set of determining equations

$$D_x(\tau) = 0,$$

$$D_t(\tau) - 2D_x(\xi) = 0,$$

$$D_t(\xi) - D_{xx}(\xi) - 2D_x(f) = 0,$$

$$D_t(f) - D_{xx}(f) = 0.$$  \hspace{1cm} (5.3)

where $D_{xx}(f) = D_x(D_x(f))$.

For the cases $\Delta_x^\pm$ and $\Delta_x^s$ from (5.3) we recover the determining equations (3.6) and (4.7), respectively.

We have always four equations, whose general solution will depend on the formal expression of the corresponding $\Delta$. In fact, as long as we are able to find for the discrete derivative $\Delta$ the operator $\beta$ satisfying the commutator (4.2) this will allow us to give particular solutions to the determining equations (5.3) keeping the same Lie structure of the symmetries of the classical heat equation. Of course, some of these discrete symmetries can have a rather complicated expression with a nonlocal character, but this feature is a consequence of the structure of the operator $\beta$.

This procedure can be straightforwardly applied to other discretisations such as the wave equation [11] or even equations including a potential term.

Something similar happens with discrete equations on a q-lattice: once we have a solution for $\beta$ we can derive symmetry operators with a Lie structure (a situation which is seldom considered). On the other hand, if we are more interested in local symmetries, with some restrictions, the natural structure is that of a q–algebra. However, these issues are out of our present scope and they will be published elsewhere.
