ABSTRACT

It is known that controlling the speed of a three phase Induction Motor (IM) under different operating conditions is an important task and this can be accomplished through the process of controlling the applied voltage on its stator circuit. Conventional Proportional- Integral- Differential (PID) controller takes long time in selecting the error signal gain values. In this paper a hybrid Fuzzy Logic Controller (FLC) with Genetic Algorithm (GA) is proposed to reduce the selected time for the optimized error signal gain values and as a result enhances the controller and system performance. The proposed controller FL with GA is designed, modeled and simulated using MATLAB/ software under different load torque motor operating condition. The simulation result shows that the closed loop system performance efficiency under the controller has a maximum value of 95.92%. In terms of efficiency and at reference speed signal of 146.53 rad/sec, this system performance shows an enhancement of 0.67%, 0.49% and 0.05% with respect to the closed loop system efficiency performance of the PID, FL, and PID with GA controllers respectively. Also the simulation result of the well designed and efficient GA in speeding up the process of selecting the gain values, makes the system to have an efficiency improvement of 14.42% with respect to the open loop system performance.

Fuzzy logic controller
Genetic algorithm
Induction motor
PID controller

1. INTRODUCTION

Three-phase induction motors have a wide industrial applications due to their ability for working under different environmental operation conditions. Also the attractive features (such as high reliability, wide range of speed variation, low maintenance requirements and low cost) of these motors make them the preferred choice for customers. Different methods have been proposed to control motor speed according to its application importance. One of these simple and common method is to change the number of stator poles, so that speed value can be doubled, (in an increasing or decreasing matter). For the applications that require a wide range of speed factor variation, the applied voltage and frequency can be considered an efficient method. Different types of classical controller had been recycled to adjust the IM speed. PID controller is considered one of the most convention technique that had been used to cover the speed of the motors due to its simple structure as well as the easy understandable action of its parameters (Proportional, integral and derivative).

The field-oriented controller (FOC) is a common method operated to control the speed of the induction motor, where the motor behaves like a dc motor. A classical PI controller (that is fixed in the forward path for tracking the motor speed variation and gain values selection) is time consuming. To overcome this problem and in order to obtain the best gain value, the PI controlled genetic algorithm has
been used to generate the parameters of the PI controller, as a result the time required to select the controller gain values is reduced [1]. The motor speed can also be controlled by varying the stator voltage where the develop torque is directly proportional to the square of the applied voltage. The voltage source inverter (VSI) normally used to vary the supplied voltage of the induction motor, whereas FLC had been introduced to enhance the system performance based on direct torque and flux control methods [2].

The main problem for controlling the speed of IM is nonlinearity behavior of flux due to core saturation at high magnetization current specially at starting or during heavy motor loading. A direct torque control method (DTC) with FLC has been considered to improve the performance of motor operation. A dual FLC are used to get accurate performance for the develop torque and motor speed. A classical PI controller had been used to reduce the generated ripples with the develop torque and motor speed because of inverter harmonics [3]. A quantum lightning search algorithm (QLSA) with particle swarm optimization (PSO) had been studied in conjunction with backtracking search algorithm (BSA) to obtain the optimal values for the conventional PI and PID controllers. The optimized gain values are used to improve the induction motor speed control performance [4]. Among the different methods which are used to control the speed of the induction motor, the v/f method was considered the preferred one over others because of its ability to vary the motor speed over wide range compared with other types. A sinusoidal Pulse-Width Modulation (PWM) technique was used to feed the VSI. Due to their simple structure, the PI and FL controllers were used to investigate the operation performance of the IM in open loop system and closed loop system [5].

The PID controller had been used to reduce the effect of the disturbance associated with conventional controller. Also the speed of a three phase IM was controlled through a vector control based on FL technique. The obtained results show the fuzzy logic controller ability to overcome the problems which occur with the classical PID controller [6]. Neural network controller (NNC) have a wide range of applications in the field of electric machine’s speed control. The operation of the IM is studied under the effect of external disturbance, the model explains the stability when the feed-forward neuro controller is used. Then a neuro-fuzzy controller is introduced to implement a vector controlled for the three phase IM. The results show the flexibility of the neuro-fuzzy controller in comparison with others [7].

FLC had been used to control the operation of a 3-Φ IM, through the selection of the duty cycle for the PWM. The output performance of the IM with the FL controller has been investigated under the disturbance of the applied external load torque [8]. Fuzzy logic controller also used with a sudden changes in load or speed conditions. Although scaler and vector control methods have been used to adjust the speed of machine, vector control method (which consist of direct and indirect field-oriented technique) has been widely used by many authors as an advanced method to obtain an accurate control for the speed of the motor and minimize the IM performance error [9]. An experimental real time control is considered in the process of modeling, simulating and implementing the structure of an IM system [10].

Due to its good quality output voltage and customized fast switching five stage NPC inverter is used by [11] to drive the induction motor using field orientation control strategy. This strategy is used to overcome the drawbacks (fast switching losses and high level harmonic with distorted output voltage) of the controlled two level inverter. The authors in [12] have suggest anew strategy based on the artificial neural network with direct torque control to reduce the effect of the problem (high current, flux and torque ripple as well as flux control at very low speed) which present in the conventional direct torque control. In reference [13] a predicative model reference adaptive system (PMRAs) rotor speed observer is proposed to produce the motor position more accurate and minimizes the tuning error of speed signal. The result of this observer is confirmed by simulation and showed a good dynamic performance in terms of rotor speed and position at low and zero speeds.

Different strategies for speed control of three phase IM have been used depending on the required application. First a classical methods are used to control the rotation of the motor for application that require small degree of accurate rotation. Voltage and frequency control (V/f) is considered the most common used method in this field to adjust the dynamic performance of the motor and also the best way to obtain a uniform flux during the operation. For industrial application where the change of speed and torque is an important factor, it is very necessary to have an efficient and accurate controller. Now days inelegant techniques like fuzzy, neural and genetic methodology are used to obtain a better controller performance to control the electric machines. In this paper the speed of the IM is controlled by varying the stator voltage. A a 3-phase voltage source inverter (VSI) with (SPWM) is used to control the motor supply voltage by controlling the applied firing angle to the power electronic devices. The width of triggering pulses on the drive circuit are tuned based on the difference between the reference and output signals. The error signal has been fed to the inputs of the designed PID and FL controllers with GA.
2. MODELING OF THREE-PHASE INDUCTION MOTOR

Two types (electrical and mechanical) of equations are involved in the modeling processes of the three phase IM. The electrical (1)-(6) represent the modeling of relation between the electrical stator parameters, rotor parameters and the mutual effect between them, whereas (7) clarify the modeling of the developed electrical torque relationship.

\[
\begin{align*}
V_s &= i_s r_s + \frac{d\psi_s}{dt} + j\omega_s \psi_s \\
V_r &= i_r r_r + \frac{d\psi_r}{dt} + j(w_s - w_r)\psi_r \\
\psi_s &= L_s i_s + L_m i_r \\
\psi_r &= L_r i_r + L_m i_s \\
L_s &= L_{ls} + L_m \\
L_r &= L_{lr} + L_m \\
T_n &= T_1 + \frac{2}{P} \frac{d\omega}{dt}
\end{align*}
\]

where:
\(V_s, i_s, r_s\) represent the stator voltage, current and resistance respectively. \(V_r, i_r, r_r\) represent the rotor voltage, current and resistance respectively. \(L_s, L_{ls}, L_{lr}, L_m\) are the stator, rotor and mutual inductances respectively. \(J\) is the moment of inertia of the rotor and load, \(P\) is the number of pole pairs, \(T_L\) is the load torque. The parameters of the IM that have been simulated in current paper are given in Table 1.

| parameters   | values | parameters   | values |
|--------------|--------|--------------|--------|
| \(P_f\) [KW] | 4.028  | \(L_r\) [H]  | 0.00584|
| \(V\) [V]   | 220    | \(L_{ls}\) [H] | 0.1722 |
| \(f\) [Hz]  | 50     | \(R_s\) [Ω]  | 1.405  |
| \(L_{lr}\) [H] | 0.00584 | \(R_r\) [Ω]  | 1.395  |
| \(\cos\phi_n\) | 0.8    | \(J\) [kg.m²] | 0.065  |
| \(F_c\) [N.m.s/rd] | 0.00298 | \(P\)         | 4      |

3. SPWM METHOD

PWM methods have usually used in voltage source and current source inverter to fed AC motor drives. In this work, a sinusoidal pulse width modulation (SPWM) technique has been selected to generate the switching signals. This method is used in many types of industrial applications. While the control variety for its modulation index is moderately fine, SPWM is a modest method and has well transient response. A high-frequency triangle carrier signal is compared with a three phase sinusoidal signal from supply frequencies as exposed in Figure 1. The power plans in separately phase are exchanged on at the connection points of the sine wave and triangle wave. The modulation index which is given by the ratio of the carrier amplitude to sinusoidal signal amplitude is used to decide the value of the output voltage.

\[
M_i = \frac{A_c}{A_r}
\]

Where \(A_c\) is the carrier amplitude and \(A_r\) the sinusoidal signal amplitude.
4. **THE PID CONTROLLER**

A conventional PID controller plays an important role in various control processes. It is mainly used to reduce or eliminate the steady-state error of the system response and as a result it improves the dynamic behavior of the system. So the proportional part of the controller enhances the transient step response of the system (rising time, steady state error), the derivative part of the controller increases a limited zero to the open-loop plant transfer function and improves the transient response (overshoot, rising time, settling time and peak time). While the integral part adds a pole at the origin, which adds one to the system type and thus the steady-state error for a step input function will be reduced to zero. The general formula for the PID controller is defined as:

\[ \text{PID} = K_P + K_I/S + K_D S \]

where the control parameters \( K_P, K_I \) and \( K_D \) are the proportional factor, the integral factor and the derivative factor correspondingly. The block diagram of PID controller as shown in Figure 2.

![Figure 2. The block diagram of PID controller](image)

Different methods have been used to calculate the controller parameters like trial and error method, Ziegler-Nichols method and another modern algorithms [1], [14].

5. **DESIGN OF FUZZY LOGIC CONTROLLER (FLC)**

In this paper the fuzzy logic controller (FLC) is carefully designed with two inputs and one output. The error \( e(t) \) and change of error \( \Delta e(t) \) are considered as input signal to this FLC. The output signal has been feed to the 3-phase VSI to control the applied voltage to the IM terminals. The linguistic variables \( (N,NB,NS,Z,P,PS,PB) \) and the fuzzy rules are defined and summarized in Table 2. The triangular membership functions are chosen to represent the input (error and change in error signals) for this fuzzy logic controller. An appropriate scale ranges (-100 to 100 for \( e(t) \)) and (-50 to 50 for \( \Delta e(t) \)) are selected.
Table 2. Fuzzy logic controller rule base

| $\Delta e$ | NB | N  | NS | ZE | PS | P  | PB |
|------------|----|----|----|----|----|----|----|
| NB         | NB | NB | NB | NB | N  | NS | ZE |
| N          | NB | NB | NB | N  | NS | ZE | PS |
| NS         | NB | NB | N  | NS | ZE | PS | P  |
| ZE         | NB | N  | NS | ZE | PS | P  | PB |
| PS         | N  | NS | ZE | PS | P  | PB | PB |
| P          | NS | ZE | PS | P  | PB | PB | PB |
| PB         | ZE | PS | P  | PB | PB | PB | PB |

$Z =$zero, $N =$negative, $NB =$negative big, $NS =$negative small

$P =$positive, $PB =$positive big, $PS =$positive small

6. GENETIC ALGORITHM (GA)

Genetic algorithm has a wide application in control process because of its ability to work as an optimization tool instead of the conventional control type. GA technique is considered as an adaptive method for searching the solution of difficult problems where it can be combined with other intelligent methods. It consists of many solution steps like, Initial population, Crossover, Selection, Mutation, Fitness function and Stopping criteria [1], [15]. Due to the drawback (long time to select the gain values) of conventional methods, GA has been effectively used to determine the controller parameters value. GA is used in the current work to select the optimized (error and change of error) gain values of the fuzzy logic controller. Table 3 shows the selected value of the parameters that are used in this GA.

| Parameters          | Values |
|---------------------|--------|
| Number of string (population) | 40     |
| Number of generations | 50     |
| Probability of crossover ($P_c$) | 1.0    |
| Probability of mutation ($P_m$) | 0.01   |

7. HYBRID CONTROLLER DESIGN

The classical try and error method (which is applied to select the parameter values of the PID controller and FL controller gains) requires a long computation time and cannot produce the optimal results. The genetic optimization algorithm can be designed and programed to get an optimal controller parameters. This algorithm can be used to search the best PID and FL controller parameters gain value, which leads to a better performance control system and eliminate the long computation time for gains determination. The optimization genetic algorithm is programed using MATLAB software package. The steps of implementing the hybrid algorithm of PID with FL controller are explained by the flowchart shown in Figure 3.
8. SIMULATION RESULTS AND ANALYSIS OF THE PROPOSED HYBRID CONTROL SYSTEM

Based on MATLAB/Simulink software a 3-phase IM driven by VSI has been modeled and simulated as shown in Figure 4. Two types PID and FL of classical controller have been used in the feedback loop to adjust the dynamic performance parameters (develop torque and rotor speed) of the induction motor. A genetic algorithm has been introduced to speed up the gain selection processes and improve the behavior of the conventional PID controller as well as adjusting the gains at FL controller input. The induction motor has been simulated under no load and then different load torque values have been applied on the shaft of the tested motor.

![Figure 4. Three phase IM fed by VSI system block diagram](image)

The open loop simulation results of the developed torque, stator and rotor currents and motor speed are shown in Figures 5-6 for (TL=0, 5 and 15 Nm) at the time (0,1 and 2 second) respectively, these show the dynamic characteristic of the tested motor under this loading criteria. Under closed loop, the different between the actual motor speed signal and reference speed signal is fed to the input of the classical PID controller. The error signal has been processed by the controller and used as a control signal to decide the amplitude and intervals of the PWM output. The reference speed are selected to be equal to 104.66, 125.56 and 146.53 rad/sec. Figures 7-8 show, the motor speed, stator current ,rotor current and electromagnetic torque under the effect of the conventional controller. For the same above loading conditions and at the same time intervals, Figures 9-10 show the simulation results improvement in the performance of the IM under the effect of the proposed intelligent FL controller. Finally in order to reduce the computation time of the controller gains and to get the optimal gain values of the classical PID and FLC a genetic algorithm has been used. Figures 11-12 and Figures 13-14 clarify the improvement in system performance due to the application of GA with the controllers PID and FL respectively.

Table 5. A brief comparison between theoretical and simulated torque at different operation conditions for open loop system

| Time (s) | Steady state speed (rad/s) | Applied torque [N.m] | Theoretical developed torque [N.m] | Simulated developed torque [N.m] |
|----------|----------------------------|----------------------|-----------------------------------|----------------------------------|
| 0.8      | 157                        | 0                    | 0                                 | 0.147                            |
| 1.5      | 152                        | 5                    | 5                                 | 5.113                            |
| 2.5      | 136                        | 15                   | 15                                | 15.120                           |

Figure 13. Speed response with hybrid FL/GA controller

Figure 14. Stator, Rotor Currents and electromagnetic torque with hybrid FL/GA Controller and reference speed 146.53 rad/sec
Table 6. A brief comparison between theoretical and simulated torque at different operation conditions for with FL/GA

| Time (s) | Steady state speed (rad/s) | Applied torque [N.m] | Theoretical developed torque [N.m] | Simulated developed torque [N.m] |
|---------|---------------------------|----------------------|-----------------------------------|---------------------------------|
| 0.8     | 157                       | 0                    | 0.183                             | 15.132                          |
| 1.5     | 152                       | 5                    | 5.126                             |                                 |
| 2.5     | 136                       | 15                   | 15.132                            |                                 |

Also from the Table 5, one can conclude that the performance of the open loop system has high values of steady state time, state steady error, delay time and rising time values. The closed loop system with FL or PID controller has a better performance compared with open loop system. Also in comparison with the other controllers the obtained results show that the hybrid FL with GA controller has the best improvement in the system performance.

9. CONCLUSION

Three-phase inverter have been used to convert DC voltage to an AC voltage and used to drive a 3-phase IM. The FL and PID controllers are designed and their gain values computed using try and error method while the genetic algorithm is introduced to compute the classical PID and the proposed FL controllers gain values, the output of FL controller is used to decide the value of the PWM modulation index and control the operation of the three phase inverter gates as drive for the IM to improve its performance. Different controller (FL, PID, PID/GA and the proposed FL/GA) techniques are used to control the system output speed response and enhance its performance. These techniques for controllers are modeled and the simulated under different operating conditions for open loop and closed loop systems. The simulation results show that the proposed FL/GA has the best efficiency (95.92%) performance with an improvement of 14.42% with respect to the open loop system performance. Also the proposed controller shows an enhance efficiency gains of 0.67%, 0.49% and 0.05% with respect to the PID FL and PID/GA respectively. Results show clearly improvement in the operation of the induction motor with a hybrid FL/GA algorithm control technique. The simulation results show goal consistory with the theoretical results according to the mathematical formula in (7) which describe behavior of the develop torque with the different applied torque of different times.
