ABSTRACT
One of the effective mechanisms of neutrino energy losses in red giants, presupernovae and in the cores of white dwarfs is the emission of neutrino-antineutrino pairs in the process of plasmon decay. In this paper, we numerically calculate the emissivity due to plasmon decay in a wide range of temperatures ($10^7 - 10^{11}$) K and densities ($2 \times 10^2 - 10^{14}$) g cm$^{-3}$. Numerical results are approximated by convenient analytical expressions. We also calculate and approximate by analytical expressions the neutrino luminosity of white dwarfs due to plasmon decay, as a function of their mass and internal temperature. This neutrino luminosity depends on the chemical composition of white dwarfs only through the parameter $\mu_e$ (the net number of baryons per electron) and is the dominant neutrino luminosity in all white dwarfs at the neutrino cooling stage.

Key words: stars: neutrino processes – red giants – presupernova – white dwarfs.

1 INTRODUCTION
It is well known that neutrino emission plays an important role in the evolution of red giants, presupernovae, white dwarfs, and neutron stars. Neutrinos appear in a number of reactions in dense stellar matter (see, e.g., Yakovlev et al. 2001) and freely escape from the star, producing a powerful mechanism of their cooling. One of the effective neutrino generation mechanisms is the plasmon decay.
In contrast to ordinary photons in vacuum, plasmons, which are quanta of electromagnetic field in a plasma, can be not only transverse (in this case two polarization vectors of plasmon are perpendicular to wave vector), but longitudinal as well. The longitudinal plasmons appear in the theory as a result of quantization of the well known Langmuir plasma waves.

Plasmon can decay into a neutrino-antineutrino pair, $\gamma \rightarrow \nu + \overline{\nu}$. The appropriate neutrino emissivity was analyzed in a series of papers since 1963, when Adams, Ruderman, and Woo had suggested this mechanism of energy losses in dense stellar matter for the first time. An account of these papers and references can be found in the review by Yakovlev et al. (2001) as well as in a recent paper by Odrzywołek (2007). Here we discuss in more detail only three papers which summarize and extend the results of previous works.

Itoh et al. (1992) calculated the emissivity due to plasmon decay as a function of temperature and density and presented a table of numerical values and an approximate fit formula. Unfortunately, this approximate formula does not reproduce analytical asymptotes for the emissivity and thus can be applied only in a restricted region of temperatures and densities (near the maximum value of the emissivity). In addition, when calculating the emissivity, Itoh et al. (1992) used approximate expressions for the dielectric functions of electron gas and for plasmon dispersion relations which can be justified only at low enough temperatures (in a strongly degenerate electron gas).

On the contrary, Braaten & Segel (1993) started with the most general expressions for the neutrino emissivity due to plasmon decay. They did not make any assumptions concerning degeneracy of the electron gas at calculating the dielectric functions and plasmon dispersion relations. To simplify their analysis, Braaten & Segel (1993) suggested an elegant scheme to calculate approximately the dielectric functions, dispersion relations, and the neutrino emissivity. However, these authors did not present any tables with their numerical results or any approximate formula for the emissivity. Therefore, it is difficult to use their results in applications.

Using the approximate method of Braaten & Segel, Haft et al. (1994) calculated the emissivity due to plasmon decay and fitted it by an analytical formula. This formula accurately describes the emissivity in a range of temperatures and densities where the plasmon decay is the most important neutrino emission mechanism. However, the fitting expression of Haft et al. (1994) does not satisfy the analytical asymptotes for the emissivity (they are presented in Section 2).
The neutrino emission due to plasmon decay and neutrino luminosity of white dwarfs

In this paper we would like to fill in the gaps in the literature devoted to the subject. We will (i) numerically calculate the neutrino emissivity due to plasmon decay making no assumptions concerning degeneracy or relativity of the electron gas; (ii) employ the approximate scheme of Braaten & Segel and find a fitting expression for the emissivity which reproduces the correct asymptotes. Thus, our main goal is to facilitate the use of the data on the neutrino emission due to plasmon decay.

The paper is organized as follows. In Section 2 we present general equations describing the neutrino energy loss rate owing to plasmon decay. In Section 3 we give the fit expression for the plasma frequency which is a key parameter because the asymptotes of the emissivity depend on it. In Section 4 we present the fit expressions for the emissivity. In Section 5 we apply the results of the preceding sections and find an analytical formula describing the neutrino luminosity of white dwarfs as a function of their mass and internal temperature. We summarize in Section 6. In Appendix A we present expressions for the dielectric functions of the electron-positron plasma. Finally, in Appendix B we describe a table of our numerical results.

2 GENERAL EQUATIONS

The neutrino emissivity due to plasmon decay can be presented as a sum of three components: the longitudinal component \( Q_L \) (due to decay of longitudinal plasmons); the transverse component \( Q_T \) (the decay of transverse plasmons governed by the vector part of the weak interaction Hamiltonian); and the axial component \( Q_A \) (the decay of transverse plasmons governed by the axial part of the weak interaction Hamiltonian). The component \( Q_A \) is small and can be neglected (see, e.g., Kohyama et al. 1994).

The emissivities \( Q_T \) and \( Q_L \) (per unit volume) are given in the form of integrals (see, e.g., Braaten 1991, Braaten & Segel 1993)

\[
Q_T = 2 Q_0 \frac{\hbar^9}{m_e^9 c^{15}} \int_0^\infty dk k^2 Z_t(k) \left( \omega_t^2 - k^2 c^2 \right)^3 n_B(\omega_t),
\]

\[
Q_L = Q_0 \frac{\hbar^9}{m_e^9 c^{15}} \int_0^{k_{\text{max}}} dk k^2 Z_l(k) \left( \omega_l^2 - k^2 c^2 \right)^3 n_B(\omega_l).
\]

Here, the integration is carried over the plasmon wave number \( k \). In equations (1) and (2) \( Q_0 = \left[ (m_e c)^9 / h^{10} \right] \left[ G_F^2 / (96\pi^4 \alpha) \right] \left( \sum_{\nu} C_V^2 \right) \approx 1.3858 \times 10^{21} \text{ erg s}^{-1} \text{ cm}^{-3} \); \( G_F = 1.436 \times 10^{-49} \text{ erg cm}^3 \) is the Fermi weak coupling constant; \( \alpha = e^2 / (hc) \approx 1/137 \) is the fine structure constant; \( e \) and \( m_e \) are the electron charge and mass, respectively; \( \hbar \) is the Planck con-
stant; \( c \) is the speed of light; \( \sum_{\nu} C_{\nu}^2 \approx 0.9248 \) is the sum of squared normalized vector constants \( C_{\nu} \) over all neutrino flavors. Furthermore, \( \omega_t(k) \) and \( \omega_l(k) \) are, respectively, the frequencies of transverse and longitudinal plasmons, which depend on the wave number \( k \); \( Z_t(k)^{-1} \equiv \partial(\omega_t^2 \epsilon_t)/\partial(\omega_t^2) \); \( Z_l(k)^{-1} \equiv (\omega_l^2 - k^2 c^2) \partial \epsilon_l/\partial(\omega_l^2) \), where \( \epsilon_t \) and \( \epsilon_l \) are the transverse and longitudinal dielectric functions of the electron-positron plasma, respectively. Finally, \( n_B(\omega_{t,l}) = 1/\{\exp[\hbar \omega_{t,l}/(k_B T)] - 1\} \) is the Bose-Einstein distribution function for transverse or longitudinal plasmons; \( T \) is the temperature; \( k_B \) is the Boltzmann constant; \( k_{\text{max}} \) is the maximum wave number at which the decay of longitudinal plasmon is still kinematically allowed by energy and momentum conservation laws.

In the astrophysical literature the emissivity is presented as a function of temperature \( T \) and the effective mass density \( \tilde{\rho} \), given by

\[
\tilde{\rho} \equiv \rho/\mu_e, \tag{3}
\]

where \( \rho \) is the actual mass density; \( \mu_e = \sum_i A_i n_i/(\sum_i Z_i n_i) \) is the net number of baryons per electron; \( Z_i \) and \( A_i \) are, respectively, the charge and mass numbers of atomic nucleus species \( i \); \( n_i \) is the number density of these species. Notice, that at densities higher than the neutron drip density \( \rho_d \approx 4 \times 10^{11} \) g cm\(^{-3} \), free neutrons must be taken into account in the sum over \( i \), in addition to atomic nuclei, when calculating \( \mu_e \).

It is straightforward to verify that \( \tilde{\rho} \) can be rewritten as

\[
\tilde{\rho} \approx (n_e - n_{e^+}) m_u. \tag{4}
\]

Here, \( n_e \) and \( n_{e^+} \) are the number densities of electrons and positrons; \( m_u \) is the atomic mass unit.

The dependence of the emissivity \( Q = Q_t + Q_l \) on \( \tilde{\rho} \) for temperatures \( T = 10^7, 10^8, 10^9 \), and \( 10^{10} \) K is presented in Fig. 1. As seen from the figure, at fixed \( \tilde{\rho} \) the emissivity increases with the growth of \( T \). If we fix \( T \), the dependence \( Q(\tilde{\rho}) \) has a maximum. In the vicinity of the maximum the plasma frequency of the electron-positron plasma \( \omega_p \) is of the order of temperature, \( \hbar \omega_p \sim k_B T \) (see Section 5 for details). At high temperatures and low densities the emissivity ceases to depend on \( \tilde{\rho} \) (see equations 6, 10, and 11 below). In the figure this situation is illustrated by the upper curve, which is plotted for \( T = 10^{10} \) K. One sees that at \( \tilde{\rho} < 10^8 \) g cm\(^{-3} \) the curve tends to be horizontal.

As follows from equations 11 and 2, for calculation of \( Q_t \) and \( Q_l \) one needs to know the dispersion relations for transverse and longitudinal plasmons, \( \omega_t(k) \) and \( \omega_l(k) \), as well as the dielectric functions \( \epsilon_t(\omega, k) \) and \( \epsilon_l(\omega, k) \). We calculated the dielectric functions \( \epsilon_t(\omega, k) \) and \( \epsilon_l(\omega, k) \).
The neutrino emission due to plasmon decay and neutrino luminosity of white dwarfs

Figure 1. The emissivity $Q = Q_t + Q_l$ versus $\rho$ for $T = 10^7, 10^8, 10^9,$ and $10^{10}$ K.

and $\epsilon_i(\omega, k)$ for a wide range of densities and temperatures in the random phase approximation and numerically obtained the dispersion relations and the plasma frequency $\omega_p$. The equations we used to compute the dielectric functions of the electron-positron plasma are given in Appendix A. These results were applied to calculate the integrals (1) and (2). In these calculations, we did not make any simplifying assumptions concerning the degree of degeneracy or relativity of the electron gas. The table with our numerical results can be found on the web, http://www.ioffe.ru/astro/NSG/plasmon/table.dat (file table.dat). This table is described in Appendix B.

The emissivities $Q_l$ and $Q_t$ depend on two parameters characterizing stellar matter. For example, one may choose $T$ and $n_e$ or $T$ and $\rho$ as proper parameters. Following previous results (see, e.g., Itoh et al. 1992), we take $T$ and $\rho$ as independent variables. It is convenient to introduce the notation $f \equiv \hbar \omega_p/(k_B T)$.

The expression for the plasma frequency in the Braaten-Segel approximation has the form (see Braaten & Segel 1993)

$$\omega_p^2 = \frac{4\alpha}{\pi} \frac{e^2}{R^2} \int_0^\infty dp \frac{p^2}{E} \left( 1 - \frac{1}{3} v^2 \right) \left[ n_F(E) + \bar{n}_F(E) \right],$$

(5)

where $p$, $v = pc/E$, and $E = \sqrt{p^2c^2 + m_e^2c^4}$ are, respectively, the momentum, dimensionless velocity, and energy of an electron or positron; $n_F(E) = 1/\{\exp[(E - \mu)/(k_B T)] + 1\}$ is the Fermi-Dirac distribution for electrons; $\bar{n}_F(E) = 1/\{\exp[(E + \mu)/(k_B T)] + 1\}$ is the Fermi-Dirac distribution for positrons; $\mu$ is the electron chemical potential.

In the region of relativistic temperatures ($k_B T \gg m_e c^2$) and under the condition $k_B T \gg$
$p_F c$, the plasma frequency has the asymptote

$$\omega^2_p = \frac{4\pi\alpha (k_B T)^2}{9 \hbar^2}. \quad (6)$$

Here $p_F \equiv (3\pi^3 \hbar^3 n_e)^{1/3}$. For a degenerate electron gas $p_F$ is the usual Fermi momentum of the electrons.

In the case when (i) the electron gas is degenerate ($k_B T \ll \sqrt{p_F^2 c^2 + m_e c^4} - m_e c^2$ and the contribution of positrons to $\omega_p$ can be neglected), or (ii) the gas is non-degenerate, non-relativistic, and the temperature is not too high for the appearance of positrons [see, e.g., Landau & Lifshitz 1980, section 105], expression (5) reduces to

$$\omega^2_p = \frac{4\pi c^3}{3\pi \hbar^2} \frac{p_F^2}{\sqrt{p_F^2 c^2 + m_e^2 c^4}}. \quad (7)$$

If the gas is non-relativistic ($p_F \ll m_e c$), then this equation gives the well-known result,

$$\omega^2_p = 4\pi^2 n_e/m_e.$$

Notice that, since the contribution of the positrons to the asymptote (7) is negligible ($n_{e+} \ll n_e$), $p_F$ in this case can be approximately calculated as $p_F \approx [3\pi^2 h^3 (n_e - n_{e+})]^{1/3} = (3\pi^2 h^3 \tilde{\rho}/m_u)^{1/3}$ (see equation 4). Introducing a new dimensionless parameter, $\tilde{p}_F \equiv (h/m_e c) (3\pi^2 \tilde{\rho}/m_u)^{1/3},$ one can substitute $(m_e c \tilde{p}_F)$ for $p_F$ in the asymptote (7).

Braaten & Segel (1993) developed a useful approximate method to calculate the emissivity due to plasmon decay. Below in this section we present some results obtained using this method (more details are given in the original paper of the authors).

Using the method of Braaten & Segel, the emissivity can be expressed through the parameter $v_*$, which is a characteristic dimensionless velocity of electrons scaling from 0 in the non-relativistic limit to 1 in the ultrarelativistic limit,

$$v_* = \frac{\omega_1}{\omega_p}. \quad (8)$$

Here, the plasma frequency $\omega_p$ is given by equation (5) while the frequency $\omega_1$ is

$$\omega_1^2 = \frac{4\alpha c^3}{\pi \hbar^2} \int_0^\infty dp \frac{p^2}{E} \left( \frac{5}{3}v^2 - v^4 \right) \left[ n_F(E) + \Pi_F(E) \right]. \quad (9)$$

In two limiting cases the neutrino emissivity due to decay of longitudinal and transverse plasmons can be calculated analytically. If the plasma frequency is much smaller than the temperature [$f \equiv \hbar \omega_p/(k_B T) \ll 1$], then equations (11) and (12) can be simplified and written as

$$Q_l = Q_0 \left( \frac{k_B T}{m_e c^2} \right)^9 4\zeta_3 \beta^6 f^6, \quad (10)$$

$$Q_l = Q_0 \left( \frac{k_B T}{m_e c^2} \right)^9 A(v_*) f^8. \quad (11)$$
The neutrino emission due to plasmon decay and neutrino luminosity of white dwarfs

Here, $\zeta_3 \simeq 1.202057$ is a value of the Riemann zeta-function and the function $\beta(v_*)$ equals

$$\beta = \left[ \frac{3}{2 v_*^2} \left( 1 - \frac{1 - v_*^2}{2 v_*} \ln \frac{1 + v_*}{1 - v_*} \right) \right]^{1/2}. \quad (12)$$

In the non-relativistic limit ($v_* \to 0$) it reduces to $\beta = 1$, while in the ultra-relativistic limit ($v_* \to 1$) one has $\beta = \sqrt{3/2}$. Furthermore, $A(v_*)$ is a smooth function of $v_*$, changing from $8/105 \approx 0.076$ at $v_* \to 0$ to 0.349 at $v_* \to 1$. If the plasma frequency is much greater than the temperature ($f \gg 1$), then the integrals (1) and (2) can be taken analytically,

$$Q_t = Q_0 \left( \frac{k_B T}{m_e c^2} \right)^9 b_1 f^7.5 \exp(-f), \quad (13)$$

$$Q_1 = Q_0 \left( \frac{k_B T}{m_e c^2} \right)^9 b_2 f^7.5 \exp(-f), \quad (14)$$

where $b_1 = \sqrt{2\pi} (1 + v_*^2/5)^{-3/2}$ and $b_2 = \sqrt{\pi/2} (3v_*^2/5)^{-3/2}$.

### 3 FIT FOR PLASMA FREQUENCY

To simplify subsequent analysis we derived an analytical formula which approximates the plasma frequency (5) in a wide range of temperatures $T = (10^7 - 10^{11})$ K and effective densities $\bar{\rho} = (2 \times 10^2 - 10^{14})$ g cm$^{-3}$. This range of parameters includes all possible limiting cases of degenerate, ultrarelativistic, as well as of non-degenerate non-relativistic electron gas. We calculated the emissivity on a dense grid of mesh points (with the steps 0.2 in lg $T$ and lg $\bar{\rho}$). The root mean-square relative error of our approximation is 0.4%. The maximum error of 1.4% is at lg $T = 9.0$ (K) and lg $\bar{\rho} = 2.4$ (g cm$^{-3}$). The fit reproduces the asymptotes from Section 2. The squared plasma frequency can be approximated as

$$\omega_p^2 = \left( \frac{m_e c^2}{\hbar} \right)^2 \sqrt{\text{asy}_1} + \text{asy}_2 \left( 1 - C \right). \quad (15)$$

Here, $\text{asy}_1 = 4\alpha/(3\pi) \tilde{\rho}_F / \sqrt{1 + \tilde{\rho}_F^2}$ is exactly the low-temperature asymptote (6) [we recall that $\tilde{\rho}_F = (\hbar/m_e c) (3\pi^2 \tilde{\rho}/m_u)^{1/3}$], while $\text{asy}_2$ is given by

$$\text{asy}_2 = \frac{4\pi\alpha}{9} p_2 \left( \frac{p_2}{t} + 1 + \frac{p_2}{t^2} \right) \left[ 1 + \frac{p_3}{(t/\sqrt{p_2})^{p_1}} \right]^{-10}, \quad (16)$$

with $t \equiv k_B T/(m_e c^2)$. In the high-temperature limit, $\text{asy}_2$ transforms into the asymptote (6). The fit parameters $p_1$, $p_2$, and $p_3$ equal $p_1 = 1.793$, $p_2 = 0.0645$, and $p_3 = 0.433$.

The function $C$ in equation (15) is written as

$$C = 1 - c_2 \left( \frac{c_1 t^2}{1 + (c_1 t)^2} \right), \quad (17)$$
where
\begin{align*}
c_1 &= p_4 \frac{1 + p_5 \tilde{\rho}^6}{1 + p_7 (1 + p_5 \tilde{\rho}^6)}, \\
c_2 &= p_8 + p_9 \frac{\tilde{\rho}}{p_{10} + \tilde{\rho}},
\end{align*}
(18)
(19)
with $p_4 = 0.01139$, $p_5 = 2.484 \times 10^6$, $p_6 = -0.6195$, $p_7 = 0.0009632$, $p_8 = 0.4372$, $p_9 = 1.614$, and $p_{10} = 8.504 \times 10^8$.

At low temperatures the plasma frequency in the first approximation depends only on $\tilde{\rho}$ and we have $C = 1$. The function $D$ in equation (15) has the form
\begin{align*}
D &= \frac{t^2}{d_1 \sqrt{1 + (d_2 t)^2}}, \\
d_1 &= \frac{6}{\pi^2} \frac{p_F^2 (1 + \tilde{p}_F^2)}{2p_F^2 + 5}, \\
d_2 &= \frac{\pi^2}{6} \frac{1}{\sqrt{1 + \tilde{p}_F^2} - 1}.
\end{align*}
(20)
(21)
At high temperatures (when $t \gg 1$ and the electron gas is non-degenerate) the fit (15) reproduces the high-temperature asymptote (6). At low temperatures (a degenerate gas or a non-degenerate non-relativistic gas; positrons can be neglected) the fit (15) transforms into the analytical asymptote (7), which depends only on $\tilde{\rho}$. The function $D$ is designed in such a way to reproduce not only the asymptote (7) of plasma frequency but also the first temperature corrections to $\omega_p$. For a degenerate electron gas, the expansion parameter is $k_B T / \mu$; for the non-degenerate non-relativistic gas it reduces to $k_B T / (m_e c^2)$.

4 FIT FOR THE NEUTRINO EMISSIVITY

In this section we present an analytical formula which approximates the results of numerical calculations of the emissivity $Q = Q_t + Q_l$ (per unit volume) and reproduces the asymptotes from Section 2. The approximation was made in a range of temperatures $T = (10^7 - 10^{11})$ K and effective densities $\tilde{\rho} = (2 \times 10^2 - 10^{14})$ g cm$^{-3}$. The emissivity $Q(\tilde{\rho}, T)$ was calculated on the same grid points as the plasma frequency (Section 3). At $f \equiv \hbar \omega_p / (k_B T) > 20$ the accuracy of our fit is only logarithmic. However, in this case the emissivity $Q$ is exponentially small, $Q \sim \exp(-f)$.

The fit for the emissivity can be presented in the form
\begin{align*}
Q &= Q_t + Q_t = Q_0 t^9 (W_t + W_l) \exp(-f),
\end{align*}
(22)
The neutrino emission due to plasmon decay and neutrino luminosity of white dwarfs

where, as before, \( t \equiv k_B T / (m_e c^2) \) and we define

\[
W_1 \equiv \text{asy}_{11} + \text{asy}_{12} \exp \left[ \frac{q_3}{(f q_1 + q_2)} \right],
\]

\[
W_1 \equiv \frac{\text{asy}_{12} \left[ \text{asy}_{11} + q_4 \left( 1 + q_5 \nu_{*}^{2.5} \right)^3.5 f^9 \right]}{\text{asy}_{12} + \left[ \text{asy}_{11} + q_4 \left( 1 + q_5 \nu_{*}^{2.5} \right)^3.5 f^9 \right]}.
\]

In equations (23) and (24)

\[
\text{asy}_{11} = a_1 f^6, \quad \text{asy}_{11} = a_2 f^8,
\]

\[
\text{asy}_{12} = b_1 f^{7.5}, \quad \text{asy}_{12} = b_2 f^{7.5},
\]

\[
a_1 = 4 \zeta_3 \beta^6, \quad a_2 = \frac{8}{105} + \left( 0.349 - \frac{8}{105} \right) \nu_{*}^{10},
\]

the functions \( b_1(v_*) \) and \( b_2(v_*) \) are the same as in equations (13) and (14); the function \( \beta(v_*) \) is given by equation (12). At \( f \ll 1 \) equation (22) transforms into

\[
Q = Q_t = Q_0 t^9 \text{asy}_{11} = Q_0 t^9 4 \zeta_3 \beta^6 f^6
\]

(compare with the asymptotes 10 and 11). At \( f \gg 1 \) one has

\[
Q = Q_0 t^9 (\text{asy}_{12} + \text{asy}_{12}) \exp(-f) = Q_0 t^9 (b_1 + b_2) f^{7.5} \exp(-f)
\]

(compare with the asymptotes 13 and 14).

When calculating the emissivity from equation (22) one should use the fit (15) for the plasma frequency \( \omega_p \) and the following fit for the characteristic velocity \( v_* \),

\[
v_* = \left( \frac{\overline{\nu}_F^3 + s_1 t^2 \overline{\rho}_s^3}{1 + s_1 t^2 \overline{\rho}_s^3} \right)^{1/3},
\]

where \( \overline{\nu}_F \equiv \overline{\nu}_F / \sqrt{1 + \overline{\rho}_s}; \ s_1 = 9.079; \ s_2 = 1.399; \ s_3 = -0.06592 \). The root mean-square relative error of this approximate formula in the chosen range of \( T \) and \( \overline{\rho} \) constitutes 1.4%. The maximum fit error is equal to 5.4% at \( \lg T = 8.4 \) (K) and \( \lg \overline{\rho} = 3.8 \) (g cm\(^{-3}\)).

In addition, it turns out to be necessary to use a special approximate formula for the function \( \beta^6(v_*) \) from which the fitting expression (22) depends on [a simple substitution of equation (30) into (12) and subsequent calculation of \( \beta^6 \) results in large errors],

\[
\beta^6 = \beta^6(\overline{\nu}_F) + \left[ 3.375 - \beta^6(\overline{\nu}_F) \right] \frac{t r_2 \overline{\rho}_s^3}{(r_1 + t r_2 \overline{\rho}_s^3)}
\]

where \( r_1 = 0.3520; \ r_2 = 1.195; \ r_3 = -0.1060 \). The root mean-square relative error of this fit constitutes 2.5%, the maximum error of 8.3% is at \( \lg T = 9.6 \) (K) and \( \lg \overline{\rho} = 5.0 \) (g cm\(^{-3}\)). The function (31) was approximated in the same temperature and density range as the parameter \( v_* \) and the emissivity \( Q \).

The use of approximate formulae (15) and (30)–(31) leads to the following values of fitting parameters \( q_1, \ldots, q_5 \) (see equations (23) and (24), minimizing root mean-square deviation of
the emissivity, provided by equation (22), from the numerical values,

\[ q_1 = 0.7886, \quad q_2 = 0.2642, \]
\[ q_3 = 1.024, \quad q_4 = 0.07839, \quad q_5 = 0.1784. \]  

(32)

The root mean-square relative error of the approximate formula (22) with these coefficients is 4%, the maximum error is 7.9% at \( \lg T = 8.4 \) and \( \lg \rho = 6.4 \).

In Fig. 2 we compare our numerical results for the emissivity \( Q_{num} \) with the results taken from the literature (corresponding emissivities are denoted as \( Q_{lit} \)). The figure presents the relative deviation \( \delta \equiv (Q_{lit} - Q_{num})/Q_{num} \) as a function of \( \rho \) for a set of temperatures \( T = 10^7, 10^8, 10^9, \) and \( 10^{10} \) K. The solid curves demonstrate relative deviations of the approximation (22), suggested in this paper, from our numerical results \( Q_{num} \); the long dashes show deviations from numerical calculations of Itoh et al. (1992) [taken from their table]; the dotted curves correspond to relative deviations calculated using an approximate formula, suggested by Itoh et al. (1992); the short dashes describe relative deviations calculated from...
The neutrino emission due to plasmon decay and neutrino luminosity of white dwarfs

a fitting formula of Haft et al. (1994). Finally, by the dot-dashed curves we show relative deviations calculated from the approximate formula for the emissivity given in the review of Yakovlev et al. (2001). In that review it is recommended to use the formula only for \( \rho > 10^8 \text{ g cm}^{-3} \) and for strongly degenerate electrons. From the analysis of Fig. 2 a number of conclusions can be inferred:

(i) The approximate formula obtained in this section is in good agreement with the results of numerical calculations as long as \( f < 20 \) (at greater \( f \), that is at higher densities, the solid curve tends to go upward).

(ii) Our calculations agree with results of Itoh et al. (1992) in the range of parameters, where the electron gas is strongly degenerate and the emissivity is not small. However, as follows, for example, from Fig. 2 at \( T = 10^9 \text{ K} \), some our results deviate from those of Itoh et al. (1992) for \( \rho \sim 10^{13} \text{ g cm}^{-3} \). For this case, matter is strongly degenerate so that the simplified assumptions, made by Itoh et al. at calculating the emissivity, could not lead to such deviations. (Let us note that Itoh et al. used the dielectric function, calculated by Jancovici 1962 for a strongly degenerate electron gas, see Appendix A.) Taking into account that our numerical results at such densities and \( T = 10^9 \text{ K} \) do not differ from the analytical asymptote for the emissivity by more than 10%, the results of Itoh et al. (1992) in the indicated parameter range seem less accurate than ours.

(iii) The fit formula of Itoh et al. (1992) satisfactorily describes the results of numerical calculations only near the maximum of the emissivity (when \( f \sim 1 \)).

(iv) The fit formula of Haft et al. (1994) agrees well with our numerical results in the same region of temperatures and densities in which the numerical results of Itoh et al. (1992) agrees with our numerical results.

(v) The approximate formula from the review of Yakovlev et al. (2001) becomes inaccurate at high temperatures (i.e., \( T = 10^{10} \text{ K} \)) and low densities (\( \rho \sim 10^8 \text{ g cm}^{-3} \)). This approximate formula is valid only for strongly degenerate electrons, while the electron degeneracy becomes mild at high \( T \) and low \( \rho \).

Summarizing, as follows from Fig. 2, the results of various authors are in satisfactory agreement in the ranges of \( T \) and \( \rho \) where the process of neutrino emission due to plasmon decay is the most efficient mechanism of energy losses in dense stellar matter.
Let us apply the results of Section 4 to analyze the neutrino luminosity of white dwarfs. As will be argued below, the neutrino luminosity due to plasmon decay only weakly depends on a specific model of a white dwarf. Thus, it can be considered as a universal function of the white dwarf mass $M$ and its internal temperature $T$. Here we calculate this universal function and approximate it by a convenient analytical formula.

As is well known, the thermal evolution of a white dwarf consists of two stages, the neutrino cooling stage (where cooling is mainly realized through the neutrino emission from the entire stellar body) and the photon stage (the main energy losses through the photon radiation from the stellar surface). A transition from one stage to the other occurs at the stellar age $\tau \sim (10^7 - 10^8) \text{ yr}$, when the surface temperature of a star equals $T_s \sim 2.5 \times 10^4 \text{ K}$ (for a hydrogen or helium atmosphere white dwarf, see, e.g., Winget et al. 2004).

At the neutrino cooling stage the main mechanism of energy losses is the neutrino emission due to plasmon decay (the second important process – the neutrino bremsstrahlung in collisions of electrons with atomic nuclei – is 10–100 times weaker, see Winget et al. 2004). We numerically calculated the neutrino luminosity $L_\nu(M, T)$ of white dwarfs caused by the decay of plasmons. When doing the calculation, we made the following assumptions. First, to obtain the density profile inside a white dwarf we assumed that the pressure is fully determined by degenerate electrons. Second, the stellar core was assumed to be isothermal, which is a good approximation for not too young white dwarfs ($\tau \gtrsim 10 - 1000 \text{ yr}$). Third, we neglected beta-captures when calculating the structure and luminosity of massive white dwarfs. Beta-captures lead to softening of the equation of state, and influence the hydrostatic structure of a star. In addition, they change stellar chemical composition, affect the number of nucleons per one electron, $\mu_e$, and, consequently, the quantities $\rho$ and $L_\nu$. However, because the neutrino luminosity is the integral characteristic of a star, it should not strongly depend on these simplified assumptions.

In Fig. 3 we present the neutrino luminosity $L_\nu$ as a function of stellar core temperature $T$ for white dwarfs with the masses $M = 0.4 M_\odot, 0.6 M_\odot, M_\odot,$ and $1.4 M_\odot$.

The results of numerical calculations of $L_\nu$ in the range of temperatures $T = (3 \times 10^7 - 5 \times 10^8) \text{ K}$ and masses $M = (0.4 - 1.3) M_\odot$ were approximated by the formula

$$L_{\nu 1}(M, T) = 10^{39} \frac{k_1 T_8^{31/3}(k_4 \tilde{M}^{k_2} + \tilde{M}^{k_1})(1 + k_5 \tilde{M})^{22/3}}{[k_6 (1 + k_5 \tilde{M})^{22/(3 k_7)} T_8^{22/(3 k_7)} + \tilde{M}^{22/(3 k_7)}]^{k_7}} \text{ erg s}^{-1},$$

(33)
The neutrino emission due to plasmon decay and neutrino luminosity of white dwarfs

Figure 3. The neutrino luminosity $L_\nu$ versus internal stellar temperature $T$ for white dwarfs with $M = 0.4M_\odot$, $0.6M_\odot$, $M_\odot$, and $1.4M_\odot$.

where $\tilde{M} = M/M_\odot$, $T_8 = T/(10^8 K)$, and

$$k_1 = 1.050, \quad k_2 = 11.86, \quad k_3 = 5.901,$$
$$k_4 = 1.010, \quad k_5 = -0.5448, \quad k_6 = 2.777, \quad k_7 = 5.635.$$  \hfill (34)

For white dwarfs with $M = (1.3 - 1.4)M_\odot$ the neutrino luminosity in the same range of temperatures $T = (3 \times 10^7 - 5 \times 10^8)$ K is given by

$$L_{\nu^2}(M, T) = 10^{39} \frac{l_1 T_8^{31/3} \tilde{M}^{l_2}}{\left(l_3 T_8^{22/(3l_3)} + \tilde{M}^{22l_4/(3l_5)}\right)^{l_5}} \text{ erg s}^{-1},$$  \hfill (35)

where

$$l_1 = 2.777, \quad l_2 = 25.13, \quad l_3 = 3.095, \quad l_4 = 7.585, \quad l_5 = 7.381.$$  \hfill (36)

The maximum error of the fit expressions (33) and (35) does not exceed 14%. Unfortunately, these two approximations do not match at $M = 1.3M_\odot$. Thus, to calculate the neutrino emissivity for a white dwarf with the mass $M \in [1.28M_\odot, 1.32M_\odot]$, we recommend to use a linear interpolation

$$L_{\nu^3}(M, T) = L_{\nu^1}(1.28M_\odot, T) + \frac{L_{\nu^2}(1.32M_\odot, T) - L_{\nu^1}(1.28M_\odot, T)}{0.04} (\tilde{M} - 1.28).$$  \hfill (37)

This interpolation does not affect the maximum fit error which remains to be 14% at $T = 2.38 \times 10^8$ K and $M = 1.34M_\odot$.

As seen from equations (33) and (35), in the limit of high temperatures $L_\nu \sim T^3$, while in
the limit of low temperatures $L_\nu \sim T^{31/3}$. Let us demonstrate how to obtain this temperature dependence from simple physical arguments.

At high temperatures, the internal stellar temperature $T$ is much greater than the plasma frequency $\omega_{p0}$ in the center of the star. Since the plasma frequency of degenerate electrons becomes smaller as the density decreases (see equation 7), we have $k_B T \gg \hbar \omega_p$ throughout the star. In this case the neutrino emissivity of an arbitrary volume element in the star is given by asymptote (28) and the luminosity equals

$$L_\nu \approx 4\xi_3 \frac{\hbar^6 k_B^3}{(m_e c^2)^6} Q_0 T^3 \int_{\text{star}} \beta^6 \omega_p^6 dV.$$ \hspace{1cm} (38)

Here the integral is taken over the volume $V$ of the star. Since the plasma frequency $\omega_p$ and the parameter $\beta$ depend only on $\tilde{\rho}$ (see equations 7 and 12), one gets $L_\nu \propto T^3$.

In the low-temperature limit, when $k_B T \ll \hbar \omega_{p0}$, the main contribution to the luminosity comes from a thin spherical layer of width $h$, in which $h \omega_p \sim k_B T$. This layer is situated in the outermost part of the stellar core, where the electrons form a degenerate, non-relativistic gas. Indeed, if we move from this layer to the stellar center, $\omega_p$ will increase while the emissivity will be exponentially suppressed, $Q \sim \exp(-\hbar \omega_p/k_B T)$, in accordance with equation (29). If we move from the layer to the stellar surface then the emissivity will also decrease (see asymptote 28) but in a power-law fashion, $Q \sim \beta^6 \omega_p^6 = \omega_p^6 (\beta = 1$ for the non-relativistic electron gas, see equation 12). Therefore, the emissivity will have a maximum in a layer in which $\hbar \omega_p \sim k_B T$, and the neutrino luminosity of a star can be estimated as

$$L_\nu \sim 4\xi_3 \beta^6 Q_0 \left( \frac{k_B T}{m_e c^2} \right)^9 \left( \frac{\hbar \omega_p}{k_B T} \right)^6 4\pi R^2 h \sim 16\pi \xi_3 Q_0 \left( \frac{k_B T}{m_e c^2} \right)^9 R^2 h,$$ \hspace{1cm} (39)

where $R$ is the white dwarf radius. An order of magnitude estimate gives the characteristic width $h$ of the layer, $h \sim \omega_p^6/(d \omega_p^6/dr)$. Using the hydrostatic equilibrium equation and the scaling relations for the plasma frequency (see equation 7) $\omega_p \propto \tilde{\rho}^{1/2}$ and pressure $P \propto \tilde{\rho}^{5/3}$ of the degenerate non-relativistic gas, we get $h \propto \tilde{\rho}^{2/3} \propto \omega_p^{4/3} \propto T^{4/3}$. Consequently, $L_\nu \propto T^{31/3}$, in agreement with the estimate (39).

Let us note that the plasmon decay neutrino emissivity and hence the luminosity of the star depend on the effective density $\tilde{\rho}$, which is related to the real density $\rho$ by equation (3), $\tilde{\rho}/\rho = 1/\mu_e = \sum_i Z_i n_i / (\sum_i A_i n_i)$. In white dwarfs with any reasonable chemical composition, the mass number $A_i$ of atomic nuclei species $i$ is always twice as much than the charge number $Z_i$ (recall that we neglect beta-captures). Thus, the ratio $\tilde{\rho}/\rho$ is equal to 1/2. We used this ratio in all our calculations.
6 SUMMARY

We have calculated the neutrino emissivity $Q$ due to plasmon decay in an electron-positron plasma making no assumptions about degree of degeneracy or relativity of the electron gas.

When calculating the emissivity one needs the plasma dielectric functions as well as the dispersion relations for transverse and longitudinal plasmons in a wide range of temperatures and densities. In particular, we have calculated the plasma frequency $\omega_p$ and fitted it by an analytical formula. This formula reproduces the main asymptotes for $\omega_p$ (degenerate, ultrarelativistic or non-degenerate non-relativistic electrons, see Section 3).

The results of numerical calculations of the neutrino emissivity were also approximated by a convenient analytical expression. It satisfies the asymptotes in various limiting cases (Section 4, also see the paper by Braaten & Segel 1993). The approximation is valid for $T = (10^7 - 10^{11})$ K and $\tilde{\rho} = (2 \times 10^2 - 10^{14})$ g cm$^{-3}$. The root mean-square relative error of the approximation does not exceed 4% for those temperatures and densities, for which $f = \hbar \omega_p/(k_B T) < 20$ [while at $f > 20$ the emissivity is exponentially small, $Q \sim \exp(-f)$].

The fit expression for the emissivity was used to calculate the neutrino luminosity of white dwarfs (Section 5). This neutrino luminosity was fitted by analytic formulas and presented as a function of white dwarf mass and its internal temperature. It is shown that the neutrino luminosity depends on the chemical composition of a white dwarf only through the parameter $\mu_e$ which is equal to 2 for reasonable white dwarf compositions.

The results of this paper can be used in a number of applications, in particular, in modelling of the evolution of red giants or presupernovae as well as in the cooling theory of white dwarfs (see, e.g., Haft et al. 1994, Winget et al. 2004).

ACKNOWLEDGMENTS

The authors are grateful to D.G. Yakovlev for discussions; to our referee, Agnes Kim, for valuable suggestions and comments; to A.I. Chugunov for providing the code that was used to approximate numerical results by analytical functions; to A.Y. Potekhin for calculating the relation between the surface and internal temperatures of helium atmosphere white dwarfs; and to D.P. Barsukov and A.M. Krassilchtchikov for technical assistance. This research was supported by RFBR (grants 05-02-16245 and 05-02-22003) and by the Federal Agency for Science and Innovations (grant NSh 9879.2006.2).
APPENDIX A: DIELECTRIC FUNCTIONS OF ELECTRON-POSITRON PLASMA

Using the density matrix formalism we calculated the dielectric function of the electron-positron gas in the first order of perturbation theory. The longitudinal \( \varepsilon_l(\omega, k) \) and transverse \( \varepsilon_t(\omega, k) \) components of the dielectric tensor can be written in the form \((c = \hbar = k_B = 1)\)

\[
\varepsilon_l = 1 - \frac{4\pi\alpha}{\omega^2} \sum_{e^-,e^+} \int \frac{d^3p}{(2\pi)^3} \frac{1}{E_{p+k} E_p} \frac{n_{p+k} - n_p}{E_{p+k} - E_p - \omega - i\delta} \times \left[ \frac{2(p \cdot k)^2}{k^2} + (p \cdot k) + E_{p+k} E_p - E_p^2 \right],
\]

\[
\varepsilon_t = 1 - \frac{4\pi\alpha}{\omega^2} \sum_{e^-,e^+} \int \frac{d^3p}{(2\pi)^3} \frac{1}{E_{p+k} E_p} \frac{n_{p+k} - n_p}{E_{p+k} - E_p - \omega - i\delta} \times \left[ \frac{(p \times k)^2}{k^2} - (p \cdot k) + E_{p+k} E_p - E_p^2 \right].
\]

Here, the summation is carried over electrons and positrons; \( n_p = 1/[\exp(E_p \mp \mu)/T + 1] \) is the Fermi-Dirac distribution function for electrons (in this case one have to choose the sign \(-\)) or positrons (the sign \(+\)); \( E_p = \sqrt{p^2 + m_e^2} \) and \( E_{p+k} = \sqrt{(p + k)^2 + m_e^2} \) is the energy of an electron or a positron with the momentum \( p \) and \( p + k \), respectively.
The neutrino emission due to plasmon decay and neutrino luminosity of white dwarfs

We have checked that equations (A1) and (A2) are equivalent to corresponding expressions for the dielectric function which can be obtained from the polarization tensor $\Pi^{\mu\nu}$ of Braaten and Segel (1993) [see their equation A1].

The integration over the angles in equations (A1) and (A2) can be done analytically. As a result, one obtains for real parts of $\varepsilon_l$ and $\varepsilon_t$,

$$
\varepsilon_l = 1 - \frac{\alpha}{\pi \omega^2} \int_0^\infty dp \, p^2 \left[ n_F(E_p) + \bar{n}_F(E_p) \right] R_l, \\
\varepsilon_t = 1 - \frac{\alpha}{\pi \omega^2} \int_0^\infty dp \, p^2 \left[ n_F(E_p) + \bar{n}_F(E_p) \right] R_t,
$$

where

$$
R_l = -\frac{4\omega^2}{E_p k^2} + \frac{\omega^2}{2E_p^3 k^3} \left[ (2E_p + \omega)^2 - k^2 \right] \ln \left| \frac{E_{p-k}^2 - (E_p + \omega)^2}{E_{p+k}^2 - (E_p + \omega)^2} \right| \\
+ \frac{\omega^2}{2E_p^3 k^3} \left[ (2E_p - \omega)^2 - k^2 \right] \ln \left| \frac{E_{p-k}^2 - (E_p - \omega)^2}{E_{p+k}^2 - (E_p - \omega)^2} \right|, \\
R_t = \frac{2 (\omega^2 + k^2)}{E_p k^2} + \frac{1}{4E_p^3 k^3} \left[ k^4 + 4k^2 p^2 + 4k^2 E_p \omega - \omega^2 (2E_p + \omega)^2 \right] \ln \left| \frac{E_{p-k}^2 - (E_p + \omega)^2}{E_{p+k}^2 - (E_p + \omega)^2} \right| \\
+ \frac{1}{4E_p^3 k^3} \left[ k^4 + 4k^2 p^2 - 4k^2 E_p \omega - \omega^2 (2E_p - \omega)^2 \right] \ln \left| \frac{E_{p-k}^2 - (E_p - \omega)^2}{E_{p+k}^2 - (E_p - \omega)^2} \right|.
$$

In equations (A3)–(A6) $n_F(E_p)$ and $\bar{n}_F(E_p)$ are the Fermi-Dirac distribution functions for electrons and positrons, respectively; $E_{p\pm k} = \sqrt{(p \pm k)^2 + m^2_e}$ is the energy of an electron or a positron with the absolute value of momentum equal to $(p \pm k)$.

Knowing the dielectric functions, the plasmon dispersion relations can be found from the equations

$$
\varepsilon_l(\omega, k) = 0, \quad \omega^2 \varepsilon_t(\omega, k) = k^2.
$$

If the electron gas is completely degenerate ($T = 0$), then the integrals in equations (A3)
and (A11) can be taken analytically. The result is

\[
\varepsilon_1 = 1 - \frac{\alpha}{\pi} \left\{ -\frac{8}{3} \frac{1}{k_F^2} p_F \sqrt{p_F^2 + m_e^2} + \frac{2}{3} \sinh^{-1} \frac{p_F}{m_e} \right. \\
+ \frac{1}{3} \left( k^2 - \omega^2 - 2m_e^2 \right) \sqrt{\frac{k^2 - \omega^2 + 4m_e^2}{\omega^2 - k^2}} L_1 \\
- \frac{1}{6k^3} \omega \left( 3\omega^2 - 3k^2 + 4p_F^2 + 4m_e^2 \right) L_2 \\
+ \frac{\omega}{12k^3} \left( \omega^2 - 3k^2 + 12p_F^2 + 12m_e^2 \right) L_3 \right\} , \tag{A8}
\]

\[
\varepsilon_t = 1 - \frac{\alpha}{\pi \omega^2} \left\{ \frac{2}{3} \frac{(k^2 + 2\omega^2)}{k^2} p_F \sqrt{p_F^2 + m_e^2} \\
- \frac{2}{3} (k^2 - \omega^2) \sinh^{-1} \frac{p_F}{m_e} \\
- \frac{(k^2 - \omega^2 - 2m_e^2)}{3} \sqrt{\frac{k^2 - \omega^2 + 4m_e^2}{\omega^2 - k^2}} L_1 \\
+ \frac{\sqrt{p_F^2 + m_e^2}}{k^3} \left[ -\frac{1}{3} (k^2 - \omega^2) (p_F^2 + m_e^2) + \frac{1}{4} (-k^4 + \omega^4 + 4m_e^2 k^2) \right] L_2 \\
+ \frac{\omega}{24k^3} \left[ (k^2 - \omega^2) \left( 3k^2 + \omega^2 + 12p_F^2 + 12m_e^2 \right) - 12m_e^2 k^2 \right] L_3 \right\} . \tag{A9}
\]

The quantities \( L_2 \) and \( L_3 \) are

\[
L_2 = \ln \left| \frac{(-k^2 + \omega^2 - 2k p_F)^2 - 4\omega^2(p_F^2 + m_e^2)}{(-k^2 + \omega^2 + 2k p_F)^2 - 4\omega^2(p_F^2 + m_e^2)} \right|, \tag{A10}
\]

\[
L_3 = \ln \left| \frac{(-k^2 + \omega^2)^2 - 4(\omega \sqrt{p_F^2 + m_e^2} + k p_F)^2}{(-k^2 + \omega^2)^2 - 4(\omega \sqrt{p_F^2 + m_e^2} - k p_F)^2} \right| . \tag{A11}
\]

The quantity \( L_1 \) depends on the sign of \( D \equiv (\omega^2 - k^2)(k^2 - \omega^2 + 4m_e^2) \). At \( D \geq 0 \) one has

\[
L_1 = \arctan \left[ \frac{-2m_e k p_F + (k^2 + 2m_e \omega - \omega^2) \left( \sqrt{p_F^2 + m_e^2} - m_e \right)}{p_F \sqrt{\omega^2 - k^2} (k^2 - \omega^2 + 4m_e^2)} \right] \\
+ \arctan \left[ \frac{2m_e k p_F + (k^2 + 2m_e \omega - \omega^2) \left( \sqrt{p_F^2 + m_e^2} - m_e \right)}{p_F \sqrt{\omega^2 - k^2} (k^2 - \omega^2 + 4m_e^2)} \right] \\
+ \arctan \left[ \frac{-2m_e k p_F + (k^2 - 2m_e \omega - \omega^2) \left( \sqrt{p_F^2 + m_e^2} - m_e \right)}{p_F \sqrt{\omega^2 - k^2} (k^2 - \omega^2 + 4m_e^2)} \right] \\
+ \arctan \left[ \frac{2m_e k p_F + (k^2 - 2m_e \omega - \omega^2) \left( \sqrt{p_F^2 + m_e^2} - m_e \right)}{p_F \sqrt{\omega^2 - k^2} (k^2 - \omega^2 + 4m_e^2)} \right]. \tag{A12}
\]

At \( D < 0 \)

\[
L_1 = \frac{i}{2} \ln \left| \frac{(k^2 - \omega^2) \sqrt{p_F^2 + m_e^2} + p_F \sqrt{(k^2 - \omega^2)(k^2 - \omega^2 + 4m_e^2)}^2 - 4m_e^4 \omega^2}{(k^2 - \omega^2) \sqrt{p_F^2 + m_e^2} - p_F \sqrt{(k^2 - \omega^2)(k^2 - \omega^2 + 4m_e^2)}^2 - 4m_e^4 \omega^2} \right|. \tag{A13}
\]
The neutrino emission due to plasmon decay and neutrino luminosity of white dwarfs

Note, that equations (A8) and (A9) for the dielectric functions agree with the well known results of Jancovici (1962) only at $D < 0$ (see his equations A1 and A4). At $D \geq 0$ his expressions (A1) and (A4) are formally inapplicable (the real part of the dielectric functions in these equations becomes complex). In this case one should use our equations (A8) and (A9).

In addition, it may be useful to note, that the Jancovici's definition of the transverse dielectric function differs from a generally accepted one. His dielectric function $\varepsilon^\text{Janc}_t$ is related to our dielectric function by $\varepsilon^\text{Janc}_t = (k^2 - \omega^2 \varepsilon_t)/(k^2 - \omega^2)$.

**APPENDIX B: DESCRIPTION OF A TABLE OF OUR NUMERICAL RESULTS**

The results of our numerical calculations are summarized in the table (file table.dat) which can be found on the web: [http://www.ioffe.ru/astro/NSG/plasmon/table.dat](http://www.ioffe.ru/astro/NSG/plasmon/table.dat)

The table consists of seven columns. In the first column, we present $\lg T$ (in kelvins); in the second column we give $\lg(\tilde{\rho}) = \rho/\mu_e$ (g cm$^{-3}$); in the third and fourth columns we present, respectively, the emissivities $Q_t$ and $Q_l$ (erg s$^{-1}$ cm$^{-3}$) due to decay of transverse and longitudinal plasmons; the fifth column is the plasma frequency $\omega_p$ (s$^{-1}$), which is numerically calculated from the exact dispersion relations (A7) [not using the Braaten-Segel approximation]; the sixth column is the same plasma frequency but calculated from equation (5) [the Braaten-Segel approximation]. Finally, in the seventh column we present the characteristic dimensionless velocity of electrons $v_\ast = \omega_1/\omega_p$ in units of $c$, calculated in the Braaten-Segel approximation (i.e. by making use of equations 5 and 9 for $\omega_p$ and $\omega_1$, respectively).

This paper has been typeset from a TEX/LATEX file prepared by the author.
