HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
We study the quantum three-body free space problem of two same-spin-state fermions of mass \( m \) interacting with a different particle of mass \( M \), on an infinitely narrow Feshbach resonance with infinite \( s \)-wave scattering length. This problem is made interesting by the existence of a tunable parameter, the mass ratio \( \alpha = m/M \). By a combination of analytical and numerical techniques, we obtain a detailed picture of the spectrum of three-body bound states, within each sector of fixed total angular momentum \( l \). For \( \alpha \) increasing from 0, we find that the trimer states first appear at the \( l \)-dependent Efimovian threshold \( a^{(l)}_e \), where the Efimov exponent \( s \) vanishes, and that the entire trimer spectrum (starting from the ground trimer state) is geometric for \( \alpha \) tending to 0 from above, with a global energy scale that has a finite and non-zero limit. For further increasing values of \( \alpha \), the least bound trimer states still form a geometric spectrum, with an energy ratio \( \exp(2\pi/|s|) \) that becomes closer and closer to unity, but the most bound trimer states deviate more and more from that geometric spectrum and eventually form a hydrogenoid spectrum.

I. INTRODUCTION

The quantum few-body problem is the subject of a renewed interest [1], thanks to the possibility of experimentally studying this problem in a resonant regime with cold atoms close to a Feshbach resonance [2]. In this resonant regime, the \( s \)-wave scattering length \( a \) associated to the interaction among the particles can be made much larger in absolute value than the interaction range. This has in particular allowed to study the Efimov effect in the background of analytical and numerical techniques, we obtain a detailed picture of the spectrum of three-body bound states, within each sector of fixed total angular momentum \( l \). For \( \alpha \) increasing from 0, we find that the trimer states first appear at the \( l \)-dependent Efimovian threshold \( a^{(l)}_e \), where the Efimov exponent \( s \) vanishes, and that the entire trimer spectrum (starting from the ground trimer state) is geometric for \( \alpha \) tending to 0 from above, with a global energy scale that has a finite and non-zero limit. For further increasing values of \( \alpha \), the least bound trimer states still form a geometric spectrum, with an energy ratio \( \exp(2\pi/|s|) \) that becomes closer and closer to unity, but the most bound trimer states deviate more and more from that geometric spectrum and eventually form a hydrogenoid spectrum.

I. INTRODUCTION

The quantum few-body problem is the subject of a renewed interest [1], thanks to the possibility of experimentally studying this problem in a resonant regime with cold atoms close to a Feshbach resonance [2]. In this resonant regime, the \( s \)-wave scattering length \( a \) associated to the interaction among the particles can be made much larger in absolute value than the interaction range. This has in particular allowed to study the Efimov effect in the lab, up to now for three bosons and for three distinguishable particles [3], that is the emergence for \( 1/a = 0 \) of an infinite number of trimer states with an accumulation point at zero energy in the vicinity of which the spectrum forms a geometric sequence. Whereas the existence of an infinite number of bound states is common for long range interactions (vanishing for diverging interparticle distance \( r_{12} \) as \( 1/r_{12}^2 \) or more slowly), this is quite intriguing for short range interactions. Initially predicted by Efimov for three bosons, this effect can actually take place in more general situations [4], in particular in the so-called \( 2+1 \) fermionic problem if the extra particle is light enough [5].

What we call here the \( 2+1 \) fermionic problem consists in the system of two same spin state fermions of mass \( m \) interacting with a particle of mass \( M \) of another species. It is assumed that there is no direct interaction among the fermions, whereas there is a resonant interaction between each fermion and the extra particle, that is with an infinite \( s \)-wave scattering length, \( 1/a = 0 \). Furthermore, it is assumed that this resonant interaction is due to an infinitely narrow Feshbach resonance, that is of vanishing van der Waals range \( b \to 0 \) and finite effective range \( r_e \).

This concept is most easily understood in a two-channel model. In the open channel, the particles exist in the form of atoms, and have a weak, non-resonant direct van der Waals interaction corresponding to the background scattering length \( a_{bg} \approx b \) and the interaction range \( b \). In the closed channel, the particles exist in the form of a bound state of a fermion with the other-species-atom, the so-called closed-channel molecule with radius \( \approx b \). Due to a coupling \( \Lambda \) between the two channels, that we shall precisely define later, the closed-channel molecule is coherently converted into a pair of atoms in the open channel, and vice-versa. For an appropriate Zeeman tuning (with a magnetic field) of the bare energy \( E_{\text{mol}} \) of the closed-channel molecule with respect to the dissociation limit of the open channel, the \( s \)-wave scattering length \( a \) between a fermion and the other-species-atom is infinite. In this case, in simple models, the effective range \( r_e \) is the sum of two contributions [6]. The first one is, as expected, of the order of the van der Waals length \( b \). The second one is induced by the interchannel coupling; it is expressed as \(-2R_e [7]\), where the Feshbach length \( R_e \) is positive and scales as \( 1/\Lambda^2 \):

\[
R_e = \frac{\pi \hbar^4}{\Lambda^2 \mu}
\]

where \( \mu \) is the reduced mass of a fermion and the other-species particle. When the interchannel coupling \( \Lambda \) is very weak, this second contribution dominates over the first one, \( R_e \gg b \), and this is the narrow Feshbach resonance regime. An example under current theoretical and experimental investigation is the case of the interspecies Feshbach resonances of the fermionic \(^6\text{Li}\) and the fermionic \(^{40}\text{K}\), which are narrow: The Feshbach length \( R_e \) exceeds 100 nm, whereas the van der Waals length is a few nanometers [8–10].

To obtain the infinitely narrow Feshbach resonance model, here for \( 1/a = 0 \), one takes the mathematical limit of a vanishing van der Waals range \( b \) with a fixed non-zero interchannel coupling \( \Lambda \). The \( s \)-wave scattering amplitude between one fermion and the extra particle for
a relative wave vector $k$ is then $[7]$:

$$f_k = \frac{-1}{ik + k^2R_*}. \tag{2}$$

This implies the absence of two-body bound states, since $f_k$ can not have a pole for $k = iq$, $q > 0$. The model can however certainly support trimer states since the $2 + 1$ fermionic problem is subjected to the Efimov effect for a large enough mass ratio $m/M$ $[4, 5]$.

The main motivation of the present work is to study the spectrum of trimers for this problem in free space for $1/\alpha = 0$, in particular to determine analytically the global energy scale of the Efimovian part of the spectrum, related to the so-called three-body parameter. This global energy scale is out of reach of Efimov’s zero range theory $[4]$ but it was determined analytically for three bosons for a narrow Feshbach resonance in $[11, 12]$. Here we shall generalize this calculation to the present $2 + 1$ fermionic problem. A second motivation is to determine the low-lying states of each Efimov trimer series, which in this way may thus appear for lower mass ratios.

The paper is organized as follows. After a presentation of the model and the derivation of an integral equation à la Skorniakov-Ter-Martirosian $[13]$ for the three-body problem in momentum space in section II, analytical solutions of this integral equation are obtained in limiting cases in section III. In the central section IV of the paper, we analytically explore the physics of the trimers: Of particular interest are the exact results on the global energy scale in the Efimovian part of the spectrum, see subsection IV C. An efficient numerical solution of the integral equation is used in section V to explore intermediate regimes not covered by the analytics. We conclude in section VI.

## II. THE MODEL AND THE GENERAL MOMENTUM SPACE EQUATION

A tractable though realistic description of a Feshbach resonance is obtained with the so-called two-channel models, where the particles exist either in the form of atoms in the open channel or in the form of molecules in the closed channel $[2, 14–20]$. We use here the same free space two-channel model Hamiltonian $H$ as in $[21]$ written in momentum space in second quantized form in terms of the fermionic annihilation operators $c_k$, the extra-particle annihilation operators $b_k$ and the closed-channel molecule annihilation operators $a_k$:

$$H = H_{at} + H_{mol} + H_{at-mol} + H_{open}, \tag{3}$$

with

$$H_{at} = \int \frac{d^3k}{(2\pi)^3} \left[ E_{k} c_{k}^\dagger c_{k} + \alpha E_k a_{k}^\dagger a_{k} \right] \tag{4}$$

$$H_{mol} = \int \frac{d^3k}{(2\pi)^3} \left[ E_{mol} + \frac{\alpha}{1+\alpha} E_k \right] b_{k}^\dagger b_{k} \tag{5}$$

$$H_{at-mol} = \Lambda \int \frac{d^3k_1 d^3k_2 d^3k_3 d^3k_4}{[(2\pi)^3]^4} \chi(k_{12}) \left[ b_{k_1}^\dagger c_{k_1} c_{k_2} a_{k_3} a_{k_4} + h.c. \right] \tag{6}$$

$$H_{open} = g_0 \int \frac{d^3k_1 d^3k_2 d^3k_3 d^3k_4}{[(2\pi)^3]^4} \chi(k_{12}) \chi(k_{43}) \times (2\pi)^3 \delta(k_1 + k_2 - k_3 - k_4) a_{k_1}^\dagger c_{k_2}^\dagger c_{k_3} c_{k_4} \tag{7}$$

Whereas the $c_k$ obey the usual free space anticommutation relations

$$\{c_k, c_{k'}^\dagger \} = (2\pi)^3 \delta(k - k'), \tag{8}$$

the statistical nature (fermionic or bosonic) of the extra particle and of the closed-channel molecule does not need to be specified here, since there will be at most one of the particles in the state vector. Simply, the $c_k$ and $c_{k'}^\dagger$ commute with $a_k$ and $b_k$. In the kinetic energy terms of the atoms $H_{at}$ and of the closed-channel molecule $H_{mol}$, we have introduced the free fermion dispersion relation $E_k = \hbar^2 k^2 / (2m)$ and the mass ratio of a fermion to the extra particle:

$$\alpha \equiv \frac{m}{M}. \tag{9}$$

The internal energy $E_{mol}$ of the closed-channel molecule is counted with respect to the dissociation limit of the open channel and is experimentally adjusted thanks to the Zeeman effect by tuning of the external magnetic field. $H_{at-mol}$ represents the coherent interconversion of a closed-channel molecule into one fermionic atom and the extra particle, due to the coupling between the closed channel and the open channel. It involves the interchannel coupling constant $\Lambda$ and is regularized by the momentum space cut-off function $\chi$, assumed to be real and rotationally invariant, that tends to one a zero momentum, and that rapidly tends to zero at large momenta with a width $1/b$, where the interaction range $b$ is of the order of the van der Waals length. Note that the argument of the cut-off function $\chi$ is the relative wave vector of a fermion (of momentum $\hbar k_2$) with respect to the extra particle (of momentum $\hbar k_1$):

$$k_{12} \equiv \mu \left( \frac{k_2}{m} - \frac{k_1}{M} \right) = \frac{k_2 - \alpha k_1}{1 + \alpha}, \tag{10}$$

where

$$\mu = \frac{mM}{m + M} \tag{11}$$

is the reduced mass, so as to preserve Galilean invariance. Finally, $H_{open}$ models the direct interaction between atoms in the open channel, in the form of a separable potential with bare coupling constant $g_0$ and the same
cut-off function $\chi$ as in $H_{\text{at-mol}}$. This direct interaction is characterized by the so-called background scattering length $a_{bg}$. The inclusion of both $H_{\text{at-mol}}$ and $H_{\text{open}}$ allows to recover the usual expression for the scattering length as a function of the magnetic field $B$ [2],

$$a(B) = a_{bg} \left(1 - \frac{\Delta B}{B - B_0}\right)$$

if $E_{\text{mol}}$ is taken to be an affine function of $B$. The quantity $\Delta B$ is the so-called magnetic width of the Feshbach resonance.

We now derive from the model Hamiltonian a momentum space integral equation à la Skorniakov-Ter-Martirosian [13] for the three-body problem of two fermions and one extra particle, closely following reference [21] downgraded from the 3+1 to the 2+1 case. In the search for bound states, we take a negative eigenenergy, $E < 0$, and we express Schrödinger’s equation 0 = $(H - E)|\Psi\rangle$ for a set of zero total momentum and being the sum of general ansatz with zero or one closed-channel molecule: $|\Psi\rangle = |\psi_{3 \text{at}}\rangle + |\psi_{1 \text{at+1 mol}}\rangle$, with

$$|\psi_{3 \text{at}}\rangle = \frac{d^3k_1d^3k_2d^3k_3}{(2\pi)^3}
(2\pi)^3\delta(k_1 + k_2 + k_3)
\times A(k_1, k_2, k_3)\chi^+_{k_1}\chi^+_{k_2}\chi^+_{k_3}|0\rangle$$

$$|\psi_{1 \text{at+1 mol}}\rangle = \frac{d^3k}{(2\pi)^3} B(k)\delta^+_{k_1^-k_2^-k_3^-}|0\rangle.$$  

Thanks to the fermionic antisymmetry we can impose that $A(k_1, k_2, k_3)$ is an antisymmetric function of $k_2$ and $k_3$. On the contrary, a fermionic atom and a closed-channel molecule are distinguishable objects and there is no exchange symmetry constraint on the function $B(k)$. Projecting Schrödinger’s equation on the subspace with three atoms, and using $E < 0$, we are able to express $A$ in terms of $B$ and of an auxiliary unknown function $\tilde{B}$ obtained by a partial contraction of $A$:

$$\tilde{B}(k_3) = \int \frac{d^3k_1d^3k_2}{(2\pi)^3}
\chi(k_12)(2\pi)^3\delta(k_1 + k_2 + k_3)
\times A(k_1, k_2, k_3).$$

More precisely,

$$A(k_1, k_2, k_3) = \frac{\Lambda/2}{E - (\alpha E_{k_1} + E_{k_2} + E_{k_3})}
\times [\chi(k_12)D(k_3) - \chi(k_13)D(k_2)]$$

where the convenient unknown function is actually $D$ such that

$$\Lambda D(k) = \Lambda B(k) + 2\hbar\tilde{B}(k).$$

Plugging the expression (16) of $A$ into the definition (15) of $\tilde{B}$ gives a first important equation

$$\frac{2\Lambda}{\Lambda} \tilde{B}(k_3) = \int \frac{d^3k_1d^3k_2}{(2\pi)^3}
\chi(k_12)(2\pi)^3\delta(k_1 + k_2 + k_3)
\times \left[\chi(k_12)D(k_3) - \chi(k_13)D(k_2)\right].$$

The second important equation is obtained by projecting Schrödinger’s equation on the subspace with one atom and one closed-channel molecule (in which case the direct open-channel interaction can not contribute):

$$2\Lambda\tilde{B}(k) = |E_{\text{rel}}(k) - E_{\text{mol}}|B(k)$$

where we have introduced what we call the relative energy

$$E_{\text{rel}}(k) = E - \left(E_k + \frac{\alpha}{1 + \alpha}E_k\right).$$

This is indeed the relative energy of one of the fermions and of the extra particle, knowing that the second fermion has a wave vector $k$, since one subtracts in (20) from the total energy $E$ the kinetic energy $E_k$ of the second fermion and the center of mass kinetic energy of the first-fermion-plus-extra-particle. One expresses $B$ in terms of $D$ by elimination of $B$ between (17) and (19). One then eliminates $\tilde{B}$ between the resulting equation and (18) to finally obtain a closed equation for $D$:

$$0 = \frac{\mu D(k_3)}{2\hbar^2f|E_{\text{rel}}(k_3)|} - \int \frac{d^3k_1d^3k_2}{(2\pi)^3}
(2\pi)^3\delta(k_1 + k_2 + k_3)
\times \left[\chi(k_12)\chi(k_13)D(k_2)\right]
\times \chi(k_12)\chi(k_13)D(k_2),$$

The function $f$ is related to the two-body $T$ matrix for the scattering of a fermion and of the extra particle [21],

$$(k_f|T(\epsilon + i0^+)|k_i) = -\frac{2\hbar^2}{\mu}\chi(k_f)\chi(k_i)f(\epsilon + i0^+)$$

where the relative wave vectors $k_i, k_f$ and the energy $\epsilon$ are arbitrary (the $T$ matrix is not necessarily on shell that expression).

The general expression of $f$ is given in [21]. Here however, we shall concentrate on the limit of an infinitely narrow Feshbach resonance. We thus take the zero-range limit $b \to 0$, in which case the cut-off function $\chi$ (of width $\propto 1/b$) tends to unity. It is assumed that there is no resonant interaction in the open channel, so that the corresponding background scattering length $a_{bg}$ is $O(b)$ and also tends to zero. On the contrary, the interchannel coupling $\Lambda$ is kept fixed, so as to keep a non-zero effective range, and $E_{\text{mol}}$ is adjusted to keep a fixed value of the scattering length $a$. In this case, the function $f$ for a positive and fixed energy $\epsilon > 0$ (so that $\mu b^2/\hbar^2 \to 0$) simply tends to the $s$-wave scattering amplitude $f_k$ on an infinitely narrow Feshbach resonance [7]:

$$f(\epsilon + i0^+) = f_k$$

with

$$f_k = \frac{1}{a^{-1} + ik + k^2R_*}.$$
The Feshbach length $R_\ast$ is expressed in terms of the width $\Delta B$ of the Feshbach resonance as [7]:

$$R_\ast = \frac{\hbar^2}{2\mu_0a_0\Delta B},$$

(25)

where the differential magnetic moment between the closed and open channels is $dE_{\text{coll}}/dB$ taken for $B = B_0$. In (24), the relative wavenumber $k = (2\mu_0)^{1/2}/\hbar$ since the energy is positive. For a negative energy, the function $f$ has the same expression (23) if one uses the analytic continuation $k = i(-2\mu_0)^{1/2}/\hbar$ in $f_k$ [22].

It is convenient to represent the eigenenergy $E$ in terms of a wavenumber, setting

$$E = -\frac{\hbar^2q^2}{2\mu},$$

(26)

where we recall that $\mu = mM/(m + M)$ is the reduced mass and $q \geq 0$. Similarly the relative energy is represented by a wavenumber, $E_{\text{rel}}(k) = -\hbar^2q_{\text{rel}}(k)/(2\mu)$ leading to

$$q_{\text{rel}}(k) = \left[ q^2 + \frac{1 + 2\alpha}{1 + \alpha^2} k^2 \right]^{1/2}. $$

(27)

For an infinitely narrow s-wave Feshbach resonance with a scattering length $a$, the integral equation resulting from Schrödinger’s equation, the equivalent of the Skorniakov-Ter-Martirosian equation [13] for our problem, is then

$$0 = [-a^{-1} + q_{\text{rel}}(k) + q_{\text{rel}}^2(k)R_\ast] \, D(k) + \int \frac{d^3k'}{2\pi^2} \frac{D(k')}{q^2 + k^2 + k'^2 + \frac{2\alpha}{1+\alpha} k \cdot k'}. $$

(28)

In that equation, for the sake of generality, we have kept an arbitrary value of the scattering length $a$. In what follows, we shall restrict to the exact resonance location where $1/a = 0$.

We shall also take advantage of rotational invariance to reduce the integral equation to an unknown function of a single variable only, as done in [13]. The eigenstates of the Hamiltonian $H$ may be assumed of a fixed total angular momentum of angular quantum number $l$. Without loss of generality one can also assume that the angular momentum along the quantization axis $z$ is zero. The corresponding ansatz for $D$ is thus

$$D(k) = Y_{l}^{0}(k)f^{(l)}(k)$$

(29)

where the notation $Y_{l}^{m}(k)$ stands for the spherical harmonics $Y_{l}^{m}(\theta, \phi)$ where $\theta$ and $\phi$ are respectively the polar and azimuthal angles of the vector $k$ in a system of spherical coordinates of polar axis $z$. The unknown function $f^{(l)}$ then depends only on the modulus $k$ of $k$. We see that this also fixes the parity of the eigenstate to the value $(-1)^l$. In the integral over $k'$ in (28), we then perform the change of variable of unit Jacobian,

$$k' = R K$$

(30)

where $R$ is the rotation in $\mathbb{R}^3$ defined by the Euler decomposition of its inverse:

$$R^{-1} = R_{z}(-\phi)R_{\theta}(\theta)R_{z}(\pi - \phi)$$

(31)

where the notation $R_{i}(\alpha)$ stands for the rotation of an angle $\alpha$ around the axis $i \in \{x, y, z\}$. This choice ensures that $k/k = R e_z$, where $e_z$ is the unit vector defining the $z$ axis. In the denominator of the integrand of (28), the scalar product $k \cdot k'$ is then transformed as $k e_z \cdot K$, so that the denominator is invariant by rotation of $K$ around $z$.

In the numerator we use the transformation of spherical harmonics under rotation, see (8.6-2) and (8.6-1) in [23], and the relation $[Y_{l}^{m}(\theta, -\phi)]^{*} = Y_{l}^{m*}(\theta, \phi)$:

$$Y_{l}^{0}(KR) = \left( \frac{4\pi}{2l + 1} \right)^{1/2} \sum_{m_l = -l}^{l} Y_{l}^{m}(K) Y_{l}^{m}(K),$$

(32)

which in particular allows to pull out the factors $Y_{l}^{m}(K)$ expected from rotational invariance. The integration over $K$ is then conveniently performed in spherical coordinates of polar axis $z$. All the terms with $m_l \neq 0$ in (32) vanish in the integration over the azimuthal angle of $K$. From the expression of the spherical harmonics in terms of the Legendre polynomial of degree $l$ [23],

$$Y_{l}^{0}(K) = \left( \frac{4\pi}{2l + 1} \right)^{-1/2} P_{l}(u = K \cdot e_z/K),$$

(33)

we finally obtain the reduced integral equation to be solved in the sector of angular momentum $l$, for $1/a = 0$:

$$0 = [q_{\text{rel}}(k) + q_{\text{rel}}^2(k)R_\ast] \, f^{(l)}(k) + \int_{0}^{+\infty} \frac{dK}{\pi} f^{(l)}(K) \int_{-1}^{1} du \frac{P_{l}(u)K^2}{q^2 + k^2 + K^2 + \frac{2\alpha}{1+\alpha} k \cdot K u}.$$

(34)

### III. ANALYTICAL SOLUTIONS IN PARTICULAR CASES

Several remarkable analytical techniques are now available to solve the three-body problem in some appropriate limiting cases [5, 11, 12, 24, 25]. Whereas we do not know how to solve (34) analytically in general, it is possible to find solutions when there is an extra symmetry available, that is scale invariance. The most standard regime corresponds to the limit $R_\ast \to 0$, in which case our model reduces to the so-called zero-range or Bethe-Peierls model, where the interactions are included via two-body contact conditions on the wavefunction [26]. Since $1/a = 0$, these contact conditions are indeed scaling invariant, which allows to fully solve the problem [4, 27]. Because the zero-range model is usually solved in position space, it is interesting here to briefly show the calculations in momentum space. In the regime of interest, where the Efimov effect takes place, the zero-range model is however not
well defined, and an extra three-body condition has to be introduced to make it self-adjoint [28], involving the three-body parameter. 

So the relevant case here is $R_s > 0$. The existence of such a finite length scale characterizing the interactions breaks the scale invariance. Fortunately, as shown in [12], if one restricts to the zero energy case $E = 0$, equations of the type (34) can still be solved analytically. This gives access to the three-body parameter, and thus to the characterization of the Efimov spectrum of trimers.

A. Zero-range case ($R_s = 0$) at zero energy

For $R_s = 0$ and at zero energy $q = 0$, the integral equation (34) is manifestly scaling invariant: If $f^{(1)}(k)$ is a solution, the function $f^{(1)}_f(k) = f^{(1)}(k/\lambda)$ is also a solution, $\forall \lambda > 0$, and we expect that the two functions $f^{(1)}$ and $f^{(1)}_f$ are proportional. We thus seek a solution in the form of a power-law,

$$ f^{(1)}(k) = k^{-(s+2)}. \quad (35) $$

The form of the exponent results from the general theory, see section 3.5 in [29]: For a $N$-body problem, with here $N = 3$, for $s$ to be a direct generalization of the exponent $s_0$ introduced by Efimov [4], the exponent in (35) should be $-s(3N-5)/2$. For convergence issues, it is simpler to assume in explicit calculations that $s = iS$, where $S$ is real. By analytic continuation, the result however extends to real $s$ also, as also shown by the real space calculation [30]. We inject the ansatz (35) in (34) with $s = 0$, $R_s = 0$, and we perform the change of variable $K = ke^x$ to obtain an equation for $s$:

$$ 0 = \Lambda_t(s), \quad (36) $$

with the function

$$ \Lambda_t(s) = \frac{(1 + 2\alpha)^{1/2}}{1 + \alpha} + \int_{-1}^{1} du P_1(u) \int_{-\infty}^{+\infty} dx \frac{e^{-iSx}}{2\pi \cosh x + \frac{\alpha}{1+\alpha} u}. \quad (37) $$

Using contour integration and the Cauchy residue formula, the integral over $x$ may be calculated: Setting

$$ \theta = \arccos \left( \frac{\alpha}{1+\alpha} u \right), \quad \text{so that } \theta \in [0, \pi], \quad \text{we obtain} $$

$$ \int_{-\infty}^{+\infty} dx \frac{e^{-iSx}}{2\pi \cosh x + \frac{\alpha}{1+\alpha} u} = \frac{\sin(s\theta)}{\sin(s\pi) \sin \theta}. \quad (38) $$

Successive integration over $u$ is simplified by taking $\theta$ rather than $u$ as integration variable, with a Jacobian that simplifies with the factor $\sin \theta$ in the denominator of (38). Following [5] we then parameterize the mass ratio by an angle $\nu \in [0, \pi/2]$:

$$ \nu = \arcsin \frac{\alpha}{1 + \alpha} = \arcsin \frac{m}{M}. \quad (39) $$

which leads to the remarkable property

$$ \cos \nu = \frac{(1 + 2\alpha)^{1/2}}{1 + \alpha}. \quad (40) $$

Also using $\arccos[\alpha/(1 + \alpha)] = \frac{\pi}{2} - \nu$, we obtain

$$ \Lambda_t(s) = \cos \nu + \int_{-\nu}^{\nu} d\nu P_1 \left( \frac{\cos \theta}{\sin \nu} \frac{\sin(s\theta)}{\sin(s\pi)} \right). \quad (41) $$

This can be further simplified taking advantage of the parity of the Legendre polynomial, $P_1(-u) = (-1)^l P_1(u)$ for all $u$, by shifting the integration variable $\theta$ by $\pi/2$. Depending on the even or odd parity of the angular momentum $l$ this reduces to

$$ \Lambda_t(s)^{l\text{even}} = \cos \nu + \int_{-\nu}^{\nu} d\nu P_1 \left( \frac{\sin \theta}{\sin \nu} \cos(s\nu) \right), \quad (42) $$

$$ \Lambda_t(s)^{l\text{odd}} = \cos \nu - \int_{-\nu}^{\nu} d\nu P_1 \left( \frac{\sin \theta}{\sin \nu} \sin(s\nu) \right). \quad (43) $$

Eq. (43) will be quite useful to obtain analytical results on the Efimovian trimer spectrum in the large $\alpha$ limit, see subsections IV A and IV B.

An explicit expression of $\Lambda_t(s)$ as a sum of a finite number of simple functions of $s$ may be obtained by representing the function $P_1(\sin \theta)$ as a Fourier sum, that is a sum of $\cos n\theta$, $0 \leq n \leq 1$, $n$ even, for an even $l$, and a sum of $\sin n\theta$, $1 \leq n \leq l$, $n$ odd, for an odd $l$. The coefficients are polynomials of $1/\sin \nu$ that are simple to calculate analytically from the known coefficients of the Legendre polynomials $P_1(u)$ [31]. The resulting integrals over $\theta$, e.g. of $\sin(n\theta) \sin(n\theta)$, are then straightforward to evaluate. We finally obtain the explicit formula valid for arbitrary parity of $l$:

$$ \Lambda_t(s) = \cos \nu + \frac{1}{\sin \nu \cos((s + l)\pi/2)} \times \sum_{n=0}^{l} c_n \left\{ \frac{\sin(s + n\nu)}{s + n} + (-1)^n \frac{\sin(s - n\nu)}{s - n} \right\}. \quad (44) $$

The coefficients $c_n$ are zero for $l-n$ odd. For $l-n$ even,

$$ c_n = \left( 1 - \frac{1}{2} \delta_{n,0} \right) \left( \frac{(-1)^{l+n}/2}{(4\sin \nu)^j} \times \sum_{k=0}^{(l-n)/2} \frac{(-4 \sin^2 \nu)^k (2l - 2k)!}{k!(l - k)! (\frac{1-n}{2} - k)! (\frac{1+n}{2} - k)!} \right). \quad (45) $$

where $\delta_{ij}$ is the usual Kronecker delta.

The form (44) has the interesting feature that the coefficients are $s$-independent, which makes the numerical evaluation of $\Lambda_t(s)$ as a function of $s$ particularly efficient. As a test, it is however interesting to compare to the transcendental equation for $s$ obtained by the direct calculation à la Efimov in position space. As detailed in the Appendix A, introducing the hypergeometric function $F_1$ as in [32] to solve some differential equation, we
generalize the formulas of [32] to an arbitrary mass ratio, a
generalization that was done already with the adiabatic
hyperspherical method in [33]:

\[
A_l(s) = \cos \nu + (-1)^l \sin \nu \Gamma \left(\frac{l+1+s}{2}\right) \Gamma \left(\frac{l+1-s}{2}\right)
\]
\[\times 2F_1 \left(\frac{l+1+s}{2}, \frac{l+1-s}{2}, l+\frac{3}{2}; \sin^2 \nu\right)\]  
(46)

where \( \Gamma \) is the Gamma function. A variant of Eq. (46) will
be quite useful to obtain analytical results on the
Elinovian trimer spectrum in the large \( l \) limit, see sub-
sections IV A and IV B.

B. Zero range case \((R_e = 0)\) at negative energy

Once the imaginary values of the Elinov exponent \( s \) are
determined by solution of the transcendent equa-
tion \( \Lambda_l(s) = 0 \), which is possible for \( l \) odd and \( \alpha \) larger
than a critical value \( \alpha_c \); see subsection IV A, one can
determine the corresponding Elinovian trimer solutions of
the zero-range theory at arbitrary energies, in free space
and also in an isotropic harmonic trap, using the general
real space formalism relying on separability of the
Bethe-Peierls problem in hyperspherical coordinates [27, 29, 30].
Here we find it interesting to deduce from the real space
solution the explicit form of the momentum space solu-
tion, restricting for simplicity to the values of the mass
ratio \( m \) and the (necessarily odd) angular momentum \( l \)
such that the Elinov effect takes place. This may be
useful for example to calculate the atomic momentum
distribution of the Elinov trimer states in the zero-range
limit, as was done for three bosons in [34].

The idea to obtain \( D(k) \) is to take the limit of the
position \( r_1 \) of the extra particle and the position \( r_2 \)
of a fermionic atom converging to the same location, with
a fixed value of their center of mass position and of
the position \( r_3 \) of the second fermionic atom. According
to the Bethe-Peierls framework, the atomic wave-
function \( \psi(r_1, r_2, r_3) \) shall then diverge as \( 1/r \), with
\( r = r_1 - r_2 \), with a factor depending on the Jacobi
coordinate \( x = r_3 - (r_1 + m r_2)/(M + m) \):

\[
\psi(r_1, r_2, r_3) \overset{\text{fixed}}{\sim} \frac{A(x)}{r}.
\]  
(47)

Then one calculates \( A(x) \) in two different ways. First,
one uses Elinov solution exposed in the Appendix A:
From Elinov’s ansatz (A1) and from the solution \( F(R) \propto
K_\nu[(\bar{m}/\mu)^{1/2} q R] \) of the hyperradial equation (A6),
where \( \bar{m} \) is an arbitrary mass unit and \( K_\nu \) a Bessel function,
one finds for a vanishing angular momentum along \( z \):

\[
A(x) \propto Y_\nu^0(x) \frac{K_\nu(Q x)}{x},
\]  
(48)

where we have set

\[
Q \equiv q \left( \frac{\mu_{am}}{\mu} \right)^{1/2} = \frac{1 + \alpha}{(1 + 2\alpha)^{1/2}} q = \frac{q}{\cos \nu}
\]  
(49)

where \( \mu_{am} \) is the reduced mass of one fermionic atom
of mass \( m \) and one pair of fermion-plus-extra-particle of
mass \( m + M \). Second, after inspection of (13), one cal-
culates the atomic wavefunction \( \psi \) by taking the Fourier
transform of \( A(k_1, k_2, k_3) = 2\pi^{d/2} \delta(k_1 + k_2 + k_3) \),
where \( A \) is given by of (16), taking the functions \( \chi \) equal to unity.
As expected, the contribution involving \( \chi(k_{12}) D(k_3) \) is
the one leading to a divergence of \( \psi \) for \( r \to 0 \). Inte-
gration over \( k_1 \) is straightforward thanks to the factor
\( (2\pi)^d \delta(k_1 + k_2 + k_3) \). Then integration over \( k_2 \) can be
done after the change of variable \( k_2 = k_3 - \frac{i}{\cos \nu} k_3 \), using

\[
\int d^3 k_3 e^{-i k_3 x} \frac{1}{(2\pi)^d} D(k_3) e^{i k_3 x}.
\]  
(51)

We thus set, for an arbitrary choice of normalization lead-
ing to a dimensionless function:

\[
D(k) = \int d^3 x e^{-ik \cdot x} \int \frac{Q^2 K_\nu(Q x)}{x}.
\]  
(52)

A first technique to calculate the integral in (52) is to
use the expansion of the plane wave on spherical
harmonics: According to the identity (8.7-13) in [23], the
amplitude of the function \( x \to e^{ik \cdot x} \) on the spherical
harmonics \( Y_{lm}^m(x) \) is \( 4\pi^{d/2} j_l(k x) Y_{lm}^m(k \cdot x) \), where the
spherical Bessel function is real and may be expressed in terms
of the usual Bessel function \( J \):

\[
\int \frac{Q^2 K_\nu(Q x)}{x} = \int \frac{1}{2\pi} (\frac{\pi}{2 k})^{1/2} J_{l+1/2}(kr).
\]  
(53)

It turns out that the integral over \( \mathbb{R}^+ \) of the product of a
power law and of two Bessel functions may be expressed
exactly in terms of the hypergeometric function \( _2F_1 \), see
relation 6.576(3) in [31]:

\[
D(k) = 2\pi^{3/2} (i)^l (k/Q)^l Y_{lm}^0(k) \frac{\Gamma(1 + l + s)}{\Gamma(l + 3/2)}
\]
\[\times 2F_1 \left(1 + \frac{l + s}{2}, 1 + \frac{l - s}{2}, l + \frac{3}{2}; -k^2/Q^2\right). \]  
(54)

This immediately shows that \( D(k) \) vanishes as \( k^l \) for \( k \to 0 \),
which is generically the case for a regular function of
angular momentum \( l \). It also allows to obtain the large
momentum behavior of \( D(k) \) [35],

\[
D(k) \propto k^{l+1/2} \frac{i/(2\pi)}{k^{3/2} \cos(s r s/2)} Y_{lm}^0(k)
\]
\[\times \left\{ \left(\frac{2k}{Q}\right)^l \prod_{n=0}^{(l-1)/2} \frac{s - (2n + 1)}{s + 2n} \right\}
\times \left[ 1 + \frac{l + s - 1(l - s + 2)}{4(1 - s)(k/Q)^2} + O(Q/k)^4 \right] + c.c \}
\]  
(55)
with contour integration: the need of hypergeometric functions. For \( k^2 D(k) \) to approach this asymptotic oscillating function, the very stringent condition \( k/Q \gg \exp(2\pi|s|) \) is fortunately not required, it is simply sufficient that \( k/Q \gg 1 \) (for \( l \) and \( |s| \) not much larger than unity).

A second technique to calculate (52) is to use spherical coordinates of axis the quantization axis \( z \). The integral over the azimuthal angle \( \phi \) is straightforward. The in- tegral over the polar angle \( t \), one replaces \( Y^0_l(x) \) by its expression in terms of the Legendre polynomial \( P_l(u) \) with the variable \( u = \cos \theta \), and one integrates by parts the factor \( 1/(\cosh t + ik u/Q)^2 \) that appeared after integration over \( x \). The integral over \( t \) can then be performed with contour integration:

\[
\int_{-\infty}^{+\infty} dt \frac{e^{-ist}}{2\pi \cosh t + i \sinh \beta} = \frac{\sin[\beta(\beta + i\pi/2)]}{\sinh(\beta \pi) \cosh \beta} \tag{56}
\]

where \( s \) and \( \beta \) are real quantities. Changing to the variable \( \beta = \text{argsh}(ku/Q) \) in the integral over \( u \), one obtains

\[
D(k) = \frac{Y^0_l(k)}{k \cosh(\pi/2)} \left\{ \frac{\cos[\text{argsh}(k/Q)]}{(k^2 + Q^2)^{1/2}} \right\}
- \frac{1}{k} \int_0^{\text{argsh}(k/Q)} d\beta P_l' \left( \frac{Q \sinh \beta}{k} \right) \cos(\beta) \tag{57}
\]

where we have set \( s = i\beta \). Generalizing the technique of subsection III A to the derivative \( P_l' \) of the Legendre polynomial allows a direct evaluation of \( D(k) \) without the need of hypergeometric functions.

C. Case \( R_\ast > 0 \) at zero energy

In this subsection, as in the previous one, we restrict to the case where an Efimov effect takes place: Anticipating on results of subsection IV A, the angular momentum quantum number \( l \) is odd and the mass ratio \( \alpha \) is larger than the corresponding critical value \( \alpha^{(0)}_c \), so that the function \( \Lambda_l(s) \) has a single purely imaginary root \( s_l = iS_l \) with positive imaginary part:

\[
\Lambda_l(iS_l) = 0 \quad \text{with} \quad S_l > 0. \tag{58}
\]

As remarkably shown for three bosons in [12] the narrow Feshbach resonance model can be solved analytically at zero energy, which gives access to the three-body parameter, that is to the energy scale in the asymptotically geometric Efimovian trimer spectrum.

The underlying idea of the solution is that, at zero energy and after division of the overall Eq. (34) by a factor \( k \), the integral part of the resulting equation is strictly scaling invariant. If one takes as variable the logarithm of \( k \) rather than \( k \), this strict scaling invariance corresponds to a translation invariance, which suggests that the integral part is simply a convolution product and leads one to perform a Fourier transform with respect to \( ln k \). More precisely, we use the ansatz:

\[
f^{(l)}(k) = e^{-x^2} F^{(l)}(x) \quad \text{with} \quad x = \ln(kR_\ast \cos \nu), \tag{59}
\]

where the factor \( e^{-x^2} \) shall lead to a convolution kernel with the desired even function, and \( \cos \nu \) is a function of the mass ratio given by Eq. (40). Dividing Eq. (34) for \( E = 0 \) by \( k \), injecting the ansatz (59) in the resulting equation, and finally multiplying by \( e^{x^2} \), we obtain

\[
0 = (1 + e^x) F^{(l)}(x) \cos \nu + \int_{-\infty}^{+\infty} dX K_l(X - x)F^{(l)}(X) \tag{60}
\]

with the kernel

\[
K_l(x) = \frac{1}{2\pi} \int_{-1}^{1} \frac{d\nu}{\cosh(x) + \frac{\alpha}{1 + \alpha \nu}}. \tag{61}
\]

As expected, (60) is the convolution product. We thus introduce the Fourier representation of the function \( F^{(l)} \) [36]:

\[
F^{(l)}(x) = \int_{-\infty}^{+\infty} e^{iSx} \tilde{F}^{(l)}(S) \tag{62}
\]

We expect that the function \( F^{(l)}(x) \) oscillates periodically for \( x \rightarrow -\infty \): When \( x \rightarrow -\infty \), the momentum \( k \) tends to 0, it becomes much smaller than \( 1/R_\ast \); one enters a universal zero-energy, zero-range regime where solutions of the type (35) are obtained, with \( s \) purely imaginary for an Efimovian solution. According to (59), this implies that \( F^{(l)}(x) \) has plane wave oscillations at \( x \rightarrow -\infty \), with a wavenumber \( \pm S_l \) since both \( s = iS_l \) and \( s = -iS_l \) are roots of \( \Lambda_l(s) = 0 \). More precisely, we expect that there exist coefficients \( A_l \) such that

\[
F^{(l)}(x) \xrightarrow{x \rightarrow -\infty} A_l e^{iS_l x} + A_{-l} e^{-iS_l x} + o(1). \tag{63}
\]

This will be checked a posteriori. As a consequence, the Fourier transform \( \tilde{F}^{(l)}(S) \) has singularities on the real axis. More precisely, Eq. (63) leads to the natural conclusion that

\[
\tilde{F}^{(l)}(S) \text{ has simple poles in } S = \pm S_l. \tag{64}
\]

This is why the integration contour in (62) is infinitesimally shifted upwards in the complex plane. This is a standard procedure in physics, see for example the expression of the unitary evolution operator as a Fourier transform of the resolvent for a system with time-independent Hamiltonian [37]. In this Fourier representation, the convolution becomes a product, and one needs to calculate the Fourier transform \( \tilde{K}_l(S) \) of the kernel
function $K$. Exchanging the integration over $u$ and $x$, one then recovers exactly the integral in Eq. (37) knowing that $s = iS$ in that equation, so that

$$\tilde{K}_l(S) = \Lambda(iS) - \cos \nu. \quad (65)$$

The only subtle part is the determination of the Fourier representation of the function $x \to e^{xF^{(l)}(x)}$. Multiplying (62) by $e^x$ gives

$$e^x F^{(l)}(x) = \int_{-\infty}^{+\infty+0^-} \frac{dS}{2\pi} e^{i(S-i)x} \tilde{F}^{(l)}(S). \quad (66)$$

This is not directly of the Fourier form (62) because $S - i$ rather than $S$ appears inside the exponential. Now, if the integrand, that is here in practice the function $S \to \tilde{F}^{(l)}(S)$, is a meromorphic function with no singularities (no poles) in the band $0^+ \leq \text{Im} z \leq 1 + 0^+$, that is $0 < \text{Im} z \leq 1$, where $z \in \mathbb{C}$, we can shift the integration contour in (66) upwards by one unity along the vertical axis in the complex plane, so as to replace $S - i$ with $S$.

Under the hypothesis

$$\tilde{F}^{(l)}(z) \text{ has no singularities for } 0 < \text{Im} z \leq 1, \quad (67)$$

we thus have

$$e^x F^{(l)}(x) = \int_{-\infty}^{+\infty+0^-} \frac{dS}{2\pi} e^{iSx} \tilde{F}^{(l)}(S + i), \quad (68)$$

which is exactly of the Fourier functional form (62), that is the function $S \to \tilde{F}^{(l)}(S + i)$ is the Fourier transform of the function $x \to e^{xF^{(l)}(x)}$. This procedure is summarized on Fig.1, where the original (66) and the shifted (68) integration contours are plotted, and where the locations of the poles of $\tilde{F}^{(l)}(z)$ are also indicated. Eq. (60) then reduces to

$$0 = \tilde{F}^{(l)}(S + i) \cos \nu + \Lambda_l(iS) \tilde{F}^{(l)}(S) \quad (69)$$

for all real $S$.

To solve (69) we follow [12]. We first introduce the ansatz

$$\tilde{F}^{(l)}(S) = \frac{\pi}{\sinh[\pi(S + S_l)]} C_l(S) \quad (70)$$

where we recall that $iS_l$ is the positive-imaginary-part root of $\Lambda_l(s)$. The factor with the hyperbolic sine is carefully chosen so as to give a minus sign under translation $S \to S + i$, a priori introducing poles in $z = -S_l$, $z = -S_l + i$, $z = -S_l + 2i$, etc., for the function $\tilde{F}^{(l)}(z)$. This does not introduce singularities in the band $0 < \text{Im} z \leq 1$ provided that the function $C_l(z)$ tends to zero for $z \to -S_l + i$, a point to be checked a posteriori.

The unknown function $C_l$ solves

$$C_l(S + i) \cos \nu = \Lambda_l(iS) C_l(S) \quad (71)$$

on the real axis. According to the expectation (64), the function $C_l(S)$ has no pole in $S = -S_l$, since the $1/\sinh$ factor in (70) already has a simple pole in $S = -S_l$, and $C_l(S)$ has a simple pole in $S = S_l$, since the $1/\sinh$ factor has no pole there [38]. As in [12] one then uses the Weierstrass representation

$$\Lambda_l(iS) = \cos \nu \prod_{n=1}^\infty \frac{S^2 - u_n^2}{S^2 - v_n^2} \quad (72)$$

where the overall factor $\cos \nu$ is the limit of $\Lambda_l(iS)$ for $S \to \infty$, see Eq. (44). In Eq. (72), $u_0 = S_l$ is the real positive root of the function $S \to \Lambda_l(iS)$, $-u_0$ is the real negative root, and the $\pm u_n$, $n \geq 1$, are the purely imaginary roots of $S \to \Lambda_l(iS)$, $\text{Im} u_n > 0$. The $u_n$'s are sorted by ascending order of their imaginary parts, and for general values of the mass ratio $\alpha$, they form an irregular, aperiodic sequence. They of course depend on the angular momentum $l$. On the contrary, for general values of the mass ratio $\alpha$, the poles of $S \to \Lambda_l(iS)$ are found from (43) to simply be $\pm v_n$, with $v_n = i(2n + l + 1)$ for all integers $n \geq 0$ [39]. Finally, one can check as in [12] that the function $C_l$ is given by the infinite product

$$C_l(S) = \frac{\Gamma(iS_l - iS)\Gamma(1 + iS - iv_n)}{\Gamma(1 + iS + iv_n)\Gamma(-iS - iv_n)} \times \prod_{n \in \mathbb{N}^+} \frac{\Gamma(-iS - iv_n)\Gamma(1 + iS - iv_n)}{\Gamma(-iS - iv_n)\Gamma(1 + iS - iv_n)}. \quad (73)$$

FIG. 1: (color online) In the complex plane, illustration of the procedure used to determine the Fourier transform of the function $x \to e^{xF^{(l)}(x)}$: Under the a posteriori checkable hypothesis (67) (no pole of $\tilde{F}^{(l)}(z)$ in the grey area), one can shift the integration contour in (66) upwards by one unity along the vertical axis, to obtain the Fourier representation Eq. (68) of $x \to e^{xF^{(l)}(x)}$. Circles: Poles of $\tilde{F}^{(l)}(z)$ due to the function hyperbolic sine in the denominator of (70). Pluses: Poles of $\tilde{F}^{(l)}(z)$ due to the factors $\Gamma(1 + iz - iv_n)$, $n \geq 0$, in the numerators of the infinite product (73). Black crosses: Poles of $\tilde{F}^{(l)}(z)$ due to the factor $\Gamma(iS_l - iz)$ in (73). Colored crosses on the Im $z < 0$ part of the imaginary axis: Poles of $\tilde{F}^{(l)}(z)$ due to the factors $\Gamma(-iv_n - iz)$ for $n > 0$ in (73) [red: $n = 1$; blue: $n = 2$; violet: $n = 3$; cyan: $n = 4$]; from top to bottom, $n = 1$ (three crosses), $n = 2$ (two crosses), two triplets $n = 1, 2, 3$ and a quadruplet $n = 1, 2, 3, 4$. The figure corresponds to $l = 1$ and $\alpha = 20$. 
where we recall that the \(u_n\) and \(v_n\) depend on \(l\). In particular, one can check that this expression vanishes for \(S \to -S_l + i\), as required above Eq. (71), and has no pole in the band \(0 < \text{Im} z \leq 1\) of the complex plane [40]. Together with (70), this constitutes the desired solution at zero energy for \(R_s > 0\).

An important application of this result is to calculate the previously mentioned low-\(k\) or \(x \to -\infty\) behavior (63) of the solution [42], which is a universal regime that has to match the zero-range model. Since \(x < 0\), in applying the usual contour integration technique to (62), we close the integration contour following a half-circle in the lower part \(\text{Im} z < 0\) of the complex plane. According to the Cauchy residue formula, one gets for \(F^{(l)}(x)\) a sum of terms proportional to \(e^{izx}\), where the sum is taken over all poles \(z_n\) of the integrand in the lower half plane (see the pole locations in Fig.1). For \(x \to -\infty\), the poles with a non-zero imaginary part have a contribution that gives purely oscillating, non-decaying contributions. The corresponding residues of \(F^{(l)}(S)\) can be deduced from

\[
F^{(l)}(S) \sim \frac{C_l(-S_l)}{S + S_l} \quad \text{and} \quad F^{(l)}(S) \sim \frac{[C_l(-S_l)]^*}{S - S_l} - i \frac{C_l(-S_l)}{S + S_l}
\]

(74)
The value of the first residue directly results from the ansatz (70) and the absence of pole of the function \(C_l(S)\) in \(S = -S_l\). If one further uses (71) for \(S \to S_l\), one finds for the second residue \([\pi/\sinh(2\pi S_l)]C_l(S_l + i)\cos \nu/i \Lambda_l'(i S_l)\). Properties of the explicit form (73) and of the Gamma function, as in [12], lead to (74) [43]. Finally, turning back to the \(k\) variable and to the function \(D\):

\[
D(k) = \frac{-i}{Q} \left( \frac{q}{R_s} \right)^2 Y^0(k) \times \left\{ [C_l(-S_l)]^* (q R_s k / Q)^{i S_l} + c.c. + O(q R_s k / Q) \right\}
\]

(75)
where we recall that \(S_l > 0\) and \(q/Q = \cos \nu\) as in (49). The asymptotic form in the right-hand side of (75) is satisfactory: It is indeed a superposition of solutions of the zero-range model at zero energy, see (35). A first important point is that it is actually a specific linear combination of the solutions with exponents \(s = \pm i S_l\), with relative amplitudes depending on the Feshbach length \(R_s\). This selection of the right linear combination amounts to adjusting the three-body parameter to its right value in the Danilov three-body contact conditions [28]. Eq. (75) thus constitutes a microscopic derivation of this three-body parameter in the limit of an infinitely narrow Feshbach resonance [11, 12]. A second important point is that the solution \(D(k)\) starts approaching the log-periodic oscillatory asymptotic form \((k R_s \cos \nu)^{\pm i S_l}\) as soon as \(k R_s \cos \nu < 1\), there is no need to require that \(k R_s \cos \nu < e^{-2\pi / S_l}\): There is no need to require that the oscillatory form has performed at least one oscillation to have \(D(k)\) well approximated by it.

### IV. ANALYTICAL RESULTS ON TRIMMER STATES

In this central section of the paper, we develop a physical application of the particular analytical solutions of the previous section. From the zero-energy and zero-range solution, we first determine, for each value of the angular momentum \(l\), the critical mass ratio \(\alpha_c^{(l)}\) leading to the Efimov effect and the corresponding purely imaginary Efimov exponent \(s_l = i S_l\), with the convention \(S_l > 0\). Accurate asymptotic estimates for these quantities are obtained and are compared to the Born-Oppenheimer approximation. Second, from a matching of the \((E < 0, R_s = 0)\) solution to the \((E = 0, R_s > 0)\) solution, we determine the Efimovian part of the spectrum, in particular the global energy scale \(E_{\text{global}}^{(l)}\) appearing in that geometric spectrum. The dependence of \(E_{\text{global}}^{(l)}\) on the mass ratio, close to the Efimov threshold \(\alpha \to \alpha_c^{(l)}\) and arbitrarily far from it \((\alpha \to +\infty)\), is studied. Also the variation of \(E_{\text{global}}^{(l)}\) with the angular momentum \(l\), in particular for \(\alpha\) close to the critical mass ratio \(\alpha_c^{(l)}\), is analyzed. Third, using the Born-Oppenheimer approximation expected to be asymptotically exact for a diverging mass ratio, we show that the hydrogenoid character gradually takes over the Efimovian character in that limit, except in a vicinity of the \(E = 0\) accumulation point (which remains Efimovian).

#### A. Efimovian threshold \(\alpha_c^{(l)}\) and exponent \(s_l\)

As a physical application of Eqs. (43,44,46), we determine the values of the mass ratio \(\alpha\) and of the angular momentum \(l\) such that the Efimov effect takes place, that is the transcendental equation \(\Lambda_l(s) = 0\) admits some purely imaginary solutions.

A useful guide is the Born-Oppenheimer approximation [5] that becomes exact in the limiting cases of vanishing or diverging mass ratio \(\alpha\). It indicates that the Efimov effect should take place for large enough values of \(\alpha\) and for odd values of \(l\). It implies that the Efimov threshold \(\alpha \to \alpha_c^{(l)}\) and arbitrarily far from it \((\alpha \to +\infty)\), is studied. Also the variation of \(E_{\text{global}}^{(l)}\) with the angular momentum \(l\), in particular for \(\alpha\) close to the critical mass ratio \(\alpha_c^{(l)}\), is analyzed. Third, using the Born-Oppenheimer approximation expected to be asymptotically exact for a diverging mass ratio, we show that the hydrogenoid character gradually takes over the Efimovian character in that limit, except in a vicinity of the \(E = 0\) accumulation point (which remains Efimovian).
It can be related to the Lambert function by \( C = W(1) \), and it is sometimes called the \( \Omega \) constant. Since the global state vector is fermionic, this extra particle wavefunction can be combined in the Born-Oppenheimer factorized form with an odd orbital fermionic part only. The effective potential seen by the fermions is thus the sum of the Born-Oppenheimer potential \( \varepsilon_0(r_{23}) \) and of the angular momentum centrifugal part \( h^2l(l+1)/(ml_{23}^2) \).

In three dimensions, the zero-energy solution in that effective potential has to be written as \( r_{23}^{-1/2} \) to match the usual definition of the Efimov exponent which is given in two dimensions [44]. We then obtain the Born-Oppenheimer approximation for the root \( s \):

\[
s_{\text{BO}}^2 = \left( l + \frac{1}{2} \right)^2 - \frac{1}{2} \alpha C^2 \quad (l \text{ odd}) \tag{78}
\]

to be used in the regime where \( s_{\text{BO}}^2 \leq 0 \). Interestingly, this Born-Oppenheimer approximation can also be used for a non-zero \( R_s \) to obtain exact results on the non-Efimovian low-energy trimers for \( \alpha \to +\infty \), as developed in subsection IV C.

Turning back to the exact equation \( \Lambda_l(s) = 0 \): For a fixed value of \( l \), we expect that the solutions \( s \) of the transcendental equation are continuous functions of the mass ratio \( \alpha \). The critical values \( \alpha^{(l)}_c \) of \( \alpha \) for the emergence of the Efimov effect are thus such that \( \Lambda_l(0) = 0 \). From a numerical calculation of \( \Lambda_l(s = 0) \) as a function of \( \alpha \) ranging from 0 to \( +\infty \), we indeed find, for even \( l \), that \( \Lambda_l(s = 0) \) has a constant positive sign which means the absence of Efimov effect. For each odd \( l \), we find that \( \Lambda_l(s = 0) \) changes sign once (from positive to negative for increasing \( \alpha \)). The resulting values of \( \alpha^{(l)}_c \) are for example:

\[
\begin{align*}
\alpha^{(1)}_c &= 13.60696 \ldots, \quad \alpha^{(3)}_c = 75.99449 \ldots \\
\alpha^{(5)}_c &= 187.9583 \ldots, \quad \alpha^{(7)}_c = 349.6384 \ldots \tag{79}
\end{align*}
\]

The critical mass ratio for \( l = 1 \) was already given in [5], and in [45] for \( l = 3 \) and \( l = 5 \). For larger \( l \) we have checked that \( \alpha^{(l)}_c C^2/2 \) is indeed very close to the approximation \( l + 1/2 \) resulting from (78). For these few odd values of \( l \), we then solve numerically \( \Lambda_l(iS) = 0 \), where \( S > 0 \), to obtain the Efimov exponent as a function of \( \alpha \) for \( \alpha > \alpha^{(l)}_c \). For each value of \( l \) and \( \alpha > \alpha^{(l)}_c \), it is observed that \( \Lambda_l(iS) \) for \( S > 0 \) is an increasing function of \( S \), so that a single pair of \( \pm iS \) imaginary roots is obtained. The results are shown as solid lines in Fig.2. For comparison, the Born-Oppenheimer approximation (78) is plotted as dashed lines in that figure. As expected intuitively, it approaches the exact result in the large \( l \) (and thus large \( \alpha \)) limit.

One can however be more precise in the evaluation of the accuracy of Eq. (78). For a fixed value \( s_l = iS_l \) of the Efimov exponent, one can perform a large \( l \) expansion of the mass ratio, as shown in Appendix D, to obtain:

\[
\frac{1}{2} C^2 (\alpha - \alpha^{(l)}_c) \xrightarrow{l \to \infty} S_l^2 [1 + O(1/l)] \tag{80}
\]

where the critical mass ratio \( \alpha^{(l)}_c \) has the large \( l \) expansion

\[
\frac{1}{2} C^2 \alpha^{(l)}_c \xrightarrow{l \to \infty} \left( l + \frac{1}{2} \right)^2 + \Delta + O(1/l). \tag{81}
\]

\( \Delta \) is thus the first correction to the critical mass ratio predicted by the Born-Oppenheimer approximation (78). Accidentally it has a very small numerical value [46]:

\[
\Delta = \frac{17 - C^2}{12} - \frac{7}{6} \left( C + \frac{1}{C+1} \right) = -0.016 259 165 \ldots \tag{82}
\]

so that the Born-Oppenheimer approximation for \( \alpha^{(l)}_c \) is in practice quite good for large \( l \). For \( \alpha \to +\infty \) a fixed angular momentum \( l \), one can also obtain from the results of Appendix E the following asymptotic expansion for the imaginary root \( iS_l \) of \( \Lambda_l(s) \):

\[
S_l^2 \sim \frac{C^2}{2} \alpha - \left( l + \frac{1}{2} \right) + \delta + O(1/\alpha) \tag{83}
\]

where the first two terms in the right-hand side constitute the Born-Oppenheimer approximation and the angular-momentum independent constant \( \delta \) is different from zero:

\[
\delta = \frac{5}{12} C^2 + \frac{4}{3} \frac{C^2}{C+1} + \frac{1}{4} = 0.657 684 \ldots \tag{84}
\]

Note that Eq. (83) is not in contradiction with Eq. (80) [combined with Eq. (81)] because the considered limits are totally different, \( S_l/\alpha \) either diverges or vanishes. As \( s^2 \) is a coefficient in the Born-Oppenheimer potential, a suggestive picture obtained from Eq. (83) is that the Born-Oppenheimer approximation has an error \( O(\alpha^0) \) on the effective potential seen by the fermions. Mathematically, Eq. (83) shows that the error on \( S_l \) due to the Born-Oppenheimer approximation vanishes as \( 1/\alpha^{1/2} \), and that the approximation gets the correct leading term \( \alpha^{1/2} \) and the correct subleading term \( \alpha^0 \) (which turns out to vanish) in an asymptotic expansion of \( S_l \) in powers of \( \alpha^{1/2} \). These remarks are useful for subsection IV C.

### B. Efimovian part of the trimer spectrum

In presence of the Efimov effect, we have obtained so far two solutions to the integral equation (34) in limiting cases, see subsection III B for \( R_s = 0, E < 0 \), and subsection III C for \( R_s > 0, E = 0 \). How can we then obtain an approximation for the corresponding spectrum of trimers, which requires to have both \( R_s > 0 \) and \( E < 0 \)?

Roughly speaking, dropping for simplicity a possible dependence on the mass ratio \( \alpha \) of the various bounds, the solution of subsection III B is expected to constitute an accurate approximation of the trimer solution at interparticle distances much larger than \( R_s \), that is at momenta smaller than \( h/R_s \). In a symmetric manner, the solution of subsection III C is expected to well approximate the trimer solution at short enough interparticle...
FIG. 2: Values of the Efimov exponent $s$ as a function of the fermion-to-extra-particle mass ratio $\alpha = m/M$, for several values of the angular momentum $l$. The modulus of $s$ is shown only over the interval of mass ratio $\alpha$ where $s$ is purely imaginary (that is where the Efimov effect takes place). This was found to occur only for odd values of $l$, and for a single pair of $\pm s$ roots of $\Lambda_l(s) = 0$.

FIG. 3: (color online) Matching of two limiting solutions of the integral equation (34), the solution ($E = -\hbar^2 q^2/(2\mu)$) < 0, $R_s = 0$ [see text in black, in the upper half of the figure] given by Eq. (54) and the solution ($E = 0, R_s > 0$) [see text in red, in the lower half of the figure] deducible from Eqs. (29,59,62,70,73), over a common interval of values of $k$ [the “matching interval”, blue segment on $k$ axis] where they are both in their asymptotic regimes Eq. (55) and Eq. (75).

As shown in Appendix C one has the series representation of the phase $\theta_l$, that is we have assumed that the angular momentum $l$ and $|s_l|$ are not much larger than unity.

In this case, we can match the two limiting solutions, as summarized in Fig. 3. Over this matching interval of momentum, one has $k \gg q$ so that the solution of subsection III B is in its large $k$ regime given by (55) with $s = iS_l$. Over this interval, one also has $k < 1/R_s$, so that the solution of subsection III C is in its low-$k$ regime given by (75). These two limiting regimes are compatible (within an arbitrary normalization factor) if $q$ is of the form [47]

$$q_n^{(l)} = q_n^{(l)} e^{-\pi n/|s_l|}, \quad n \text{ integer},$$

where $q_n^{(l)}$ is the Efimov exponent $s_l = iS_l$, $S_l > 0$ and the trimer energy is $E = -\hbar^2 q^2/(2\mu)$, with $\mu = mM/(m + M)$. Eq. (86) is the expected geometric Efimovian spectrum, and we have the explicit expressions for the corresponding global wavenumber and energy scales:

$$q_n^{(l)} = \frac{2}{R_s} e^{\theta_l/|s_l|} \text{ and } E_n^{(l)} = -\frac{2\hbar^2}{\mu R_s^2} e^{2\theta_l/|s_l|}$$

where $\theta_l$ is the phase of the complex number

$$Z_l = |Z_l| e^{i\theta_l} = \prod_{n=1}^l (n - s_l) s_l C_l(-S_l)$$

and the function $C_l(S)$ is given by Eq. (73). At fixed angular momentum, the phase $\theta_l$ depends on the mass ratio $\alpha = m/M$. For $\alpha$ tending from above to the critical value $\alpha^{(l)}$, $S_l \to 0$, we show in the Appendix B that $Z_l$ tends to a real and positive number. We thus choose the usual determination $\theta_l = \text{Arg} \ Z_l$ in that limit, and extend it by continuity to all larger values of $\alpha$.

For the analytical developments that follow, obtained for the global scale $q_n^{(l)}$ in the limit of large angular momenta for $\alpha - \alpha^{(l)}$ fixed, or in the limit of a large mass ratio at fixed angular momentum, there is an actually more operational expression for $\theta_l$, that does not require the determination of all the roots and poles of $\Lambda_l(iS_l)$ to evaluate $C_l(-S_l)$. As shown in Appendix C one has the series representation of the phase $\theta_l$ of $Z_l$.

$$\theta_l = \text{Im} \ln \Gamma(1 + iS_l) + \ln \Gamma(1 + 2iS_l) + 2 \ln \Gamma(l + 1 - iS_l) + \ln \Gamma(l + 2 - iS_l) + \int_{0}^{S_l} ds \ln \left[ \frac{\Lambda_l(iS_l)}{\cos \nu} \frac{S^2 + (l + 1)^2}{S^2 - S^2_l} \right]$$

$$+ \sum_{k \geq 1} \frac{(-1)^k B_{2k}}{(2k)!} \frac{d^{2k-1}}{dS^{2k-1}} \ln \left[ \frac{\Lambda_l(iS_l)}{\cos \nu} \frac{S^2 + (l + 1)^2}{S^2 - S^2_l} \right]$$

$$= \frac{\sin \nu}{\cos \nu} S_l$$

with

$$S_l = l \mu R_s^2$$

and

$$\nu = \ln \left( \frac{2S_l}{\mu R_s} \right)$$

The range of applicability of solution $E = -(\hbar q)^2/2\mu, R_s = 0$ is

$$\text{its asymptotic range:}$$

$$0 \leq q R_s \ll 1$$

The range of applicability of solution $E = 0, R_s > 0$ is

$$\text{its asymptotic range:}$$

$$k \gg q$$

The matching interval is

$$0 \leq q R_s \ll 1/R_s$$

The range of applicability of solution $E = 0, R_s > 0$ for a fixed (purely imaginary) Efimov exponent $s_l$ (as in Efimov’s historical solution) or (less usually) for $|s_l|$ tending to zero at fixed quantum number $n \geq 1$. For simplicity of the figure, we have dropped factors slowly depending on the mass ratio $\alpha$, such as $\cos \nu$, that is we have assumed that the angular momentum $l$ and $|s_l|$ are not much larger than unity.
where we recall that \( S_1 \) is the positive root of the function \( \Lambda_1(iS) \) and the \( B_k \) are Bernoulli’s numbers, \( B_1 = -1/2, B_2 = 1/6, \ldots \) Since (89) was obtained from Stirling’s series, which is an asymptotic series, we expect that (89) is also an asymptotic series. We thus investigated numerically how many terms one has to keep in practice to have a good accuracy. In Fig.4a, it is found remarkably that the zeroth-order approximation, consisting in omitting all the terms in the sum over \( k \) in (89), already gives in practice a sufficiently accurate approximation for the global scale \( q^{(l)}_{\text{global}} \). In Fig.4b, it is shown that the difference between the exact value of \( \theta_l \), obtained from the infinite product representation of \( C_1(-S_1) \), and the zeroth-order approximation, omitting all \( k \) terms in (89), is non-zero but is very accurately accounted for by the term \( k = 1 \) in (89).

From the zero-range theory by Efimov, it is expected that the geometric form Eq. (86) of the spectrum is asymptotically exact in the limit of a large quantum number, \( n \to +\infty \), see the constraint (85). How large the values of \( n \) should be to reach this geometric behavior will be evaluated numerically in section V [in the mean time see the discussion that follows Eq. (91)]. The advantage of the non-zero \( R_c \) calculation is that it also gives the global energy scale in the spectrum, see the factor \( q^{(l)}_{\text{global}} \) in (86) explicitly given by (87). As compared to the bosonic case [11, 12], there is an additional knob here, which is the mass ratio \( \alpha \). How does the global energy scale vary with the mass ratio?

\[ \text{For } \alpha \to \alpha^{(l)}_c : \text{ The behavior of the global energy scale close to the critical mass ratio can be determined from the results of Appendix B, where it is shown that } \theta_l \text{ vanishes linearly with } S_1: \]

\[ \lim_{\alpha \to \alpha^{(l)}_c} \frac{\theta_l}{|S_1|} = -\psi(l+1) + 3\psi(1) - \psi(-iv_0) - \psi(1 - iv_0) + \sum_{n=1}^{\infty} \left[ \psi(-i\nu^n_0) + \psi(1 - i\nu^n_0) - \psi(-iv_0) - \psi(1 - iv_0) \right]. \]

(90)

Here \( v^n_0, n > 0 \), is the value of the complex root \( v_0 \) of the function \( S \to \Lambda_1(iS) \) at the critical mass ratio, the \( v^n = i(2n + l + 1), n \geq 0 \), are the poles of \( S \to \Lambda_1(iS) \), and the function \( \psi(z) \) is the digamma function, that is the logarithmic derivative of the \( \Gamma \) function. As a consequence, the global energy scale has a finite limit at the threshold for the Efimov effect! We give here a few corresponding values obtained from the rapidly converging formula (B6):

\[ q^{(l=1)}_{\text{global}} R_c \simeq 6.56577 \cdot 10^{-2}, \quad q^{(l=3)}_{\text{global}} R_c \simeq 6.12349 \cdot 10^{-3}, \quad q^{(l=5)}_{\text{global}} R_c \simeq 1.62809 \cdot 10^{-3}, \quad q^{(l=7)}_{\text{global}} R_c \simeq 6.48952 \cdot 10^{-4} \]

(91)

At this threshold, \( |s_1| \to 0 \) so we expect that Eq. (86) becomes actually exact for the quantum number \( n \geq 1 \), since \( q^{(l)}_n R_c \) tends to zero in that limit, whereas (86) is clearly invalid for \( n \leq -1 \). The case \( n = 0 \) is dubious: Although \( q^{(l)}_0 R_c \) does not tend to zero at the threshold, it assumes very small values, so may be Eq. (86) still makes sense. We can not however say more at this stage, and the question whether the quantum number \( n = 1 \) corresponds or not to the ground trimer state (for a given angular momentum \( l \)) will be answered in section V.

For \( l \to +\infty \): Another interesting question is to determine how \( q^{(l)}_{\text{global}} \) depends on the angular momentum \( l \) at a fixed distance of the mass ratio \( \alpha \) from the critical value \( \alpha^{(l)}_c \), that is roughly at constant values of the Efimov exponent \( s_1 \). After a numerical evaluation of (87), as detailed in the note [39], we found that \( q^{(l)}_{\text{global}} \) drops rapidly for increasing \( l \), roughly as \( 1/(\alpha^{(l)}_c)^{3/2} \). According to (78) the critical mass ratio scales approximately as \( (l + 1/2)^2 \), so that we expect that \( q^{(l)}_{\text{global}} \) approximately scales as \( 1/(l + 1/2)^{3} \), an approximation that becomes rapidly excellent with increasing \( l \) as soon as \( l \) exceeds unity, see Fig.5.

The scaling of \( q^{(l)}_{\text{global}} \) as \( 1/l^3 \) at a fixed distance from the critical mass ratio can be obtained analytically for \( l \to +\infty \) using the expression (89) for the angle \( \theta_l \) and the expression Eq. (46) for \( \Lambda_1(iS) \), as detailed in the Appendix D:

\[ q^{(l)}_{\text{global}} R_c \to \begin{cases} \frac{(1 + C)}{l^3} \times \exp \left\{ \frac{\ln \Gamma(1 + iS_1) + \ln \Gamma(1 + 2iS_1)}{S_1} \right\} & \text{if } \alpha^{(l)}_c \to 0, \gamma = 0.577 215 664 9 \ldots \text{ is Euler’s constant.} \\
\end{cases} \]

(92)

Here \( C \) is given by Eq. (77) and \( s_1 = iS_1, S_1 > 0 \), and the last, exponential, factor tends to \( \exp(-3\gamma) \) when \( S_1 \to 0 \). \( \gamma = 0.577 215 664 9 \ldots \text{ is Euler’s constant.} \) In that large-\( l \) limit, one can use the Born-Oppenheimer-type relation, \( S_1^2 = (\alpha - \alpha^{(l)}_c)^2/2 \), as shown by Eq. (80). The asymptotic result (92) is plotted as a dashed line in Fig.5 and well reproduces the large-\( l \) numerical results. For \( \alpha \to +\infty \): The behavior of the global energy scale in the limit of an infinite mass ratio (for a given \( l \)) is determined in the Appendix E. It is found that \( q^{(l)}_{\text{global}} \) has a finite limit, which remarkably is also independent of the angular momentum \( l \):

\[ q^{(l)}_{\text{global}} R_c \to 2(1 + C) e^{J} = 3.31582 \ldots \]

(93)

where \( C \) is defined by (77) and \( J \) is the integral

\[ J = \int_{0}^{C} \frac{dx}{\left( \frac{1}{C} \frac{1 + x}{1 - xe^x} - \frac{1}{C - xe^x} \right)} = 0.05630577 \ldots \]

(94)

As we shall see in subsection IV C, for \( \alpha \to +\infty \), the low-lying part of the trimer spectrum is hydrogenoid rather than Efimovian, so that (93) is relevant only for trimers with diverging quantum number \( n \).
served to converge rapidly to a finite limit for increasing \( l = 5 \) and \( l \). The dashed line represents the analytical prediction (92) for the quantity \( \alpha \), as obtained from the exact result (87). The figure shows how the interaction potential on a narrow Feshbach resonance. Then from Schrödinger’s equation for the relative wavefunction of the two fermions,

\[
E\psi(r_{23}) = -\frac{\hbar^2}{m}\Delta r_{23}\psi(r_{23}) + \epsilon(r_{23})\psi(r_{23}) \tag{95}
\]

which is in the odd \( l \) sector due to fermionic antisymmetry, we determine the low-energy trimer states in the limit \( \alpha \to +\infty \).

We first fix the positions of the fermions to \( r_2 \) and \( r_3 \). Each fermion then acts on the extra particle as a fixed scatterer of infinite scattering length, zero true range but finite effective range \( r_e = -2R \). The effect of such a scatterer is then represented by modified contact conditions on the wavefunction \( \phi(r_1) \) of the extra particle in the so-called effective range approach [7, 48]. For a bound state \( \phi(r_1) \) of eigencenery

\[
\epsilon(r_{23}) = \frac{\hbar^2\kappa^2}{2M}, \tag{96}
\]

where the dependence of \( \kappa > 0 \) on \( r_{23} \) is for simplicity omitted in the writing, we impose the boundary conditions

\[
\phi(r_1) \big|_{r_1 = r_n} \sim A_n \left[ \frac{1}{|r_1 - r_n|} - \frac{1}{a_{\text{eff}}} \right] + O(|r_1 - r_n|) \tag{97}
\]

in the vicinity of each scatterer \( n = 2, 3 \). The effective scattering length \( a_{\text{eff}} \) is energy dependent, as \( 1/a_{\text{eff}} = 1/a - k^2r_e/2 \) for an incoming free wave of wavenumber \( k \). Here the true scattering length \( a \) is infinite, the effective range is \( r_e = -2R \), for a narrow Feshbach resonance, and \( k = i\kappa \) is purely imaginary for a bound state, so that \( 1/a_{\text{eff}} = -\kappa^2R_e \). In presence of the contact conditions, the extra-

C. Born-Oppenheimer approximation and hydrogenoid trimer spectrum

As explained in subsection IVA the Born-Oppenheimer approach is a natural tool when the fermions become arbitrarily massive. The extra particle then mediates an attractive interaction potential \( \epsilon(r_{23}) \) between the heavy fermions, with \( r_{23} = r_2 - r_3 \) the relative coordinates of the fermions. We calculate this interaction potential on a narrow Feshbach resonance. Then from Schrödinger’s equation for the relative wavefunction of the two fermions,

\[
E\psi(r_{23}) = -\frac{\hbar^2}{m}\Delta r_{23}\psi(r_{23}) + \epsilon(r_{23})\psi(r_{23}) \tag{95}
\]

which is in the odd \( l \) sector due to fermionic antisymmetry, we determine the low-energy trimer states in the limit \( \alpha \to +\infty \).

We first fix the positions of the fermions to \( r_2 \) and \( r_3 \). Each fermion then acts on the extra particle as a fixed scatterer of infinite scattering length, zero true range but finite effective range \( r_e = -2R \). The effect of such a scatterer is then represented by modified contact conditions on the wavefunction \( \phi(r_1) \) of the extra particle in the so-called effective range approach [7, 48]. For a bound state \( \phi(r_1) \) of eigencenery

\[
\epsilon(r_{23}) = \frac{\hbar^2\kappa^2}{2M}, \tag{96}
\]

where the dependence of \( \kappa > 0 \) on \( r_{23} \) is for simplicity omitted in the writing, we impose the boundary conditions

\[
\phi(r_1) \big|_{r_1 = r_n} \sim A_n \left[ \frac{1}{|r_1 - r_n|} - \frac{1}{a_{\text{eff}}} \right] + O(|r_1 - r_n|) \tag{97}
\]

in the vicinity of each scatterer \( n = 2, 3 \). The effective scattering length \( a_{\text{eff}} \) is energy dependent, as \( 1/a_{\text{eff}} = 1/a - k^2r_e/2 \) for an incoming free wave of wavenumber \( k \). Here the true scattering length \( a \) is infinite, the effective range is \( r_e = -2R \), for a narrow Feshbach resonance, and \( k = i\kappa \) is purely imaginary for a bound state, so that \( 1/a_{\text{eff}} = -\kappa^2R_e \). In presence of the contact conditions, the extra-
particle wavefunction obeys Schrödinger’s equation

$$
\epsilon(r_{23})\phi(r_1) = -\frac{\hbar^2}{2M} \left[ \Delta_{r_1}\phi(r_1) + \sum_{n=2}^{3} 4\pi A_n\delta(r_1 - r_n) \right]
$$

where the Dirac terms are due to the $1/|r_1 - r_n|$ divergences. The general solution is expressed in terms of the Green’s function of the Laplacian at negative energy:

$$
\phi(r_1) = \sum_{n=2}^{3} A_n e^{-\kappa r}\frac{\delta(r_1 - r_n)}{|r_1 - r_n|}.
$$

The contact conditions (97) then impose $(1 + \kappa R_\ast)A_{2,3} = A_{3,2}e^{-\kappa r_{23}}/(\kappa r_{23})$. This $2 \times 2$ system has a non-zero solution only for the symmetric case $A_2 = A_3$, where $\kappa$ solves

$$
1 + \kappa R_\ast = e^{-\kappa r_{23}}\frac{1}{\kappa r_{23}}.
$$

The wavefunction $\phi(r_1)$ is then symmetric under the exchange of $r_2$ and $r_3$. As the Born-Oppenheimer ansatz for the total wavefunction is $\psi(r_{23})\phi(r_1; r_2, r_3)$, where the parametric dependence of $\phi$ with the fermions positions is made explicit, fermionic exchange symmetry indeed imposes $\psi(-r_{23}) = -\psi(r_{23})$.

For a fixed $r_{23}$, Eq. (100) looks difficult to solve. However, one can see that, for each positive $\kappa$, it is solved by a single positive $r_{23}$ [49]. Furthermore, rewriting $\kappa$ in the left hand side as $(\kappa r_{23})/r_{23}, r_{23}/R_\ast$ may be expressed as an explicit function of $u = \kappa r_{23}$, where $u$ ranges from 0 to the numerical constant $C$ defined in (77):

$$
r_{23} = \frac{u^2}{e^{-u} - u}.
$$

This allows a straightforward plot and study of the Born-Oppenheimer potential $\epsilon(r_{23})$. We reach in particular the useful limiting cases

$$
\epsilon(r_{23}) \sim \frac{\hbar^2 C^2}{2M r_{23}^2}
$$

$$
\epsilon(r_{23}) \sim \frac{\hbar^2}{2MR_\ast^2} \left( \frac{R_\ast}{r_{23}} - \frac{2R_\ast^{1/2}}{r_{23}^{1/2}} + O(1) \right)
$$

The asymptotic behavior (102) reproduces the Born-Oppenheimer potential (76) obtained for the usual Bethe-Peierls case $R_\ast = 0$. For a large enough $\alpha$, and for each odd values of the angular momentum $l$, it ensures that the spectrum of Eq. (95) is indeed Efimovian in the limit of large quantum number $n$, that is for $E \to 0^-$. On the contrary, for fixed quantum numbers $n$ and $l$, the bound states of (95) for increasing $\alpha = m/\mathcal{M}$ are increasingly localized in the low $r_{23}$ part Eq. (103) of the Born-Oppenheimer potential. This means that the low-energy part of the spectrum is hydrogenoid, it becomes asymptotically equivalent for large $\alpha$ to the known spectrum of the hydrogen atom if one takes for the electron mass $m_e = m/2$ and the CGS electron charge $e$ such that $\epsilon^2 = \hbar^2/(2MR_\ast)$. In terms of the wavenumber $q$ introduced in Eq. (26) we thus obtain the exact asymptotic result [50]

$$
q_n^{(l)} R_\ast \sim \frac{(\alpha/8)^{1/2}}{n + 1} \left[ 1 - R_\ast^{(l)} \left( \frac{\pi(n + l)}{2\alpha} \right)^{1/2} + O\left( \frac{1}{\alpha} \right) \right],
$$

where $R_\ast^{(l)}$ is a rational number given by

$$
R_\ast^{(l)} = \frac{(n - 1)!}{(n + 2)!} \sum_{k=0}^{n-1} \frac{(2k)!}{(k)!^2} \frac{1}{(2k + l - 1)!} \frac{1}{(2k + l - 1)!} \times \frac{[2(2l + 1 + n - k)]!}{(n - 1)![(2l + 1 + n - k)!].
$$

An interesting question is to know whether Eq. (105), that originates from the Born-Oppenheimer approximation, is still exact [51]. The discussion below Eq. (84) allows to hope so. We shall present numerical evidence in subsection VC that this is indeed the case.

Another interesting aspect is to determine if the Born-Oppenheimer approximation, combined with a suitable semi-classical (WKB) type approximation, is able to determine exactly the global scale $q_n^{(l)}$ in the large mass ratio limit. For a fixed angular momentum $l$, using the technique presented in [52] and setting here $E = -\hbar^2 Q^2/m$, we obtain the semi-classical quantization condition [53]

$$
\int_{r_{23,\min}}^{r_{23,\max}} dr \left( \frac{\alpha^2}{2} \left( r - \frac{l + 1/2}{r} - \frac{Q^2}{r^2} \right)^2 \right)^{1/2} = (n - 1/2)\pi
$$

where $r_{23,\min}$ and $r_{23,\max}$ are the lower and upper roots of the integrand, and the quantum number $n$ is any integer $\geq 1$. In the large $n$ limit, $Q$ tends to zero exponentially fast (this is the Efimovian part of the spectrum), so that we can split the integral in (107) in two intervals, the interval $r_{\min} < r < r_{\text{int}}$ where one can make the approximation $Q \simeq 0$, and the interval $r_{\text{int}} < r < r_{\max}$ where the Born-Oppenheimer potential can be replaced by its asymptotic expression (102). The intermediate value $r_{\text{int}}$ simply has to satisfy $R_\ast < r_{\text{int}} < |s_{BO}|/Q$ where $s_{BO}$ is given by Eq. (78). Then the result does not depend on...
the specific value of $r_{\text{int}}$ and one finds an approximation for the Efimovian spectrum for $n \rightarrow +\infty$:

$$q_n^{(l)} R_s \approx \frac{2^{3/2}|s_{\text{BO}}|(C - u_{\text{min}})(1 + C)}{C^2(1 + \alpha)^{1/2}} e^{J_d \epsilon_{\text{cl}} - (n-1/2)\pi|/|s_{\text{BO}}|},$$

(108)

where we have performed the change of variable $u = \kappa(r)r$ in the integral over $r$ and one has $\alpha q_{\text{min}}^2/2 = (1 + 1/2)^2$. The quantity $J_d$ is defined by the integral

$$J_{\text{cl}} = -1 + \int_{u_{\text{min}}}^{C} du \left[ \left( \frac{2}{u} + \frac{e}{1 - u} \right) \left( \frac{u^2 - u_{\text{min}}^2}{C^2 - u_{\text{min}}^2} \right)^{1/2} - \frac{1}{C - u} \right].$$

(109)

Whereas as expected [53] this semi-classical result is disastrously bad for $\alpha$ close to the critical value $\alpha_{c}^{(l)}$ (it does not predict a finite $q_{\text{global}}^{(l)}$ at the Efimovian threshold), it becomes increasingly accurate for increasing $\alpha - \alpha_c^{(l)}$. Comparing to the exact numerical values of Fig.4a, we found that for $\alpha = \alpha_c^{(l)} > 8$, the error on $q_{\text{global}}^{(l)}$ is already less than 10%. In the limit $\alpha \rightarrow +\infty$, the semi-classical result allows to recover exactly the quantum result Eq. (93), since $u_{\text{min}} \rightarrow 0$ in that limit and $J_d$ then tends to $J$ of Eq. (94). Keeping the first correction linear in $u_{\text{min}}$ in the semi-classical result we even get the refined estimate

$$q_{\text{global}}^{(l)} R_s \approx 2(1 + C) e^{J} \left[ 1 - \frac{\pi l}{|s_{\text{BO}}|} + O(\ln \alpha/\alpha) \right].$$

(110)

As this amount to keeping the first $\alpha^{-1/2}$ term in a large $\alpha$ expansion, we can again hope that the Born-Oppenheimer approximation (combined to the semi-classical one) gives the exact result in Eq. (110) [54]. In Fig.4c we have calculated $J_{\text{cl}}$ and hence the semi-classical value of $q_{\text{global}}^{(l)}$ numerically to show how it nicely interpolates between the large-$\alpha$ exact data of Fig.4a (that still strongly depend on $l$) and the $l$-independent $\alpha \rightarrow +\infty$ limit of $q_{\text{global}}^{(l)}$. Taking values of $\alpha$ as large as in Fig.4c is straightforward in the semi-classical formula, but it would be a numerical challenge for the exact expression Eq. (73) (not to mention real experiments).

V. NUMERICAL SOLUTION FOR TRIMER STATES

In this section, we proceed with the direct numerical solution of the integral equation (34), looking for the allowed bound state energies $E$ for various values of the angular momentum quantum number $l$. The motivation is to look for trimer states that are not predicted (or not faithfully predicted) by the analytical results of section IV. First, in presence of the Efimov effect ($l$ odd, $\alpha > \alpha_c^{(l)}$) the analytical formula (86) is guaranteed to be asymptotically exact in the large quantum number $n \rightarrow +\infty$ limit, but the numerics can assess its accuracy for low values of $n$, $n \geq 1$, and can check whether or not $n = 1$ in (86) corresponds to the ground state trimer for a given angular momentum. Second, it is in principle possible that the narrow Feshbach resonance model exhibits for $1/\alpha = 0$ non-Efimovian trimers, that would appear for a mass ratio lower than $\alpha_c^{(l)}$. In single channel models, with real interaction potentials, such few-body bound states were recently observed numerically [55, 56] and their emergence was related to few-body resonances [56] that one may expect within the zero-range model when Eq. (36) has a real root $s$ between 0 and 1 [27, 57]. To be complete, let us mention that, for a finite and positive value of the scattering length, we expect that they exist a finite number of non-Efimovian $l = 1$ trimers for mass ratios below the critical mass ratio $\alpha_c^{(l = 1)}$, as shown in [58]. These interesting trimer states should have a vanishing energy right at the Feshbach resonance ($1/\alpha = 0$) so that they shall not show up in our numerical solution and their study is beyond the scope of the paper.

A. Optimized numerical method

The general method to numerically find the bound state spectrum is to approximate the operator appearing in the momentum space integral equation by a matrix, after discretization and truncation of the momentum $k$, and to perform a dichotomic or Newton search of the values of the energy $E < 0$ such that the resulting matrix has a zero eigenvalue. Here, we are in the particular case of an infinitely narrow Feshbach resonance with an infinite scattering length, and a much more direct method can be used. The kernel in (34) does not indeed involve any interaction length, it exhibits $hq$ as the only momentum scale, where the wavenumber $q$ is the unknown since $E = -h^2q^2/(2\mu)$. We can thus rescale all wavenumbers by $q$, setting $k = k/q, K = K/q$, and we introduce a reduced relative wavenumber

$$\hat{q}_{\text{rel}}(\hat{k}) \equiv \frac{q_{\text{rel}}(k\hat{k})}{q} = \left[ 1 + \frac{1 + 2\alpha}{(1 + \alpha)^2} \hat{k}^2 \right]^{1/2}.$$  

(111)

For convenience, we also write the unknown function $f^{(l)}(k)$ as

$$f^{(l)}(k = q\hat{k}) = \frac{\hat{J}^{(l)}(\hat{k})}{k\hat{q}_{\text{rel}}(\hat{k})}.$$ 

(112)

where the denominator shall ensure that the resulting integral operator is hermitian. After multiplication of
so as to ensure that the effective range term in the two-body scattering amplitude is well taken into account. For a given numerical diagonalization, the negative eigenvalues $-qR_*$ that are larger than $-1/k_{\text{max}}$ thus cannot be trusted. In these estimates, we have dropped for simplicity a possible dependence of the criteria on the mass ratio $\alpha$ [59].

In presence of the Efimov effect, the condition (114) is quite severe, as $qR_*$ may assume extremely small values. The way out is well known, one simply has to use a logarithmic scale, with the change of variable $x = \ln k, X = \ln K$. To keep the hermiticity of the operator, we reparametrize the unknown function

$$f^{(l)}(k = e^x) = \frac{F^{(l)}(x)}{e^{x/2}}.$$  \hfill (115)

Multiplying (113) by $k^{1/2}$ and performing these changes, we finally obtain the numerically useful form [60]:

$$-qR_* F^{(l)}(x) = \frac{F^{(l)}(x)}{(1 + e^{2x} \cos^2 \nu)^{1/2}} \int_{-\infty}^{+\infty} \frac{dX}{\pi} \frac{F^{(l)}(X)}{[(1 + e^{2x} \cos^2 \nu)(1 + e^{2X} \cos^2 \nu)]^{1/2}} \int_{-1}^{1} \frac{P_1(u)e^{(x+X)/2}}{1 + e^{2x} + e^{2X} + 2ue^{x+X} \sin \nu} du$$

where we recall that $\nu = \arcsin[\alpha/(1 + \alpha)]$, see (39). Another interesting feature of the form (116), that it shares with (113), is that the kernel remains bounded at large momenta.

### B. Efimovian results

We now present results obtained from a numerical solution of the eigenvalue problem (116), for not too large values of the mass ratio so that the trimer spectrum does not exhibit the hydrogenoid character predicted in subsection IV.C. In the numerics, we took for the variable $x = \ln k$ a discretization with a constant step $dx = 0.09$ over an interval from $x_{\text{min}} = \ln (10^{-2})$ to $x_{\text{max}} = \ln (10^{15})$. We explored the interval of mass ratio $\alpha = m/M$ from the small value 1/200 to the large value 200.

We first explored the case of even angular momenta. According to the zero-range theory, numerical observation of bound states in that case would reveal non-Efimovian trimers. We went up to an angular momentum $l = 12$ without finding any bound state: The minimal eigenvalues $-qR_*$ found numerically were positive and of the order of $10^{-15}$ or larger. We then explored odd angular momenta, looking for non-Efimovian bound states for a mass ratio $\alpha < \alpha_0^{(l)}$ (and $\alpha < 200$). We went up to $l = 13$ without finding any.

At this stage, it remained to explore Efimovian physics. The numerical results for the most bound trimer states are shown for $l = 1$ in Fig.6. In Fig.6a we directly show the obtained values of $qR_*$ as functions of the mass ratio $\alpha$, obviously in log scale for the vertical axis. This is useful to estimate which trimer states may be accessed in an experiment. An experimental limitation is that the scattering length $a$ is not infinite, which will suppress the too-weakly bound trimers, that is the trimer states with a too small value of $q$. According to (28) we see that if $1/|a| \ll q$, the term 1/|a| is small as compared to the term $q_{\text{rel}}(k)$ for all values of $k$, so that the assumption $1/|a| = 0$ should be a good approximation. Assuming that producing in a controlled way a scattering length larger than 100 $\mu$m (in absolute value) becomes unrealistic, in particular for a narrow Feshbach resonance, we thus take

$$|a^{\text{exp}}| \leq 100 \mu m$$  \hfill (117)

and we impose $q > 10/|a| \approx 10/(100 \mu m)$. Since $R_*$ should be much larger than the typical van der Waals length (typically of a few nanometers), we take $R_* > 10$ nm, so that $qR_* > 10^{-2}$. Hence the interval of values on the vertical axis in Fig.6a [61].

In the more theoretical Fig.6b, we show the ratios of the numerical values of $qR_*$ to the values obtained from the approximation (86), as functions of the mass ratio. The numerical values are numbered as $n = 1$...
(ground state trimer state), \( n = 2, 3, \ldots \), for \( q \) in descending order (that is in ascending order of the energies \( E_n = -\hbar^2 q_n^2/2\mu \)). The numerical \( q_n \) are then each divided by the approximate \( q_n \) of (86). For \( \alpha \) close to \( \alpha_c^{(l=1)} \), for example \( \alpha \leq 20 \), it is found that the ratio of numerical to analytical values of the \( q's \) is extremely close to unity: For the ground trimer \( n = 1 \), the deviation is less than \( 10^{-3} \), and for \( n = 2 \) and \( n = 3 \) it is fluctuating between \( \pm 10^{-5} \) which is probably due to numerical errors. Similar results are obtained for larger odd values of \( l \) (not shown).

We have thus numerically obtained the important result that the quantum number \( n = 1 \) in the analytical formula (86) indeed corresponds to the ground trimer state (within each subspace of fixed \( l \)). For \( \alpha = \alpha_c^{(l)} \), not too large (away from the hydrogenoid regime), the binding energy of the ground trimer state thus does not correspond to the naive expectation \( \approx h^2/(\mu R_s^2) \), it contains an extra factor \( \exp(-2\pi/|s_1|) \) which can be tiny. There is numerical evidence that this also holds for three bosons resonantly interacting on a narrow Feshbach resonance [41]; the impossibility in the bosonic case to connect the spectrum continuously to a \( S_l = 0 \) limit (and to study the variation of the three-body parameter in that limit) however makes the statement more subjective than in the present fermionic case.

To be complete, we have also calculated numerically the eigenvectors \( x \rightarrow \hat{F}^{(l)}(x) \) corresponding to the eigenvalues \( -q_n^{(l)} R_s \), in the case \( l = 1 \) for \( \alpha = 14 \). According to Eqs. (112,115) one has \( \hat{F}^{(l)}(x) = e^{x^2/2}(1 + e^{2x}\cos^2\nu)^{1/2}f^{(l)}(q e^x) \). For \( k/Q \ll 1 \), that is \( e^x\cos\nu \ll 1 \) since \( Q = q/\cos\nu \), we found that \( \hat{F}^{(l=1)}(x) \propto e^{x^2/2} \) as deduced from (54) [multiplied by \( i \)]. For \( kR_s \cos\nu \gg 1 \), that is \( e^x\cos\nu \gg e^{\pi n/|s_1|} \), where \( s_1 = iS_1 \) is the purely imaginary Efimov exponent for \( l = 1 \), we found that \( \hat{F}^{(l=1)}(x) \propto e^{-5x^2/2} \) as predicted by [42]. Finally, in the crucial intermediate region \( q/\cos\nu \ll k < 1/(R_s \cos\nu) \), which corresponds to the matching interval of the \((E < 0, R_s = 0) \) and \((E = 0, R_s > 0) \) analytical solutions, see Fig.3, we compared the numerics to the analytical result deduced from Eq. (55) [multiplied by \( i \)]:

\[
\hat{F}^{(l=1)}(x) \propto e^{x^2/2} \sin[|s_1|(x - x_0)]
\]

where \( x_0 = (\arctan |s_1|)/|s_1| - \ln(2\cos\nu) \). From the numerics, see Fig.7, we found that \( x \rightarrow e^{-x^2/2} \hat{F}^{(l=1)}(x) \) indeed exhibits half an oscillation of the sinus for the ground trimer \( n = 1 \) [the function remains positive everywhere], and a full oscillation of the sinus for the first excited trimer \( n = 2 \) [the function changes sign once].

These nodal properties were expected from the fact noted in [60] that the matrix elements of the kernel in (116) are strictly negative for \( l \) odd, for all \( x \) and \( X \), whereas the diagonal element is strictly positive, for all \( x \). From a standard variational argument, that formulates Eq. (116) in terms of the extremalization of an “energy” functional for a fixed norm, and that compares the “energy” of \( x \rightarrow \hat{F}^{(l)}(x) \) to the one of \( x \rightarrow |\hat{F}^{(l)}(x)| \), we conclude that the function \( \hat{F}^{(l)}(x) \) for the ground trimer state has a constant sign. As the other modes have to be orthogonal to the ground mode, this shows that the ground trimer state is not degenerate, and that the excited trimer states have a sign-changing function \( \hat{F}^{(l)}(x) \). We have thus reached a fully consistent picture of the fact that \( n = 1 \) in Eq. (86) is indeed the ground trimer state.

C. Hydrogenoid results

We now explore numerically the trimer spectrum for extremely large values of the mass ratio \( \alpha \). In this limit, the low-energy trimers are not expected to be Efimovian anymore: According to the Born-Oppenheimer approach of subsection IV-C, the spectrum for fixed values of the quantum numbers \( n \) and \( l \) becomes hydrogenoid for \( \alpha \rightarrow +\infty \). To test the asymptotic analytical formula (105), we plotted in Fig.8 the ratio of the wavenumber \( q_n^{(l)} \) [such that \( E_n^{(l)} = -h^2(q_n^{(l)})^2/(2\mu) \)] to the asymptotic prediction (104) as a function of \( 1/\alpha^{1/2} \), for \( l = 1 \) and a few values of \( n \) (we recall that \( n = 1 \) labels the ground trimer state for fixed \( l \)). The prediction Eq. (105) then corresponds to straight lines, and we indeed observe that the numerical results approach these straight lines for diverging \( \alpha \). This suggests that (105), obtained in the Born-Oppenheimer approximation, is actually asymptotically exact. As expected, for increasing \( n \), the trimers become spatially more extended, so that a larger value of \( \alpha \) is required to make them hydrogenoid.

Some considered values of \( \alpha \) in Fig.8 are extremely large, up to \( 10^6 \). This can not be realized with atoms, as such a large mass ratio does not exist in the periodic table. Using an optical lattice as suggested in [62] is possible if the trimer states have a spatial extension much larger than the lattice spacing. This may require here unrealistically large values of \( R_s \). A futuristic alternative is to replace the fermionic atoms by large and round molecules, cooled to their internal (vibrational and rotational) ground state, that have a vanishing total angular momentum in that ground state, may be in the class of fullerenes [63], and that would exhibit a narrow Feshbach resonance with the extra atom.

VI. CONCLUSION

We have performed a detailed study of the quantum three-body problem of two same-spin-state fermions of mass \( m \) interacting in free space with a distinguishable particle of mass \( M \) on an infinitely narrow Feshbach resonance, with a focus of the three-body bound states (trimer states) of that system. The interaction was assumed to be tuned right on resonance, with an infinite \( s \)-wave scattering length \( a \), which makes it possible to obtain analytical results, since the only length scale left in the problem is the so-called Feshbach length \( R_s \) [7]. The assumption \( 1/a = 0 \) also ensures that there is no
two-body bound states. This three-body problem however remains rich, richer than e.g. the problem of three resonantly interacting bosons on a narrow Feshbach resonance [7, 11, 12], because there is a tunable parameter left, which is the mass ratio $\alpha = m/M$ of a fermion to the extra particle. The existence of this tunable parameter raises the following three fundamental questions on the trimer states within each sector of fixed total angular momentum $l$.

First, does this system support trimer states for a mass ratio $\alpha$ smaller than the minimal mass ratio $\alpha_c$ required to activate the Efimov effect [4]? Such non-Efimovian trimer states may indeed emerge from three-body resonances recently discovered numerically for a different interaction model [55, 56], with an Efimov exponent $s$ having a real value between 0 and 1 [27, 57]. For the

FIG. 6: Numerical study of the Efimovian part of the spectrum: For an angular momentum $l = 1$, quantities $q_n$ (labeled in descending order) from $n = 1$ (ground trimer state) to $n = 8$, as functions of the mass ratio $\alpha = m/M$. We recall that the trimer energies are then $E_n = -\hbar^2 q_n^2 / 2\mu$. In (a) the numerical values are shown in log scale, restricting the figure to experimentally accessible values $qR_*$ larger (respectively smaller) than the analytical ones. For both (a) and (b), the vertical axis is in log scale, and the curves $n = 1$ to $n = 8$ are from top to bottom.

FIG. 7: For $l = 1$ and a mass ratio $\alpha = 14$, ground eigenvector ($n = 1$) and first excited eigenvector ($n = 2$) of the eigenvalue problem Eq. (116), corresponding to the ground and first excited trimer states. Solid lines: Numerical results. Dashed lines: Analytical form (118), meaningful over the matching interval $1/(\cos \nu < k/q < 1/(qR_\ast \cos \nu)$ whose meaning is explained in Fig.3 and whose borders are indicated by the vertical dotted lines. The expression of $D(k)$ in terms of $\mathcal{F}^{(1)}(x)$ and $Y_0^0(k)$ can be obtained from the text, with $x = \ln(k/q)$. An overall factor $\exp(-x/2)$ was applied to $\mathcal{F}^{(1)}(x)$ for convenience, and the resulting functions are normalized to the maximal value of unity.

FIG. 8: (color online) Numerical study of the hydrogenoid part of the spectrum: For an angular momentum $l = 1$, wavenumbers $q_n(l)$ for $n = 1$ (ground trimer state), $n = 2$, $n = 3$ and $n = 4$ (from top to bottom), divided by the hydrogenoid asymptotic Born-Oppenheimer prediction (104), as functions of $1/\alpha^{1/2}$. Disks: Numerical results. Straight lines: Asymptotic result (105) including the first deviation of the Born-Oppenheimer potential from the Coulomb form at short range. The color code is black for $n = 1$, red for $n = 2$, green for $n = 3$ and blue for $n = 4$.
narrow Feshbach resonance, our numerical answer to this question is negative.

Second, how does the Efimov trimer spectrum emerge when the mass ratio \( \alpha \) is varied across the critical value \( \alpha_c \) (necessarily for \( l \) odd)? This is an intriguing question, because there is no trimer state for \( \alpha < \alpha_c \) (for fixed \( l \)) and there is an infinite number of trimer states for \( \alpha > \alpha_c \). We found that, for \( \alpha \) tending to \( \alpha_c \) from above, the whole trimer spectrum, including the ground trimer state (and not simply the trimer states \( \alpha \)) for \( \alpha > \alpha_c \) vanishes as \( E \) as the square root of \( m \) threshold, the energy of the ground state trimer vanishes as the square root of \( \alpha - \alpha_c \). This constitutes a complete picture of the emergence of the Efimovian trimer states when the mass ratio is varied across \( \alpha_c \).

The dependence of \( E_{\text{global}} \) on the mass ratio \( \alpha \) and on the angular momentum \( l \) was further studied analytically, by an efficient and to our knowledge original expression of \( E_{\text{global}} \) in terms of an asymptotic series, see Eqs. (87,89).

Third, what is the nature of the most bound trimer states, for example the ground state, when the mass ratio \( \alpha \) becomes significantly larger than the critical value \( \alpha_c \)?

As already mentioned, Efimov’s theory cannot answer this model-dependent question. For the narrow Feshbach resonance, we found that, for \( \alpha \) tending to \( \alpha_c \) from above, the whole trimer spectrum, including the ground trimer state (and not simply the trimer states \( \alpha \)) for \( \alpha > \alpha_c \) vanishes as \( E \) as the square root of \( \alpha - \alpha_c \). This constitutes a complete picture of the emergence of the Efimovian trimer states when the mass ratio is varied across \( \alpha_c \).

The dependence of \( E_{\text{global}} \) on the mass ratio \( \alpha \) and on the angular momentum \( l \) was further studied analytically, by an efficient and to our knowledge original expression of \( E_{\text{global}} \) in terms of an asymptotic series, see Eqs. (87,89).

The dependence of \( E_{\text{global}} \) on the mass ratio \( \alpha \) and on the angular momentum \( l \) was further studied analytically, by an efficient and to our knowledge original expression of \( E_{\text{global}} \) in terms of an asymptotic series, see Eqs. (87,89).

We warmly thank L. Pricoupenko and C. Mora for fruitful discussions at an early stage of this work, A. Sinatra for useful comments on the manuscript, and F. Werner for pointing out useful references. The group of Y.C. is a member of IFRAF.

Appendix A: Zero-range solution in position space

In the case \( R_s = 0 \), our three-body problem reduces to the zero-range infinite scattering length problem that Efimov solved in real space [4] with the ansatz for the three-body wavefunction:

\[
\psi(r_1, r_2, r_3) = \frac{F(R)}{R^2} \left[ \frac{\varphi(\alpha_2)}{\sin(2 \alpha_2)} Y^m_l \left( r_3 - \frac{\alpha r_2 + r_1}{1 + \alpha} \right) - \frac{\varphi(\alpha_3)}{\sin(2 \alpha_3)} Y^m_l \left( r_2 - \frac{\alpha r_3 + r_1}{1 + \alpha} \right) \right]. \tag{A1}
\]

This contains two a priori unknown functions of single variables, \( F \) and \( \varphi \). The various variables in this ansatz naturally appear in appropriately normalized Jacobi coordinates. Using e.g. the convention of Appendix 3 in [29] (except for a permutation of the indices), taking as in Eq. (13) particle 1 as the extra particle of mass \( m_1 = M \), and 2 and 3 as the fermions of mass \( m_2 = m_3 = m \), we define the unnormalized Jacobi coordinates \( y_1 = r_3 - (m r_2 + M r_1)/(m + M) \) and \( y_2 = r_1 - r_2 \), the generalized reduced masses \( \mu_1 = m - 1 + (m + M)^{-1} \) and \( \mu_2 = M^{-1} + m^{-1} \), the hyperradius \( R \geq 0 \) such that \( m R^2 = \sum_{i=1}^3 m_i (r_i - C)^2 \) where \( C \) is an arbitrary unit of mass and \( C \) is the center of mass position of the three particles. Then the conveniently normalized Jacobi coordinates are \( u_i = (\mu_i/m_i)^{1/2} y_i \) with \( i = 1, 2 \), so that \( R^2 = u_1^2 + u_2^2 \). This also puts Schrödinger’s equation in a reduced form,

\[
\sum_{i=1}^3 \frac{\hbar^2}{2m_i} \Delta r_i = - \frac{\hbar^2}{2(m + M)} \Delta C + \sum_{i=1}^2 \frac{\hbar^2}{2m_i} \Delta u_i. \tag{A2}
\]
The angles $\alpha_{21}$ and $\alpha_{31}$ belong to the interval $[0, \pi/2]$. The clever choice is $\tan \alpha_{21} = u_2/u_1$ and the similar formula for $\alpha_{31}$ obtained by exchanging the role of particles 2 and 3. Geometrically, this amounts to introducing polar coordinates $(R, \alpha_{21})$ in the plane $(u_1, u_2)$. Explicitly this gives

$$\tan \alpha_{21} = \frac{|r_1 - r_2| \cos \nu}{|r_3 - (\alpha r_1 + r_1)/(1 + \alpha)|}$$  \hfill (A3)

$$\tan \alpha_{31} = \frac{|r_1 - r_3| \cos \nu}{|r_2 - (\alpha r_3 + r_1)/(1 + \alpha)|}$$  \hfill (A4)

where $\cos \nu$ is given by (40). Since the second (Faddeev) component in (A1) is deduced from the first one by a minus sign and the exchange of particles 2 and 3, which ensures the fermionic antisymmetry of $\psi$, it suffices to calculate the action of $\Delta_{u_1} + \Delta_{u_2}$ on the first component. This is quite simple in spherical coordinates, since $R$ and $\alpha_{21}$ depend only on the moduli $u_1$ and $u_2$, and the factor involving the spherical harmonic function is simply $Y^m_l(u_1)$. Thanks to the factor $R^2 \sin(2\alpha_{21}) = 2u_1u_2$ in the denominator, one is left with the operator $\partial^2 / \partial r^2$, that is the Laplacian in the plane $(u_1, u_2)$, which has a simple expression in the polar coordinates $(R, \alpha_{21})$. One finally finds that the ansatz (A1) separated in hyperspherical coordinates solves Schrödinger’s equation if $\varphi$ solves the eigenvalue problem

$$-\varphi''(\alpha_{21}) + \frac{l(l+1)}{\cos^2 \alpha_{21}} \varphi(\alpha_{21}) = s^2 \varphi(\alpha_{21}).$$  \hfill (A5)

$s$ is a priori unknown, but the general theory of e.g. section 3.3 in [29] guarantees that it coincides with $s$ defined in Fourier space by (35). As a consequence, the $R$ dependence of the ansatz also separates and the hyperradial function $F(R)$ is found to solve a Schrödinger equation for a fictitious particle in two dimensions experiencing an effective $1/R^2$ potential:

$$EF(R) = -\frac{\hbar^2}{2m} \left[ F''(R) + \frac{1}{R} F'(R) \right] + \frac{\hbar^2 s^2}{2mR^2} F(R).$$  \hfill (A6)

The Efimov effect appears for $s^2 < 0$.

To determine the eigenvalue $s^2$, one needs to specify the boundary conditions for $\varphi$. For $u_1 \to 0$, $\psi$ in general does not diverge. Since $\sin(2\alpha_{21})$ vanishes in the denominator, this imposes

$$\varphi(\pi/2) = 0. \hfill (A7)$$

For $u_2 \to 0$, on the contrary, $\psi$ diverges. More precisely, the Bethe-Peierls contact conditions for an infinite scattering length impose that, when particles 1 and 2 approach each other for a fixed position of their center of mass $C_{12}$, that is $r_2 = C_{12} - r_1/(1 + \alpha)$ and $r_1 = C_{12} + \alpha r_1/(1 + \alpha)$ with $r \to 0$, $\psi$ should behave as $A/r + O(r)$ where $A$ depends here on $C_{12} - r_3$. In other words, there should be no non-zero contribution behaving as $r^0$. To calculate the $r^0$ contribution from the first Faddeev component, one has to expand $\varphi(\alpha_{21})$ to first order in $\alpha_{21}$. In the second Faddeev component one can directly set $r = 0$, that is $r_1 = r_2 = C_{12}$. From the angular representation (39) for the mass ratio, we find $\arctan[(1 + 2\alpha)^{1/2}/\alpha] = \frac{\pi}{2} - \nu$ and

$$\frac{1}{2} r^0(0) - (-1)^s \frac{\varphi(\nu)}{\varphi(0) \sin \nu} = 0. \hfill (A8)$$

To try to recover the function $\Lambda_i(s)$, we heuristically multiply this condition by $2 \cos \nu/\varphi(0)$ to pull out a first additive term as in (44):

$$\Lambda_i(s) \equiv \cos \nu - (-1)^s \frac{\varphi(\nu)}{\varphi(0) \sin \nu}. \hfill (A9)$$

Note that Eq. (A5) is independent of the mass ratio, it occurs in the problem of three spin $1/2$ (same mass) fermions and even in the case of three bosons. The solution of (A5) obeying (A7) was given in these contexts in [32] in terms of a hypergeometric function. Reusing this solution

$$\varphi(\alpha_{21}) = \cos^{l+1} \alpha_{21} \left( l + 1 + s \right) \left( 1 + l - s \right) \left( l + 1 + s + 1 \right) \cos^2 \alpha_{21}$$

leads to (46) that was checked numerically to coincide with (44), so that the question mark can be removed in (A9). For completeness, we note that still another form of $\varphi(\alpha_{21})$, in terms of a finite sum, was given in [30].

**Appendix B: Efimovian spectrum global scale at threshold**

At fixed angular momentum $l$, we evaluate the global scale $q^{(l)}_{\mathrm{global}}$ in the limit $\alpha \to \alpha^{(l)}_c$. Since $s_l = iS_l$, $S_l > 0$, vanishes in that limit, we can simply expand the complex number $Z_l$ up to order $S_l$, neglecting terms $O(S_l^2)$. The most difficult part is the bit $iS_l C_l(-S_l)$, that we rewrite using (73), $\Gamma(2iS_l) = \Gamma(1 + 2iS_l)/(2iS_l)$:

$$iS_l C_l(-S_l) = \frac{\Gamma(1 + 2iS_l)\Gamma(1 - iv_0 - iS_l)}{2\Gamma(1 - iv_0 + iS_l)} \times \prod_{n \in \mathbb{N}^*} \frac{\Gamma(-iv_0 + iS_l)}{\Gamma(-iv_0 + iS_l)} \frac{\Gamma(1 - iv_n - iS_l)}{\Gamma(1 - iv_n - iS_l)}. \hfill (B1)$$

We first need to figure out to which order the roots $u_n$ depend on $u_0 = S_l^0$ (remember that the $v_n$’s do not depend on the mass ratio). To zeroth order, right on the critical mass ratio, $u_n = u_n^0$ by definition. Making apparent the dependence of the function $\Lambda_l$ with $\alpha$, one has

$$\Lambda_l(iu_n; \alpha) = 0. \hfill (B2)$$
It is clear on Eq. (43) that \( \Lambda_z \) is a regular function of \( \alpha_z \), so that \( \Lambda_z(s; \alpha_z) \) around \( \alpha_z^{(l)} \) varies to first order in \( \alpha - \alpha_z^{(l)} \), and (B2) simplifies to

\[
\Lambda_i(iu_n; \alpha_e^{(l)}) = O(\alpha - \alpha_e^{(l)}). \tag{B3}
\]

We also note that \( \Lambda_i(s; \alpha_z) \) is an even function of \( s \). For \( n = 0, u_0 = S_l \) and \( v_0 = 0 \); since \( 0 \) is a double root of \( s \rightarrow \Lambda_i(s; \alpha_z^{(l)}) \), one has to expand (B3) to second order in \( u_n - u_0 \) to get the leading contribution, and \( S_0 \) varies linearly in \( \alpha - \alpha_z^{(l)} \) as expected. For \( n > 0 \), \( u_n^{\prime} \neq 0 \) and \( iu_n^{\prime} \) is a simple root of \( s \rightarrow \Lambda_i(s; \alpha_z^{(l)}) \), one has to expand (B3) to first order in \( u_n - u_n^{\prime} \) to get the leading contribution, so that

\[
u_n - u_n^{\prime} = O(\alpha - \alpha_z^{(l)}) = O(S_0^2) \quad \text{for} \quad n > 0. \tag{B4}
\]

To first order in \( S_0 \), we can thus replace the \( \nu_n \)'s in (B1) by their values \( u_n^{\prime} \) at threshold (for \( n > 0 \)).

The last step is to expand the \( \Gamma \) functions in (B1) to first order in \( S_0 \). For any real positive number \( x > 0 \), one has

\[
\frac{\Gamma(x + iS)}{\Gamma(x)} = 1 + iS\psi(x) + O(S_0^2) \tag{B5}
\]

where \( \psi(z) = \Gamma'(z)/\Gamma(z) \) is the digamma function. One has in particular \( \psi(1) = -\gamma \), where \( \gamma = 0.577215 664 \ldots \) is Euler’s constant, see e.g. relation 8.362(1) in [31]. We recall that, by definition, \( -i\nu_n \) for \( n > 0 \) and \( -i\nu_n \) for \( n \geq 0 \) are real positive. Finally, the product over \( n \) in (87) may be written as

\[
\Gamma(-iS - i\nu_n) = \frac{\Gamma(-iS - i\nu_n)\Gamma(1 - iS - i\nu_n)}{\Gamma(1 + iS - i\nu_n)}, \tag{C1}
\]

where \( \Gamma(z) \) is a regular function of \( z \). A similar rewriting can be performed on the factors involving \( -i\nu_n \), \( n > 0 \), so that, apart from an infinite product that is real positive and does not contribute to the phase of \( C_l(S) \), we identify a hard part \( D_l(S) \) that is the product of factors of the form \( \Gamma(z)\Gamma(z+1) \), with \( z = -i\nu_n - iS \) in the numerator and \( z = -i\nu_n - iS \) in the denominator. We then set

\[
\Psi(z) = \frac{\Gamma(z)\Gamma(z+1)}{2\pi e^{2\psi(2)}} \quad \text{with} \quad f(z) = z\ln z - z. \tag{C2}
\]

Here we are in the case \( Re z > 0 \) so that the branch cut of the logarithm (on the real negative axis) and the poles of \( \Gamma(z) \) are out of reach. Then

\[
D_l(S) = e^{\Sigma_i(S)} \prod_{n \in \mathbb{N}^+} \frac{\Psi(-i\nu_n - iS)}{\Psi(-i\nu_n - iS)} \tag{C3}
\]

with

\[
\Sigma_i(S) = 2 \sum_{n \in \mathbb{N}^+} \frac{|f(-i\nu_n - iS) - f(-i\nu_n - iS)|}{2\pi e^{2\psi(2)}} \tag{C4}
\]

According to the relation 8.344 in [31], \( \Psi(z) = 1 + O(1/z) \) at large \( |z| \) so that one expects that the infinite product in (C3) converges more rapidly than the original form.
(73). Furthermore, only the imaginary part of $\Sigma_l(S)$ is required, and it can be expressed as the integral

$$\text{Im} \Sigma_l(S) = -\int_0^S dS' R_l(S')$$  \hspace{1cm} (C5)

with

$$R_l(S) = \ln \left[ \frac{\Lambda_l(iS)}{\cos \nu} \right] \frac{S^2 + (l + 1)^2}{S^2 - S_l^2}. \hspace{1cm} (C6)$$

Eq. (C5) holds for $S = 0$, since $-i\omega_n$ and $-i\nu_n$ are all real positive for $n > 0$. To check that it holds at non-zero $S$, one takes the derivative of (C5) with respect to $S$, using $f'(z) = \ln z$ and $f(z)^* = f(z^*)$. One then recognizes the function $\Lambda_l(iS)$ from its Weierstrass representation (72), also using $v_0 = i(l + 1)$ and $w_0 = S_l$.

It is possible to go further and to express the phase of the infinite product in (C3) in terms of derivatives of the function $R_l(S)$. Relation 8.344 in [31] indeed gives Stirling’s representation of $\ln \Psi(z)$ as an asymptotic series in $1/z$, and one also has the $k$th derivative for $k \geq 1$:  

$$\frac{d^k}{dS^k} \ln(-i\omega_n - iS) = \frac{-i^k(k+1)!}{(-i\omega_n - iS)^k}$$  \hspace{1cm} (C7)

and similar relations obtained by taking the complex conjugate or by replacing $\omega_n$ with $\nu_n$. Finally $D_l(S) = |D_l(S)| \exp[i\varphi_l(S)]$ with

$$\varphi_l(S) = -\int_0^S dS' R_l(S') - \sum_{k \geq 1} \frac{(-1)^k B_{2k} R_l^{(2k-1)}(S)}{(2k)!},$$  \hspace{1cm} (C8)

where the $B_{2k}$ are the Bernoulli numbers and $R_l^{(2k-1)}$ stands for the $(2k-1)$th derivative of the function $R_l(S)$. The useful statement is then that

$$C_l(-S_l) e^{\varphi_l(S)}$$  \hspace{1cm} (C9)

$$\frac{\Gamma(2iS_l)\Gamma(l + 1 - iS_l)\Gamma(l + 2 - iS_l)}{\Gamma(2iS_l)\Gamma(l + 1 - iS_l)\Gamma(l + 2 - iS_l)}$$

where we used the fact that $R_l(S)$ is an even function of $S$, and thus $\varphi_l(S)$ an odd function of $S$. Minor transformations then lead to Eq. (89). In short, these results originate from the lemma: For any $x > 0$ and $S$ real,

$$\text{Im} \ln \Gamma(x-iS) + \ln \Gamma(x+1-iS) = -\int_0^S dS' \ln(x^2 + S'^2)$$

with here again the series is only asymptotic.

Appendix D: Efimovian spectrum global scale at large angular momenta

As we show here, asymptotically exact expressions of $q_{\text{global}}^{(l)}$ for a diverging angular momentum $l$ can be obtained analytically. This requires an asymptotic determination of the function $\Lambda_l(iS)$. To this end, the most convenient starting point is the expression for $\Lambda_l$ in Eq. (46). Since $\cos \nu$ tends to zero for $\alpha > \alpha_0^{(l)}$ in the large $l$ limit, we rewrite this expression using relation 9.131(2) of [31] that expresses an hypergeometric function of the variable $z$ in terms of hypergeometric functions of the variable $1 - z$. For $S$ real:

$$\Lambda_l(iS) = 1 + (-1)^l \cos \nu \left[ \frac{1}{2} \cos^2 \nu \right]$$

$$\times _2 F_1 \left( \frac{l+1+iS}{2}, \frac{l+1-iS}{2}; \frac{3}{2}; \cos^2 \nu \right)$$

$$- \frac{\Gamma(\frac{l+1+iS}{2})}{\Gamma(\frac{l+1+iS}{2})}.$$  \hspace{1cm} (D1)

For a fixed value of $S_l$, and thus considering $\alpha$ as a function of $S_l$, we expect the asymptotic expansion in the large $l$ limit:

$$\cos \nu = \frac{a_2}{l^2} + \frac{a_3}{l^3} + \ldots$$  \hspace{1cm} (D2)

Using (D1) for fixed $S_l$, the calculation of the leading coefficient of $a_l$ is straightforward, expressing each $_2 F_1$ function in terms of its defining hypergeometric series, see relation (9.100) in [31], and taking the large $l$ limit in each term of the series. For example, for any natural integer $k$:

$$\frac{(-1)^k \ldots (-1)^k}{(k + 1 - \alpha \ldots)} \frac{\cos^{2k} \nu}{(k)!} \to \frac{a_2}{l^2}.$$  \hspace{1cm} (D3)

$$\frac{(-1)^k \ldots (-1)^k}{(k + 1 - \alpha \ldots)} \frac{\cos^{2k} \nu}{(k)!} \to \frac{a_2}{l^2}.$$  \hspace{1cm} (D4)

The sum over $k$ then generates coss and sinh functions of $a_l$. Also, the Gamma functions in (D1) may be expanded using relation 8.344 in [31]. This lowest order calculation gives $\Lambda_l(iS_l) / \cos \nu = 1 - \exp(-a_1) / a_1 + O(1/l)$. Since $\Lambda_l(iS_l)$ vanishes (to all orders), one obtains $a_1 = \exp(-a_1)$ so that

$$a_1 = C$$  \hspace{1cm} (D5)

where $C$ was introduced in (77) in the Born-Oppenheimer context. This technique can be pushed in principle to any order. We calculated $a_2 = -C/2$ and $a_3$. The fact that $S_l$ does not contribute to $a_2$ (and contributes to $a_3$ in the form of a term $S_l^2$) is due to the fact that (D1) is an even function of $S$, and that it is always the ratio $S/l$ which appears in the expansion. Turning the expansion (D2) into an expansion for the mass ratio, we obtain (80), (81) and (82).

This large-$l$ expansion technique can even be extended to the case where $S_l / l = O(1)$ (which includes both the previous case of $S_l$ fixed and the new case $S_l / l$ fixed). To leading order, one finds $S_{\pm}^2 \simeq (a - \alpha_0^{(l)}) C^2 / 2$ (as in the Born-Oppenheimer approximation) and

$$\Lambda_l(iS) \simeq 1 - \frac{\exp \left[ -C \left( \frac{S^2 + \alpha^2}{S^2 + \alpha^2} \right)^{1/2} \right]}{C \left( \frac{S^2 + \alpha^2}{S^2 + \alpha^2} \right)^{1/2}}.$$  \hspace{1cm} (D6)
This shows that \( \Lambda_l(iS) \) is a function of \( S \) of width \( \propto l \) in the large \( l \) limit, so that the derivatives in (89) tends to zero in that limit, and the contribution is dominated by the integral over \( S \). Setting \( x_i \equiv s_i / l \), assumed to be bounded as we said, we then obtain an asymptotic expression for the global scale of the Efimovian spectrum:

\[
\ln(q_{\text{global}}^{(l)} R_s / 2) = \text{Im} \ln(\Gamma(1 + iS)) + \ln(1 + 2iS) - 3 \ln l \left[ \arctan x_i + \frac{1}{x_i} \int_0^{1/2} \frac{dx}{x_i} \ln F(x) + O(\frac{1}{l}) \right]
\]

with the function

\[
F(x) \equiv 1 + \frac{1}{x_i^2 - x^2} \left[ -1 + e^{-C \left( \frac{x_i}{x_i + x} \right)^{1/2}} \right] C \left( \frac{x_i + x}{x_i + x} \right)^{1/2}.
\]

In the case where \( S \) has a fixed value, for \( l \to +\infty \), one has that \( x_i \to 0 \) and one may approximate \( F \) by keeping terms up to order \( x_i^2 \) and \( x^2 \) inside the square brackets of (D8), so that \( F(x) = (1 + C)/2 + o(1) \). This gives (92). In the case where \( x_i \) fixed to a non-zero value, \( S_l \) diverges for \( l \to +\infty \) so that the Gamma functions in (D7) may be Stirling-expanded, leading to

\[
\ln(q_{\text{global}}^{(l)} R_s / 2) \bigg|_{\text{fixed } x_i} = \frac{x_i}{1 + x_i^2} \ln \frac{x_i}{1 + x_i^2} - \arctan x_i + \frac{1}{x_i} \int_0^{1/2} \frac{dx}{x_i} \ln F(x) + O(1)
\]

Furthermore, if \( x_i \gg 1 \), the first two terms in the right-hand side of (D9) tend to zero, and the integral can be shown to approach \( J + \ln(1 + C) \), where \( J \) is the integral (94). Remarkably, one then recovers for \( q_{\text{global}}^{(l)} R_s \) the same estimate as in (93), which was obtained with a different limiting procedure \( (S_l \to +\infty \text{ for } l \text{ fixed}) \). This is may be not surprising, since \( S_l / l \gg 1 \) in both cases, this is even obvious in a semi-classical picture, see discussion below Eq. (109), where the large \( \alpha \) limit is reached for \( \alpha C^2 / 2 \gg (l + 1/2)^2 \) (which implies \( S_l \gg l \)), irrespective of the fact that \( l \) is large or not.

Appendix E: Efimovian spectrum global scale at infinite mass ratio

The results (C9) or (89) are quite useful to determine \( q_{\text{global}}^{(l)} \) for \( \alpha \to +\infty \) for a fixed angular momentum \( l \). One simply needs an asymptotic expansion of \( \Lambda_l(iS) \) for \( S \) large of the order of \( S \to +\infty \), which implies that \( S \) and \( 1/\cos \nu \) both scale as \( \alpha^{1/2} \). For \( S \to +\infty \) it is apparent that the integral over \( \theta \) in Eq. (43) is dominated by the contribution of a small interval ending in \( \theta = \nu \), since here \( s = iS \). Approximating \( \sin(s \theta) / \sin(s \pi / 2) \sim \exp(S[\theta - \pi / 2]) \), we see that the small interval has a width scaling as \( 1/S \). We then Taylor-expand \( P_l(\sin \theta / \sin \nu) \) around \( \theta = \nu \) up to second order in \( \theta - \nu \), and we perform the integral over \( \theta \) extending the lower bound of the integral to \( -\infty \), which generates an expansion in powers of \( 1/S \). We can also consistently expand \( \cos \nu \) and \( \sin \nu \) up to second order in \( \pi/2 - \nu \), since \( 1/S \) and \( \pi/2 - \nu \) are of the same order. If one sets \( \epsilon = \pi/2 - \nu \), this gives

\[
\frac{\Lambda_l(iS)}{\cos \nu} = 1 - \frac{e^{-iS}}{\epsilon S} \left[ 1 + \frac{2}{\epsilon^2} - \frac{1}{2} (l + 1) \left( \frac{\epsilon}{S} + \frac{1}{\epsilon S^2} \right) \right] + O\left( \frac{1}{S^3} \right)
\]

which we used \( P_l(1) = 1 \) and \( P_l'(1) = l(l + 1)/2 \).

A first application of Eq. (E1) is an expansion of \( S_l \) in powers of \( \epsilon \). Since \( \Lambda_l(iS_l) = 0 \), one finds leading order \( S_l \epsilon = C \), where \( C \) is given by (77). Going to next order gives a correction of order \( \epsilon^2 \) to \( S_l \). Expressing \( \epsilon \) as a power series in \( \epsilon S/\cos \alpha \) gives (83).

A second application of Eq. (E1) is the derivation of the infinite-mass-ratio limit of \( q_{\text{global}}^{(l)} \). To leading order, \( \Lambda_l(iS) / \cos \nu \) is a function of \( \epsilon S \), and so is

\[
R_l(S) \simeq \ln \left( 1 - \frac{e^{-iS}}{x} \right) \left[ \ln \frac{2}{x^2 - C^2} \right] \bigg|_{x = \epsilon S}.
\]

This means that the \( (2k - 1)^{\text{th}} \) derivatives of \( R_l \) in Eq. (C8) scale as \( \epsilon^{2k - 1} \) and are negligible. The integral over \( S \) in Eq. (C8) is a leading contribution that scales as \( S_l \) as revealed by the change of variable \( x = \epsilon S \). Also the denominator in (C9) contributes with a phase factor \( \sim \exp(2iS_l \ln 2) \). Using (88) one finally obtains (94).

Appendix F: First correction to the hydrogenoid spectrum

Within the Born-Oppenheimer framework of subsection IV C, for the hydrogenoid part of the trimer spectrum, we apply the first order perturbation theory to the \( 1/r_{23}^{1/2} \) term of Eq. (103) that we call here \( \delta V \). In terms of the Bohr radius \( a_0 = h^2/(m_e e^2) = 4R_s/\alpha \), the normalized hydrogenoid wavefunction is \([64]\)

\[
\psi_{\ell}(r_{23}) = \frac{2}{(n + l) a_0} \left[ \frac{(n - 1)!}{2(n + l)(n + l + 1)!} \right]^{1/2} e^{-r_{23}/[n + l] a_0} L^{2l+1}_{n-1} \left[ \frac{2r_{23}}{(n + l) a_0} \right] Y^m_{\ell}(r_{23}).
\]

Here \( L^m_n \) is the usual Laguerre polynomial defined with the convention of [31] (and not with the one of [64]). After angular integration and the change of variable \( u = 2r_{23}/[(n + l) a_0^2} \) we obtain for the expectation value of \( \delta V \)
in that wavefunction:
\[
\langle \delta V \rangle = \frac{\hbar^2 \alpha^{1/2}}{MR^2} \left( \frac{n-1}{2} \right) \int_0^{+\infty} du \, u^2 \frac{1}{e^{-u} + 1} \left[ L_{n-1}^1(u) \right]^2. \tag{F2}
\]

To evaluate this integral, we use the generating function technique of [64]: We define
\[
I(x, y) = \int_0^{+\infty} du \, u^{\beta + \gamma} e^{-u} \varphi_{\beta}(u, x) \varphi_{\beta}(u, y), \tag{F3}
\]
where eventually we shall set \( \gamma = 1/2 \) and \( \beta = 2l + 1 \), and where the generating function of the Laguerre polynomials \( L_n^\alpha \) for fixed \( \beta \) is given for \( |z| < 1 \) by relation 8.975(1) in [31]:
\[
\varphi_{\beta}(u, z) = \sum_{n=0}^{+\infty} L_n^\beta(u) z^n = \frac{e^{-u(z/(1-z))}}{(1-z)^{\beta+1}}. \tag{F4}
\]

On one hand, since \( \varphi_{\beta} \) is the generating function,
\[
I(x, y) = \sum_{m, n=0}^{+\infty} x^m y^n \int_0^{+\infty} du \, u^{\beta + \gamma} e^{-u} L_m^\beta(u) L_n^\beta(u), \tag{F5}
\]
so we need the diagonal terms \( n = m \) in this series expansion. On the other hand, from the explicit form of \( \varphi_{\beta} \):
\[
I(x, y) = \Gamma(1 + \beta + \gamma) \frac{(1-x)(1-y)\gamma}{(1-xy)^{1+\beta+\gamma}}, \tag{F6}
\]
that it remains to expand in a series of \( x \) and \( y \) using three times \( (1-X)^\nu = \sum_{q=0}^{+\infty} X^q \Gamma(q+\nu)/\Gamma(q+1)\Gamma(-\nu) \), \( \nu \) non-integer, to obtain for a non-integer \( \gamma \):
\[
\int_0^{+\infty} du \, u^{\beta + \gamma} e^{-u} \left[ L_{n-1}^\beta(u) \right]^2 = \sum_{k=0}^{n-1} \frac{\Gamma(k+1)(-\gamma)}{\Gamma(k+1)\Gamma(-\gamma)} \Gamma(\beta + \gamma + n - k) \Gamma(n-k). \tag{F7}
\]

For \( \gamma = 1/2, \beta = 2l + 1 \), expressing the Gamma function of integers and half-integers in terms of factorials finally gives Eqs. (105,106) [65].

Physically this is clear in a real space reasoning, since it turns the scattered wave $\propto e^{i\mathbf{r}/r}$ into an exponentially decreasing function.

One uses relation 9.132(1) in [31] to map the hypergeometric function for a large and negative argument $-k^2/Q^2$ to hypergeometric functions of small and positive argument $Q^2/(Q^2+k^2)$. Second, the product of $\Gamma$ factors is simplified using the doubling formula 8.355(1) of [31] as $\Gamma(s)=2^{-s-1}\Gamma(s/2)\Gamma(1+s)/\sqrt{\pi}$, then repeatedly the relation $\Gamma(z+1)=\Gamma(z)$, and finally relation 8.332(2) of [31] in the form $\Gamma(1+s)/\sqrt{\pi} = \pi/\sin(\pi s/2)$.

The notation $\int_{-\infty-i\eta}^{\infty-i\eta} dx$ denotes integration in the complex plane from left to right on the horizontal straight line passing through the complex number $z_0$.

See e.g. C. Cohen-Tannoudji, J. Dupont-Roc, G. Grynberg, in Atomic-Photon Interaction: Basic Process and Applications (Wiley-VCH, Berlin, 1998).

Our function $C_1$ corresponds to the function $C_+\left[\frac{1}{2}\right]$, up to a Wick rotation, since a Barnes contour integral is used in [12], rather than the more common Fourier representation.

Under inspection of (43), one finds that the poles of $S \to \Lambda_1(iS)$, here $l=0$ odd, necessarily obey $\sin(s\theta)/2 = 0$, imposing that $s$ is an even integer. $s=0$ is not a pole due to the presence of the factor $\sin(s\theta)$ in the numerator of the integrand in (43). Also $0 < s < l$ cannot be a pole: According to relation 1.391(1) in [31], for $s$ even integer, $\sin(s\theta) = \cos \theta Q_{is}(\sin \theta)$ where $Q_{is}(X)$ is an odd polynomial of degree $s-1$. Injecting this form in (43), making the change of variable $u = \sin\theta/\sin\nu$, and using the fact that $P_l(u)$ and $Q_{is}(u\sin\nu)$ are odd function of $u$, one obtains the scalar product between two polynomials, $\int_{-\infty}^{\infty} du P_l(u)Q_{is}(u\sin\nu)$. As the Legendre polynomials form an orthogonal basis for this scalar product, the integral vanishes if the degree of $Q_{is}$ is less than the degree of $P_l$, that is $s-1 < l$. Numerically, we have found that the function $s \to \Lambda_1(s)$ is negative for $s = 0$ (here $\alpha > \alpha_1^{(0)}$) and is a decreasing function of $s$ over the interval $[0, l+1]$. So the imaginary roots of $S \to \Lambda_1(iS)$, that is the real roots of $\Lambda_1(s)$, are obtained by looking for changes of sign of the function $s \to \Lambda_1(s)$ with small steps (typically 100 steps) over each interval of $s$ between the two successive even integers $2n+1+l$ and $2(n+1)+l+1$, $n \geq 0$. A dichotomic search is then applied in case of sign change. The infinite products in (72,73) are approximated by keeping a maximal value of $n$, for example $n = 1000$, leading to exactly the number of factors in the numerator and in the denominator. A check is to verify that this truncated product in (72) accurately reconstructs the function $\Lambda_1(iS)/\cos \nu$ over e.g. the interval $-5 < S < 5$ for $|S| \leq 1$, that is with an error less than $10^{-5}$, otherwise the maximal value of $n$ is increased (we went up to $n = 2500$). We have also used the more rapidly convergent representation (C3,C5).

We recall that the poles of $\Gamma(z)$ are the non-positive integers $n = -1, -2, -3, \ldots$ that is $n \in \mathbb{Z}^-$, with residues $(-1)^{a-n}/n!$. As a particular consequence, the factor $\Gamma(1+iS+iS_0)$ in the denominator of Eq. (73) leads to the fact that $C_1(S)$ vanishes for $S = -S_1 + ip$, for any integer $p \geq 1$, so that $F(0)(S)$ has no pole there despite the division by the hyperbolic sine in (70). Also, according to relation 8.326(1) in [31], $\Gamma(1+iS+iS_0) = \prod_{n=k}^{\infty} \left(1 + 2\frac{1}{2^{-n}S^2}\right)$, for all $x \in \mathbb{R} \setminus \mathbb{Z}^-$ and $\forall \nu \in \mathbb{R}$, the function $\Gamma(z)$ has no root in the complex plane.

L. Proukpenko, Phys. Rev. A 82, 043633 (2010).

The same work can be gone for $x \to +\infty$. Closing the integration contour by a half-circle at infinity in the upper half of the complex plane, one finds that the leading contribution to $F(0)(x)$ originates from the pole $z = v_0 + i(\ell + 2\nu)$ (see Fig.1) so that $D(k)$ vanishes as $1/k^{1+\epsilon}$ for $k \to +\infty$.

One splits the functions $C_1$ and $\Lambda_1$ as $C_1(S) = C_{\text{other}}(S) + C_{\text{other}}^\text{\Lambda_1}(S)$ and $\Lambda_1(iS) = \cos \nu(S^2 - S_0^2) \times C_{\text{other}}^\text{\Lambda_1}(iS)$. Then from $\Gamma(z) = iz\Gamma(z) \times \Lambda_1^{\text{other}}(iS)$, the property $[\Gamma(z)]^* = \Gamma(z^*)$ and the fact that $\nu_0$ and $\nu_0$ are purely imaginary for $n > 0$ lead to $[C_{\text{other}}^\text{\Lambda_1}(z)]^* = C_{\text{other}}^\text{\Lambda_1}(-z^*)$ in the complex plane. As a consequence, $[C_{\text{other}}^\text{\Lambda_1}(S)]^* = C_{\text{other}}^\text{\Lambda_1}(-S)$.

Expressing $C_{\text{other}}^\text{\Lambda_1}$ in that equation in terms of the original function $C_1$ (this requires taking a limit $S \to S_1$), together with the relation $[\Gamma(2iS)]^2 = \pi/2|S| \sin[2\pi|S|]$, cf. relation 8.332(1) of [31], gives (74). Similarly one has $F(0)(S)^* = F(0)(-S^*)$ and $F(0)(k)$ is purely imaginary (for real $k$).

This can also be obtained from the fact that $A(x)$ in (48) scales as $x^{-1+\epsilon}$ for $x \to 0$, and that the correctly nor-
nalized extra-particle wavefunction (99) involves a factor $\kappa^{1/2} \propto 1/r_{23}$. 

[45] O.I. Kartavtsev, A.V. Malykh, Zh. Eksp. Teor. Phys. 86, 713 (2007).

[46] To efficiently obtain (82) we took $1/L = 1/(l + 1/2)$ as the small parameter, so that \( \cos \nu = (C/L)(1 + e^{L^2}/4 + O(1/L^2)) \) at the critical mass ratio. To calculate sums of the type $S = \sum_{n \geq 0} P(n)k^{2n}/(2k)!!$, where $P(k)$ is a polynomial, we expanded $P(k) = \sum_n c_n Q_n(k)$ on the basis of polynomials $Q_n(k) = (2k)(2k-1)\ldots(2k-n+1)$, $Q_n(0) = 0$ iff $0 \leq p < n$, $p$ integer, so that the coefficients $c_n$ are straightforward to express in terms of the $P(p)/2^p$'s. Then $S = \sum_n c_n C^n \cos C + \sum_n \text{odd} c_n C^n \sinh C$. For $S = \sum_{k \geq 0} (P(k)k^{2k+1}/(2k+1)!)$, we defined $Q_n(k) = (2k+1)\ldots(2k+1-n+1)$, with $Q_n(0) = 0$ iff $0 \leq p < n$, $p$ integer, so that $S = \sum_n \text{even} c_n C^n \sin C + \sum_n \text{odd} c_n C^n \cos C$. 

[47] The proportionality of Eqs. (55, 75) implies that $C_1 k^{3i} + c.c. = \lambda (C_2 k^{3i} + c.c.)$, where $C_1$ (respectively $C_2$) is the coefficient of $k^{3i}$ in the expression between curly brackets in (55) (respectively in (75)) and $\lambda$ is the proportionality factor. Since the functions $k \rightarrow k^{3i}$ are linearly independent, this is satisfied iff $C_1 = \lambda C_2$ and $C_1^* = \lambda C_2^*$, that is $C_1/C_2$ = $C_2/C_1$. This last equation may be naturally written is the form $X^{3i} = 1$, which implies that the quantity $X$ is an integer power of $e^{-\pi/2}$. 

[48] V. Efimov, Phys. Rev. C 47, 1876 (1993); L. Pricoupenko, Phys. Rev. A 73, 012701 (2006).

[49] $x \rightarrow e^{-\nu}/x$ indeed decreases from $\infty$ to $0$ for $x \in \mathbb{R}^+$. 

[50] For the zero range limit $b \rightarrow 0$ taken in Section II to be physically valid, $q_0^0$ has to remain smaller than unity. 

[51] Note that the difference between the extra-particle mass $M$ and the reduced mass $\mu$ does not enter at this order yet. 

[52] A.B. Migdal, in Qualitative methods in Quantum Theory (W.A. Benjamin, Massachusetts, 1977).

[53] Starting from Eq. (95), one sets $\psi(r) = Y_{l_0}^{m_0}(r)f(r)/r^{1/2}$ so that $f(r)$ obeys a 2D Schrödinger's equation. Then one sets $f(r) = F(x)$ with $x = \ln(r/R_0)$, so that $f''(x) + f'(x)/r = F''(x)/r^2$. After multiplication by $r^2$ one obtains $-F''(x) + W(x)F(x) = 0$, to which one applies the usual WKB approximation. Here $W(x) = (l + 1/2)^2 + R_0^2x^2[Q^2 - \alpha_0^2(R_0^2e^{2y})^2]$, where the $r$ dependence of $\alpha(r)$ is included in the writing. The WKB approximation requires that $\int_{-\infty}^{\infty} dW(x)/W(x)^{-1/2} \ll 1$ away from the turning points. For $(QR_0)^2x^2 < |s_{SO}|^2$, where $s_{SO}$ is given by Eq. (78), this imposes $|s_{SO}| \gg 1$, that is one has to be far from the Efimovian threshold. 

[54] Taking the large $x_1$ limit in Eq. (D9) up to order $1/|x_1|$ included, we obtain exactly Eq. (110), knowing that $S_1$ and $|s_{SO}|$ may be identified at this order. This at least shows that the coefficient of the $1/|s_{SO}|$ term in Eq. (110) is exact in the large $l$ limit. Furthermore, one can extend the estimates (E1) and (E2) to the interval $0 < S \ll 1/e$ by approximating $\Lambda_0(iS)$ by the limit $\Lambda_0^{\text{app}}(iS)$ of Eq. (43) for $\nu \rightarrow \pi/2$. Since $-\text{SA}_{\nu}^{\text{app}}(iS) = \text{coth}(\pi S/2) \prod_{n=0}^{l-1/2} \frac{s_{\nu}^2+(2n+1)^2}{s_{\nu}^2+(2n+2)^2}, \int_{-\infty}^{\infty} dS \ln[-\text{SA}_{\nu}^{\text{app}}(iS)] = -(l + 1/2)^2/\pi^2$, and one finds from Eq. (89) that Eq. (110) is exact for all $l$.

[59] From the expression of $q_0^0(k)$, it is apparent that the actual condition is $q_0 R_{\text{max}} \cos \nu \gg 1$. 

[60] To evaluate in a numerically stable way the integral over $u$ in (116), we used that fact that $\int_{-\infty}^{\infty} a(I)P(u)/(v-u) = Q_1(v)$ where $v > 1$ and $Q_1(v)$ is a Legendre function of the second kind, see relation 7.224 in [31]. We then used an open Fortran library to calculate that function, see e.g. mlqnb.980 in specfun, and also a home-made routine using a high order 1/$v$ expansion, with similar results. Furthermore, for $x \gg 1$ and $X > 1$, one has $v \approx \cos(x-X)/\sin(x)$, so that one faces the function $y = Q_1(\cos(y)/\sin(y))$, which behaves for $y \ll 1$ and for $|\nu - \pi/2| < 1\ll 1$ as $\ln[1/(y^2 + \cos^2 y)]$. We thus checked that our discretization step for $x$ and $X$ verifies $dx = d(\ln(k)) < \cos \nu$. Note that, from the usual definition $P(u) = (2^{-l}/l!) d^l_0(u^2 - 1)^l$, one can show (by integration by part) that $Q_1(v) > 0$ for $v > 1$, for $I$ of any parity. The kernel in (116) has thus positive matrix elements for $I$ even, and negative for $I$ odd.

[61] We estimate here the issue of magnetic field stabilization for a narrow Feshbach resonance such as the one of $^6$Li-$^7$K. The 1/$a = 0$ assumption imposes the filtering $q_{R_1} > 10R_1/a$ on our results, as we said. The finite experimental value of the scattering length is, according to Eq. (12), $\approx a_{\text{eff}}\Delta B/\delta B$ where $\delta B$ is the experimental control on the magnetic field. For the modest choice $10R_1/a = 10^{-1}$, which amounts to restricting our Fig.6a to $q_{R_1} > 10^{-1}$, and taking typical $^6$Li-$^7$K Feshbach resonance parameters, $R_1 \approx 100\muJ, \Delta B \approx 0.1mT, a_{\text{eff}} \approx 3nm$ [8–10], we reach the condition $4B \approx 30kHz - 0.3mG$, which requires magnetic shielding but remains accessible [66].
