Abstract
The fractional Hilbert transform was introduced by Zayed [30, Zayed, 1998] and has been widely used in signal processing. In view of its connection with the fractional Fourier transform, Chen, the first, second and fourth authors of this paper in [6, Chen et al., 2021] studied the fractional Hilbert transform and other fractional multiplier operators on the real line. The present paper is concerned with a natural extension of the fractional Hilbert transform to higher dimensions: this extension is the fractional Riesz transform which is defined by multiplication which a suitable chirp function on the fractional Fourier transform side. In addition to a thorough study of the fractional Riesz transforms, in this work we also investigate the boundedness of singular integral operators with chirp functions on rotation invariant spaces, chirp Hardy spaces and their relation to chirp BMO spaces, as well as applications of the theory of fractional multipliers in partial differential equations. Through numerical simulation, we provide physical and geometric interpretations of high-dimensional fractional multipliers. Finally, we present an application of the fractional Riesz transforms in edge detection which verifies a hypothesis insinuated in [26, Xu et al., 2016]. In fact our numerical implementation confirms that amplitude, phase, and direction information can be simultaneously extracted by controlling the order of the fractional Riesz transform.

Keywords fractional Fourier transform, fractional Riesz transform, edge detection, chirp Hardy space, fractional multiplier

1 Introduction

One of the fundamental operators in Fourier analysis theory is the Hilbert transform

\[ H(f)(x) = \frac{1}{\pi} \text{p.v.} \int_{\mathbb{R}} \frac{f(y)}{x-y} dy, \]

which is a continuous analogue of the conjugate Fourier series. The early studies of the Hilbert transform were based on complex analysis methods but around the 1920s these were complemented and enriched by real analysis techniques. The Hilbert transform, being the prototype of singular integrals, provided significant inspiration for the subsequent development of this subject. The work of Calderón and Zygmund \([3]\) in 1952 furnished extensions of singular integrals to \(\mathbb{R}^n\). This theory has left a big impact in analysis in view of its many applications, especially in the field of partial differential equations. Nowadays, singular integral operators are important tools in harmonic analysis but also find many applications in applied mathematics. For instance, the Hilbert transform plays a fundamental role in communication systems and digital signal processing systems, such as in filter, edge detection and modulation theory \([12, 13]\). As the Hilbert transform is given by convolution with the kernel \(1/(\pi t)\) on the real line, in signal processing it can be understood as the output of a linear time invariant system with an impulse response of \(1/(\pi t)\).

The Fourier transform is a powerful tool in the analysis and processing of stationary signals.

**Definition 1.1.** We define the Fourier transform of a function \(f\) in the Schwartz class \(S(\mathbb{R}^n)\) by

\[ \hat{f}(\xi) = \mathcal{F}(f) = \frac{1}{(\sqrt{2\pi})^n} \int_{\mathbb{R}^n} f(x) e^{-ix\xi} dx. \]
In time-frequency analysis, the Hilbert transform is also known as a $\pi/2$-phase shifter. The Hilbert transform can be defined in terms of the Fourier transform as the following multiplier operator

$$
\mathcal{F}(Hf(x)) = -\text{sgn}(x)\mathcal{F}(f(x)).
$$

(1.1)

It can be seen from (1.1) that the Hilbert transform is a phase-shift converter that multiplies the positive frequency portion of the original signal by $-i$; in other words, it maintains the same amplitude and shifts the phase by $-\pi/2$, while the negative frequency portion is shifted by $\pi/2$.

The Riesz transform is a generalization of the Hilbert transform in the $n$-dimensional case and is also a singular integral operator, with properties analogous to those of the Hilbert transform on $\mathbb{R}$. It is defined as

$$
R_j(f)(x) = c_n \text{ p.v.} \int_{\mathbb{R}^n} \frac{x_j - y_j}{|x - y|^{n+1}} f(y) dy, \quad 1 \leq j \leq n,
$$

where $c_n = \Gamma(n/2 + 1)/\pi^{n+1}$. The Riesz transform is also a multiplier operator

$$
\mathcal{F}(R_j f)(x) = -\frac{i x_j}{|x|} \mathcal{F}(f)(x).
$$

**Remark 1.1.** The multiplier of the Hilbert transform is $-\text{sgn}(x)$, and it is simply a phase-shift converter. The multiplier of the Riesz transform is $-ix_j/|x|$, and thus, the Riesz transform is not only a phase-shift converter but also an amplitude attenuator.

The Riesz transform has wide applications in image edge detection, image quality assessment and biometric feature recognition [16, 33, 34].

The Fourier transform is limited in processing and analyzing nonstationary signals. The fractional Fourier transform (FRFT) was proposed and developed by some scholars mainly because of the need for nonstationary signals. The FRFT originated in the work of Wiener in [29]. Namias in [21] proposed the FRFT through a method that was primarily based on eigenfunction expansions in 1980. McBride-Kerr in [20] and Kerr in [14] provided integral expressions of the FRFT on $S(\mathbb{R})$ and $L^2(\mathbb{R})$, respectively. In [6], Chen, and the first, second and fourth authors of this paper, established the behavior of FRFT on $L^p(\mathbb{R})$ for $1 \leq p < 2$.

A chirp function is a nonstationary signal in which the frequency increases (upchirp) or decreases (downchirp) with time. The chirp signal is the most common nonstationary signal. In 1998, Zayed in [30] gave the following definition of the fractional Hilbert transform

$$
H_\alpha(f)(x) = \frac{1}{\pi} \text{ p.v.} e^{-\alpha(x)} \int_{\mathbb{R}} \frac{f(y)}{x - y} e_\alpha(y) dy,
$$

where $e_\alpha(x) = e^{\frac{\alpha x^2 \cot \alpha}{2}}$ is a chirp function.

In [23], Pei and Yeh expressed the discrete fractional Hilbert transform as a composition of the discrete fractional Fourier transform (DFRFT), a multiplier, and the inverse DFRFT; based on this they conducted simulation verification on the edge detection of digital images.
In [6], Chen, and the first, second and fourth authors of this paper related the fractional Hilbert transform to the fractional Fourier multiplier

\[ \mathcal{F}_\alpha(H_\alpha f)(x) = -\text{sgn}((\pi - \alpha)x)\mathcal{F}_\alpha(f)(x), \]

where \( \mathcal{F}_\alpha \) is FRFT; see Definition 1.2. In analogy with the Hilbert transform, the fractional Hilbert transform is also a phase-shift converter. As indicated above, the continuous fractional Hilbert transform can be decomposed into a composition of the FRFT, a multiplier, and the inverse FRFT. The fractional Hilbert transform can also be used in single sideband communication systems and image encryption systems. The rotation angle can be used as the encryption key to improve the communication security and image encryption effect in [28].

The multidimensional FRFT has recently made its appearance: Zayed [31, 32] introduced a new two-dimensional FRFT. In [15], Kamalakkannan and Roopkumar introduced the multidimensional FRFT.

**Definition 1.2.** ([15]) The multidimensional FRFT with order \( \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n) \) on \( L^1(\mathbb{R}^n) \) is defined by

\[ \mathcal{F}_\alpha(f)(u) = \int_{\mathbb{R}^n} f(x)K_\alpha(x, u)dx, \]

where \( K_\alpha(x, u) = \prod_{k=1}^n K_{\alpha_k}(x_k, u_k) \) and \( K_{\alpha_k}(x_k, u_k) \) are given by

\[ K_{\alpha_k}(x_k, u_k) = \begin{cases} \frac{c(\alpha_k)}{\sqrt{2\pi}}e^{i(a(\alpha_k)(x_k^2 + u_k^2 - 2b(\alpha_k)x_ku_k))}, & \alpha_k \notin \pi\mathbb{Z}, \\ \delta(x_k - u_k), & \alpha_k \in 2\pi\mathbb{Z}, \\ \delta(x_k + u_k), & \alpha_k \in 2\pi\mathbb{Z} + \pi, \end{cases} \]

\( x = (x_1, x_2, \ldots, x_n), \) \( a(\alpha_k) = \frac{\cot(\alpha_k)}{2}, b(\alpha_k) = \sec(\alpha_k), c(\alpha_k) = \sqrt{1 - i\cot(\alpha_k)}. \)

**Remark 1.2.** Suppose that \( \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{R}^n \) with \( \alpha_k \notin \pi\mathbb{Z} \) for all \( k = 1, 2, \ldots, n. \) Consider the chirps

\[ e_{\alpha}(x) = e^{i\sum_{k=1}^n a(\alpha_k)x_k^2}, \]

for \( x \in \mathbb{R}^n. \) It is straightforward to observe that FRFT of \( f \) can be written as

\[ \mathcal{F}_\alpha(f)(u) = c(\alpha)e_{\alpha}(u)\mathcal{F}(e_{\alpha}f)(\tilde{u}), \]

where \( c(\alpha) = c(\alpha_1) \cdots c(\alpha_n), \) \( \tilde{u} = (u_1 \csc \alpha_1, \ldots, u_n \csc \alpha_n). \) From the preceding identity, it can be seen that \( \mathcal{F}_\alpha \) is bounded from \( S(\mathbb{R}^n) \) to \( S(\mathbb{R}^n). \) We rewrite

\[ K_\alpha(x, u) = \frac{c(\alpha)}{(\sqrt{2\pi})^n}e_{\alpha}(x)e_{\alpha}(u)e^{-i\sum_{k=1}^n x_ku_k \csc \alpha_k}. \]

Motivated by this work, we define the fractional Riesz transform associated with the multidimensional FRFT as follows:

**Definition 1.3.** For \( 1 \leq j \leq n, \) the \( j \)th fractional Riesz transform of \( f \in S(\mathbb{R}^n) \) is given by

\[ R^\alpha_j(f)(x) = c_n \text{ p.v. } e_{-\alpha}(x) \int_{\mathbb{R}^n} \frac{x_j - y_j}{|x - y|^{n+1}} f(y)e_{\alpha}(y)dy, \]

where \( c_n = \Gamma\left(\frac{n+1}{2}\right)/\pi^{\frac{n+1}{2}} \) and \( \alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{R}^n \) with \( \alpha_k \notin \pi\mathbb{Z}, \) \( k = 1, 2, \ldots, n. \)
Remark 1.3. The fractional Riesz transform reduces to the fractional Hilbert transform for \( n = 1 \), while the fractional Riesz transform reduces to the classical Riesz transform for \( \alpha = (\frac{n}{2} + k_1 \pi, \frac{n}{2} + k_2 \pi, \ldots, \frac{n}{2} + k_n \pi) \), \( k_j \in \mathbb{Z} \), \( j = 1, 2, \ldots, m \).

This paper will be organized as follows. In Section 2, we obtain characterizations of the fractional Riesz transform in terms of the FRFT and we note that the fractional Riesz transform is not only a phase shift converter but also an amplitude attenuator. We obtain the identity \( \sum_{j=1}^{n}(R_j^{\alpha})^2 = -I \) and the boundedness of singular integral operators with a chirp function on rotation invariant spaces. In Section 3, we introduce the definition of the chirp Hardy space by taking the Possion maximum for the function with the chirp factor and study the dual spaces of chirp Hardy spaces. We also characterize the boundedness of singular integral operators with chirp functions on chirp Hardy spaces. In Section 4, we derive a formula for the high-dimensional FRFT and we provide an application of the fractional Riesz transform to partial differential equations. In Section 5, we conduct a simulation experiment with the fractional Riesz transform on an image and give the physical and geometric interpretation of the high-dimensional fractional multiplier theorem. In Section 6, we discuss a situation where it is difficult to directly use the fractional Riesz transform for edge detection but the fractional multiplier theorem provides this possibility. The use of the fractional Riesz transform is completely equivalent to the compound operation of the FRFT, inverse FRFT and multiplier, and the FRFT and inverse FRFT can realize fast operations.

2 Fractional Riesz transforms

2.1 Properties of the fractional Riesz transforms

Theorem 2.1. The \( j \)th fractional Riesz transform \( R_j^{\alpha} \) is given on the FRFT side by multiplication by the function \(-i \frac{\tilde{u}_j}{|u|}\). That is, for any \( f \in S(\mathbb{R}^n) \) we have

\[
\mathcal{F}_{\alpha}(R_j^{\alpha}f)(u) = -i \frac{\tilde{u}_j}{|u|} \mathcal{F}_{\alpha}(f)(u),
\]

where \( \alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{R}^n \) with \( \alpha_k \notin \pi \mathbb{Z} \), \( k = 1, 2, \ldots, n \); \( u = (u_1, \ldots, u_n) \) and \( \tilde{u} = (u_1 \csc \alpha_1, u_n \csc \alpha_n) = (\tilde{u}_1, \ldots, \tilde{u}_n) \).

Proof. Fix a \( f \in S(\mathbb{R}^n) \). For \( 1 \leq j \leq n \), we have

\[
\mathcal{F}_{\alpha}(R_j^{\alpha}f)(u) = \int_{\mathbb{R}^n} R_j^{\alpha}f(x) \frac{c(\alpha)}{(\sqrt{2\pi})^n} e_{\alpha}(x) e_{\alpha}(u) e^{i \sum_{j=1}^{n} x_j u_j \csc \alpha_j} dx
\]

\[
= \int_{\mathbb{R}^n} \frac{\Gamma(n+1)}{\pi^{\frac{n+1}{2}}} e^{-\alpha(x)} \lim_{\varepsilon \to 0} \int_{|y| \geq \varepsilon} \frac{y_j}{|y|^{n+1}} f(x-y) e_{\alpha}(x-y) dy
\]

\[
	imes \frac{c(\alpha)}{(\sqrt{2\pi})^n} e_{\alpha}(x) e_{\alpha}(u) e^{i \sum_{j=1}^{n} x_j u_j \csc \alpha_j} dx
\]

\[
= \frac{\Gamma(n+1)}{\pi^{\frac{n+1}{2}}} \lim_{\varepsilon \to 0} \int_{|y| \geq \varepsilon} \frac{y_j}{|y|^{n+1}} \int_{\mathbb{R}^n} f(x-y) e_{\alpha}(x-y) \frac{c(\alpha)}{(\sqrt{2\pi})^n} e_{\alpha}(u)
\]
\( \times e^{-i \sum_{j=1}^{n} x_j \csc \alpha_j} dxdy. \)

From the substitution of variables, we have

\[
\mathcal{F}_{\alpha}(R_j^\alpha f)(u) = \frac{\Gamma\left(\frac{n+1}{2}\right)}{\pi^{n/2}} \lim_{\varepsilon \to 0} \int_{|y| \geq \varepsilon} \frac{y_j}{|y|^{n+1}} \int_{\mathbb{R}^n} f(w) e_\alpha(w) \frac{c(\alpha)}{\sqrt{2\pi}} e_\alpha(u) \times e^{-i \sum_{j=1}^{n} (y_j + u_j) \csc \alpha_j} dwdy
\]

\[
= \frac{\Gamma\left(\frac{n+1}{2}\right)}{\pi^{n/2}} \lim_{\varepsilon \to 0} \int_{|y| \geq \varepsilon} \frac{y_j}{|y|^{n+1}} e^{-i \sum_{j=1}^{n} y_j u_j \csc \alpha_j} dy \int_{\mathbb{R}^n} \frac{c(\alpha)}{\sqrt{2\pi}} f(w) e_\alpha(u) e^{-i \sum_{j=1}^{n} u_j \csc \alpha_j} dw
\]

\[
= \frac{\Gamma\left(\frac{n+1}{2}\right)}{\pi^{n/2}} \mathcal{F}_\alpha(f)(u) \lim_{\varepsilon \to 0} \int_{|y| \geq \varepsilon} \frac{y_j}{|y|^{n+1}} e^{-i \sum_{j=1}^{n} y_j \csc \alpha_j} dy
\]

\[
= \frac{\Gamma\left(\frac{n+1}{2}\right)}{\pi^{n/2}} \mathcal{F}_\alpha(f)(u) \lim_{\varepsilon \to 0} \int_{|y| \leq \varepsilon} \frac{y_j}{|y|^{n+1}} e^{-i y \cdot \hat{u}} dy.
\]

Switching to polar coordinates and using Lemma 5.1.15 in [10], we obtain

\[
\mathcal{F}_{\alpha}(R_j^\alpha f)(u) = \frac{-i \Gamma\left(\frac{n+1}{2}\right)}{\pi^{n/2}} \mathcal{F}_\alpha(f)(u) \lim_{\varepsilon \to 0} \int_{s^{n-1}} \int_{r \leq \frac{1}{\varepsilon}} \sin(r \hat{u} \cdot \theta) \frac{r}{\sqrt{r \cdot w}} e^{-r \cdot w} dr d\theta
\]

\[
= \frac{-i \Gamma\left(\frac{n+1}{2}\right)}{2\pi^{n/2}} \mathcal{F}_\alpha(f)(u) \int_{s^{n-1}} \sin(\hat{u} \cdot \theta) d\theta
\]

\[
= \frac{-i \hat{u}_j}{|u|} \mathcal{F}_\alpha(f)(u),
\]

which completes the proof of the theorem. \(\square\)

**Lemma 2.2.** (*FRFT inversion theorem*) ([15]) Suppose \( f \in S(\mathbb{R}^n) \). Then

\[
f(x) = \int_{\mathbb{R}^n} \mathcal{F}_\alpha(f)(u) K_{-\alpha}(u, x) du, \quad a.e. \ x \in \mathbb{R}^n.
\]

By Theorem 2.1 and Lemma 2.2, the \( j \)th fractional Riesz transform of order \( \alpha \) can be rewritten as

\[
(R_j^\alpha f)(x) = \left[ \mathcal{F}_{-\alpha} \left( -i \frac{\hat{u}_j}{|u|} \mathcal{F}_\alpha f(u) \right) \right](x).
\]

Denote \( m_j^\alpha(u) := -i \hat{u}_j/|u| \). It can be seen that the fractional Riesz transform of a function \( f \) can be decomposed into three simpler operators, according to the diagram of Fig. 2.1:

(i) FRFT of order \( \alpha \), \( g(u) = (\mathcal{F}_\alpha f)(u) \);

(ii) multiplication by a fractional \( L^p \) multiplier, \( h(u) = m_j^\alpha(u)g(u) \);
(iii) FRFT of order $-\alpha$, $(R_j^\alpha f)(x) = (F_{-\alpha} h)(x)$

\[
\begin{array}{cccc}
f(x) & \xrightarrow{\mathcal{F}_\alpha} & g(u) & \xrightarrow{F_{-\alpha}} & (R_j^\alpha f)(x) \\
 & & m_j^\alpha(u) & & \\
\end{array}
\]

Figure 2.1: The decomposition of the $j$th fractional Riesz transform.

Take a 2-dimensional fractional Riesz transform as an example. It can be seen from Theorem 2.1 that the fractional Riesz transform of order $\alpha$ is a phase-shift converter that multiplies the positive portion in the $\alpha$-order fractional Fourier domain of signal $f$ by $-i$; in other words, it shifts the phase by $-\pi/2$ while the negative portion of $\mathcal{F}_\alpha f$ is shifted by $\pi/2$. It is also an amplitude reducer that multiplies the amplitude in the $\alpha$-order fractional Fourier domain of signal $f$ by $\tilde{u}_j/|\tilde{u}|$, as shown in Fig. 2.2.

Figure 2.2: (a) the original signal: $U = (\mathcal{F}_\alpha f)(u)$; (b) after fractional Riesz transform of order $\alpha$: $V = (\mathcal{F}_{\alpha}(R_j^\alpha f)(u))$; (c)-(d) rotations of the time-frequency planes, $u = (u_1, u_2)$, $x = (x_1, x_2)$, $\alpha = (\alpha_1, \alpha_2)$.

Next, we establish the $L^p(\mathbb{R}^n)$ boundedness of the fractional Riesz transform.
Theorem 2.3. For all \(1 < p < \infty\), there exists a positive constant \(C\) such that
\[
\|R_j^\alpha(f)\|_{L^p} \leq C\|f\|_{L^p},
\]
for all \(f\) in \(S(\mathbb{R}^n)\).

Proof. From the \(L^p\) boundedness of the Riesz transform in [19] with Theorem 2.1.4, it follows that
\[
\|R_j^\alpha(f)\|_{L^p} = \left( \int_{\mathbb{R}^n} \left| c_ne_{-\alpha}(x) \int_{\mathbb{R}^n} \frac{y_j}{|y|^{n+1}} f(x - y)e\alpha(x - y) dy \right|^p dx \right)^{\frac{1}{p}} \\
\leq C\|f\|_{L^p},
\]
for all \(f\) in \(S(\mathbb{R}^n)\). 

According to Theorem 2.1, we can obtain an identity property of the fractional Riesz transform.

Theorem 2.4. The fractional Riesz transforms satisfy
\[
\sum_{j=1}^{n} (R_j^\alpha)^2 = -I, \quad \text{on } L^2(\mathbb{R}^n),
\]
where \(I\) is the identity operator.

Proof. Use the FRFT and the identity \(\sum_{j=1}^{n} (-i\tilde{u}_j/|\tilde{u}|)^2 = -1\) to obtain
\[
\mathcal{F}_\alpha \left( \sum_{j=1}^{n} (R_j^\alpha)^2 f \right)(u) = \sum_{j=1}^{n} \left(-i\frac{\tilde{u}_j}{|\tilde{u}|}\right)^2 \mathcal{F}_\alpha(f)(u) \\
= -\mathcal{F}_\alpha(f)(u),
\]
for any \(f\) in \(L^2(\mathbb{R}^n)\). 

2.2 The boundedness of singular integral operators with chirp functions on rotation-invariant spaces

Just like the Riesz transforms, the fractional Riesz transforms are singular integral operators. They are special cases of more general singular integral operators whose kernels \(K\) are equipped with chirp functions
\[
T_\alpha(f)(x) = \text{p.v.} \int_{\mathbb{R}^n} e_{-\alpha}(x)K(x, y)e\alpha(y)f(y)dy = \text{p.v.} \int_{\mathbb{R}^n} K_\alpha(x, y)f(y)dy.
\]
When \(\alpha = (\frac{\pi}{2} + k_1\pi, \frac{\pi}{2} + k_2\pi, \ldots, \frac{\pi}{2} + k_n\pi), k_j \in \mathbb{Z}\), \(T_\alpha\) can be regarded as the classical singular integral operators:
\[
T(f)(x) = \text{p.v.} \int_{\mathbb{R}^n} K(x, y)f(y)dy.
\]
Then, we consider the boundedness of \(T_\alpha\) on rotation invariant Banach spaces.
Definition 2.5. Suppose that $(X, \| \cdot \|_X)$ is a Banach space. We call $X$ a rotation-invariant space if
\[ \| e_{\alpha} f \|_X = \| f \|_X, \]
for any $f \in X$, where $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{R}^n$ with $\alpha_k \notin \pi \mathbb{Z}$ for all $k = 1, 2, \ldots, n$.

When $K$ satisfies suitable conditions, the boundedness of $T_\alpha$ and $T$ in rotation invariant space is equivalent.

Theorem 2.6. If $X$ is a rotation invariant space, then $T$ is bounded from $X$ to $X$ if and only if $T_\alpha$ is bounded from $X$ to $X$.

Proof. Let $f \in X$ and $\| T \|_{X \to X} < \infty$. We have that
\[ \| T_\alpha(f) \|_X = \| T(e_\alpha f) \|_X \leq C \| e_\alpha f \|_X = C \| f \|_X. \]

Conversely, for $\| T_\alpha \|_{X \to X} < \infty$, we obtain
\[ \| T(f) \|_X = \| e_{-\alpha} T(f) \|_X = \| T_\alpha(e_{-\alpha} f) \|_X \leq C \| e_{-\alpha} f \|_X = C \| f \|_X. \]

Hence, the theorem follows. \( \square \)

3 Chirp Hardy spaces

In this section, we naturally consider the boundedness of a singular integral operator with a chirp function on non-rotation invariant space, such as Hardy spaces. Hardy spaces are spaces of distributions which become more singular as $p$ decreases and can be regarded as a substitute for $L^p$ when $p < 1$.

3.1 Chirp Hardy spaces and chirp BMO spaces

We recall the real variable characterization and atom characterization of Hardy spaces.

Definition 3.1. ([10]) Let $f$ be a bounded tempered distribution on $\mathbb{R}^n$ and let $0 < p < \infty$. We say that $f$ lies in the Hardy spaces $H^p(\mathbb{R}^n)$ if the Poisson maximal function
\[ M(f; P)(x) = \sup_{t > 0} |(P_t * f)(x)| \]
lies in $L^p(\mathbb{R}^n)$. If this is the case, we set
\[ \| f \|_{H^p} = \| M(f; P) \|_{L^p}. \]

Before introducing the atomic characterization of Hardy spaces, we recall the definition of atoms.

Definition 3.2. ([4, 17]) If $0 < p \leq 1 \leq q < \infty, p < q, s \in \mathbb{Z}$ and $s \geq \lfloor n(\frac{1}{p} - 1) \rfloor$, then $(p, q, s)$ satisfying the above conditions are said to be admissible triples, where $[\cdot]$ represents the greatest integer function. If the real valued function $a$ satisfies the following conditions:
(1) $a \in L^q(\mathbb{R}^n)$ and $\text{supp}(a) \subset Q$, where $Q$ is a cube centered on $x_0$;

(2) $\|a\|_{L^q} \leq |Q|^\frac{1}{q} - \frac{1}{p}$;

(3) $\int_{\mathbb{R}^n} a(x)x^\alpha dx = 0$, for any $|\alpha| \leq s$;

then $a$ is called the $(p, q, s)$-atom centered in $x_0$.

**Definition 3.3.** ([4, 17]) Suppose that $(p, q, s)$ are admissible triples. The atomic Hardy space $H_{\text{atom}}^{p,q,s}$ is

$$H_{\text{atom}}^{p,q,s}(\mathbb{R}^n) := \left\{ f \in S'(\mathbb{R}^n) : f(x) = \sum a_j(x), \text{ where } a_j \text{ is } (p, q, s)-\text{atom}, \right. $$

$$\left. \sum_{j=1}^{\infty} |\lambda_j|^p < \infty \right\},$$

and the norm in this space is defined by

$$\|f\|_{H_{\text{atom}}^{p,q,s}} := \inf \left( \sum_{j=1}^{\infty} |\lambda_j|^p \right)^{\frac{1}{p}}.$$

**Remark 3.1.** Suppose that $f \in S(\mathbb{R}^n)$. We have

$$\|f\|_{H^p} = \left\| \sup_{t>0} |P_t * f| \right\|_{L^p} = \left\| \sup_{t>0} \int_{\mathbb{R}^n} P_t(x-y)f(y)dy \right\|_{L^p},$$

$$\|e_\alpha f\|_{H^p} = \left\| \sup_{t>0} |P_t *(e_\alpha f)| \right\|_{L^p} = \left\| \sup_{t>0} \int_{\mathbb{R}^n} P_t(x-y)e_\alpha(y)f(y)dy \right\|_{L^p}.$$ 

We can clearly see that $\|e_\alpha f\|_{H^p}$ depends on $\alpha$, that is,

$$\|f\|_{H^p} \neq \|e_\alpha f\|_{H^p}.$$ 

Note that $H^p(\mathbb{R}^n)$ is not a rotation-invariant space.

Now let us consider the boundedness of singular integral operators with chirp functions in Hardy space when kernel $K$ satisfies certain size and smoothness conditions. Let us recall the definition of the $\delta$-Calderón-Zygmund operator.

**Definition 3.4.** ([18]) Let $T$ be a bounded linear operator. We say that $T$ is a $\delta$-Calderón-Zygmund operator if $T$ is bounded on $L^2(\mathbb{R}^n)$ and $K$ is a continuous function on $\mathbb{R}^n \times \mathbb{R}^n \setminus \{(x, y) : x \neq y\}$ that satisfies

(1) $|K(x, y)| \leq \frac{C}{|x-y|^{\pi}}, \; x \neq y;$
(2) \(|K(x, y) - K(x, z)| + |K(y, x) - K(z, x)| \leq C \frac{|y - z|^d}{|x - z|^{d + \varepsilon}}, \) if \(|x - z| > 2|y - z|, 0 < \delta \leq 1;\)

(3) For \(f, g \in S(R^n)\) and \(\text{supp } f \cap \text{supp } g = \emptyset,\) one has \((Tf, g) = \int K(x, y) f(y) g(x) dy dx.\)

Lemma 3.5. ([18]) Suppose that \(T\) is a \(\delta\)-Calderón-Zygmund operator and its conjugate operator \(T^* = 0.\) Then, \(T\) can be extended to the bounded operator from \(H^p(R^n)\) to \(H^p(R^n),\) where \(0 < \delta \leq 1\) and \(\frac{n}{n+\delta} < p \leq 1.\)

By standard calculations, we have the following estimates for \(K^\alpha:\)

\[|K^\alpha(x, y) - K^\alpha(x, z)| \leq |K(x, y) - K(x, z)| + L_\alpha(y, z)|K(x, z)||y - z|,\]

where \(L_\alpha(y, z) = |\nabla e_\alpha(w)| = \sqrt{n \sum_{k=1}^{n} |e_\alpha(w)\cot \alpha_k w_k|^2},\)
and \(w = z + (\theta_1(y_1 - z_1), \ldots, \theta_n(y_n - z_n))\) for \(\theta_j \in (0, 1).\) It is known that for \(\alpha = (\frac{\pi}{2} + k_1\pi, \frac{\pi}{2} + k_2\pi, \ldots, \frac{\pi}{2} + k_n\pi),\) \(K^\alpha\) satisfies the \(\delta\)-Calderón-Zygmund operator kernel condition (2). It is obvious that \(K^\alpha\) satisfies (1) in Definition 3.4, but (2) in Definition 3.4 is not guaranteed.

We now define a new class of Hardy space with chirp functions.

Definition 3.6. Let \(f\) be a bounded tempered distribution on \(R^n\) and let \(0 < p < \infty.\) We say that \(f\) lies in the chirp Hardy space \(H^p_{\alpha}(R^n)\) for \(\alpha = (\alpha_1, \ldots, \alpha_n) \in R^n\) with \(\alpha_k \not\in \pi Z\) for all \(k = 1, 2, \ldots, n\), if the Poisson maximal function with chirp function

\[M_\alpha(f; P) = \sup_{t > 0} ||(P_t \ast (e_\alpha f))||\]

lies in \(L^p(R^n).\) If this is the case, we set

\[||f||_{H^p_{\alpha}} = ||M_\alpha(f; P)||_{L^p}.\]

Lemma 3.7. ([11]) The Hardy space \(H^p_{\alpha}(R^n)\) is a complete space.

Theorem 3.8. The chirp Hardy space \(H^p_{\alpha}(R^n)\) is a complete space.

Proof. Let \(\{f_k\}\) be a Cauchy sequence in \(H^p_{\alpha}(R^n).\) Then, \(\{e_\alpha f_k\}\) is a Cauchy sequence in \(H^p(R^n).\) By Lemma 3.7, there exists an \(\tilde{f} \in H^p(R^n)\) such that

\[\lim_{k \to \infty} ||e_\alpha f_k - \tilde{f}||_{H^p} = 0.\]

The above identity is rewritten as

\[\lim_{k \to \infty} ||f_k - e_{-\alpha} \tilde{f}||_{H^p_{\alpha}} = 0.\]

Since \(\tilde{f} \in H^p(R^n),\) we obtain \(f := e_{-\alpha} \tilde{f} \in H^p_{\alpha}(R^n),\) which completes the proof of the theorem. \(\Box\)
It is known that the dual space of $H^1$ is the $BMO$ space. To study the dual space of the chirp Hardy space, we define a new $BMO$ space with a chirp function as follows.

**Definition 3.9.** Suppose that $f$ is a locally integrable function on $\mathbb{R}^n$. Define the chirp $BMO$ space as

$$BMO^\alpha(\mathbb{R}^n) = \{ f : \| f \|_{BMO^\alpha} < \infty \}.$$

Let

$$\| f \|_{BMO^\alpha} = \sup_Q \frac{1}{|Q|} \int_Q |e_\alpha(x)f(x) - \text{Avg}_Q(e_\alpha f)|dx,$$

where the supremum is taken over all cubes $Q$ in $\mathbb{R}^n$ and $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{R}^n$ with $\alpha_k \notin \pi\mathbb{Z}$, $k = 1, 2, \ldots, n$.

**Lemma 3.10.** ([7, 11]) $BMO$ is a complete space.

**Theorem 3.11.** $BMO^\alpha$ is complete.

The proof follows the same pattern as that of Theorem 3.8 and is based on Lemma 3.10.

### 3.2 Dual spaces of chirp Hardy spaces

Let $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{R}^n$ with $\alpha_k \notin \pi\mathbb{Z}$ for all $k = 1, 2, \ldots, n$. We discuss the dual spaces of chirp Hardy spaces $H^p_\alpha(\mathbb{R}^n)$ for $0 < p \leq 1$. When $p = 1$, we have the following theorem.

**Theorem 3.12.** $(H^1_\alpha)^*(\mathbb{R}^n) = BMO^{-\alpha}(\mathbb{R}^n)$. That is,

1. For any $g \in BMO^{-\alpha}(\mathbb{R}^n)$,

   $$L(f) := \int_{\mathbb{R}^n} f(x)g(x)dx$$

   is a bounded linear functional on $H^1_\alpha(\mathbb{R}^n)$ and $\| L \| \leq C\| g \|_{BMO^{-\alpha}}$.

2. For any bounded linear functionals $L$ defined on $H^1_\alpha(\mathbb{R}^n)$, there exists a $g \in BMO^{-\alpha}(\mathbb{R}^n)$ such that

   $$L(f) := \int_{\mathbb{R}^n} f(x)g(x)dx,$$

   for any $f \in H^1_\alpha(\mathbb{R}^n)$, $\| g \|_{BMO^{-\alpha}} \leq C\| L \|$.

Before proving the theorem, we need to recall some known results.

**Lemma 3.13.** ([17]) For all $1 \leq q \leq \infty$, it follows that $H^{p,q,s}_{atom}(\mathbb{R}^n) = H^p(\mathbb{R}^n)$ and $\| f \|_{H^{p,q,s}_{atom}} \approx \| f \|_{H^p}$ for $f \in H^p(\mathbb{R}^n)$.

**Lemma 3.14.** ([7], [8], [9]) $(H^1)^*(\mathbb{R}^n) = BMO(\mathbb{R}^n)$.

Now, we will go back to prove Theorem 3.12.
Lemma 3.15. Hence, $\tilde{L} \in f$ exists a unique polynomial where $g$ is (1, $\infty$, 0)-atom. Suppose that $g \in BMO^{-\alpha}(\mathbb{R}^n)$. We have

$$|L(f)| = \left| \int_{\mathbb{R}^n} f(x)g(x)dx \right|$$

$$= \left| \int_{\mathbb{R}^n} e_{-\alpha}(x) \sum_{j=1}^{\infty} \lambda_j a_j(x)g(x)dx \right|$$

$$= \sum_{j=1}^{\infty} \lambda_j \int_{Q_j} a_j(x)[e_{-\alpha}(x)g(x) - (e_{-\alpha}g)Q]dx$$

$$\leq \sum_{j=1}^{\infty} |\lambda_j| \frac{1}{|Q_j|} \int_{Q_j} |e_{-\alpha}(x)g(x) - (e_{-\alpha}g)Q|dx$$

$$\leq C \sum_{j=1}^{\infty} |\lambda_j| \|g\|_{BMO^{-\alpha}}$$

$$= C \|e_{-\alpha}f\|_{H_1^1} \|g\|_{BMO^{-\alpha}}$$

$$= C \|f\|_{H_1^1} \|g\|_{BMO^{-\alpha}}.$$ 

Then L is a bounded linear functional on $H_1^\alpha(\mathbb{R}^n)$ and $\|L\| \leq C \|g\|_{BMO^{-\alpha}}$.

Now given an $L \in (H_1^\alpha)^*(\mathbb{R}^n)$, denote $\tilde{L}(f) := L(e_{-\alpha}f)$ for any $f \in H_1^1(\mathbb{R}^n)$. We have

$$|\tilde{L}(f)| = |L(e_{-\alpha}f)| \leq \|L\| \|e_{-\alpha}f\|_{H_1^1} = \|L\| \|f\|_{H_1^1}.$$ 

Hence, $\tilde{L} \in (H_1^1)^*(\mathbb{R}^n)$ and $\|\tilde{L}\| \leq \|L\|$.

From Lemma 3.14, $\tilde{g} \in BMO(\mathbb{R}^n)$ exists such that $\tilde{L}(f) = \int_{\mathbb{R}^n} f(x)\tilde{g}(x)dx$ for any $f \in H_1^1(\mathbb{R}^n)$ and $\|\tilde{g}\|_{BMO} \leq C \|\tilde{L}\|$.

For any $f \in H_1^\alpha(\mathbb{R}^n)$, $e_{\alpha}f \in H_1^1(\mathbb{R}^n)$. We obtain

$$L(f) = \tilde{L}(e_{\alpha}f) = \int_{\mathbb{R}^n} e_{\alpha}(x)f(x)\tilde{g}(x)dx = \int_{\mathbb{R}^n} f(x)g(x)dx,$$

where $g = e_{\alpha}\tilde{g}$. Since $\tilde{g} \in BMO(\mathbb{R}^n)$ and $\|\tilde{g}\|_{BMO} \leq C \|\tilde{L}\|$, $g \in BMO^{-\alpha}(\mathbb{R}^n)$ and $\|g\|_{BMO^{-\alpha}} = \|\tilde{g}\|_{BMO} \leq C \|\tilde{L}\| \leq C \|L\|$, which completes the proof of the theorem. \qed

**Remark 3.2.** When $\alpha = (\frac{1}{2} + k_1 \pi, \frac{1}{2} + k_2 \pi, \ldots, \frac{1}{2} + k_m \pi), k_j \in \mathbb{Z}$ for $j = 1, 2, \ldots, m$, $(H_1^\alpha)^*(\mathbb{R}^n) = BMO^{-\alpha}(\mathbb{R}^n)$ reduces to $(H_1^1)^*(\mathbb{R}^n) = BMO(\mathbb{R}^n)$.

Now let us proceed to consider the dual space of the chirp Hardy space when $0 < p < 1$.

**Lemma 3.15.** ([25]) For $g \in L_1^{1,\infty}(\mathbb{R}^n)$, $Q$ is any cube in $\mathbb{R}^n$ and $s \in \mathbb{Z}^+$. Then there exists a unique polynomial $P_Q(g)$ whose degree does not exceed $s$ that satisfies

$$\int_Q |g(x) - P_Q(g)(x)|x^sdx = 0, \quad 0 \leq |\alpha| \leq s.$$
Definition 3.16. ([25]) For $s \in \mathbb{Z}^+$, $0 \leq |n\beta| \leq s$ and $1 \leq q' \leq \infty$, the Campanato-Meyers space $L(\beta, q', s)(\mathbb{R}^n)$ is defined as the set of locally integrable functions $g$ that satisfy

$$\|g\|_{L(\beta, q', s)} = \sup_{Q \subset \mathbb{R}^n} |Q|^{-\beta} \left[ \int_Q |g(x) - P_Q(g)(x)|^{q'} \frac{dx}{|Q|} \right]^\frac{1}{q'} < \infty,$$

where $P_Q(g)$ is determined by Lemma 3.15.

Lemma 3.17. ([9, 22]) $(H^p)^*(\mathbb{R}^n) = L(\frac{1}{p}, q', s)(\mathbb{R}^n)$, where $0 < p < 1 \leq q \leq \infty$, $s \in \mathbb{Z}$, $s \geq n(\frac{1}{p} - 1)$ and $1/q + 1/q' = 1$.

Now let us define a new Campanato-Meyers space with chirps as follows:

Definition 3.18. For $s \in \mathbb{Z}^+$, $0 \leq |n\beta| \leq s$ and $1 \leq q' \leq \infty$. The chirp Campanato-Meyers space $L_{\alpha}(\beta, q', s)(\mathbb{R}^n)$ is defined as the set of locally integrable functions $g$ that satisfy

$$\|g\|_{L_{\alpha}(\beta, q', s)} = \sup_{Q \subset \mathbb{R}^n} |Q|^{-\beta} \left[ \int_Q |e_{\alpha}(x)g(x) - P_Q(e_{\alpha}g)(x)|^{q'} \frac{dx}{|Q|} \right]^\frac{1}{q'} < \infty,$$

where $P_Q(e_{\alpha}g)$ is determined by Lemma 3.15.

Theorem 3.19. $(H^p_{\alpha})^*(\mathbb{R}^n) = L_{-\alpha}(\frac{1}{p}, q', s)(\mathbb{R}^n)$, where $0 < p < 1 \leq q \leq \infty$, $s \in \mathbb{Z}$, $s \geq n(\frac{1}{p} - 1)$ and $1/q + 1/q' = 1$.

Proof. For any $f \in H^p_{\alpha}(\mathbb{R}^n)$, by Lemma 3.13, we have $e_{\alpha}f \in H^p(\mathbb{R}^n)$ such that $e_{\alpha}f = \sum_{j=1}^\infty \lambda_j a_j$, where $a_j$ is a $(p, q, s)$-atom. Suppose that $g \in L_{-\alpha}(\frac{1}{p}, q', s)(\mathbb{R}^n)$. We have

$$|L(f)| = \left| \int_{\mathbb{R}^n} e_{-\alpha}(x) \sum_{j=1}^\infty \lambda_j a_j(x)g(x)dx \right|$$

$$= \left| \sum_{j=1}^\infty \lambda_j \int_{Q_j} a_j(x)[e_{-\alpha}(x)g(x) - P_{Q_j}(e_{-\alpha}(x)g(x))]dx \right|$$

$$\leq \sum_{j=1}^\infty |\lambda_j| \|a_j\|_{L^q} \left( \int_{Q_j} |e_{-\alpha}(x)g(x) - P_{Q_j}(e_{-\alpha}(x)g(x))|^{q'} dx \right)^\frac{1}{q'}$$

$$\leq C \left( \sum_{j=1}^\infty |\lambda_j|^p \right)^\frac{1}{p} \|g\|_{L_{-\alpha}(\frac{1}{p}, q', s)} \|f\|_{H^p_{\alpha}}$$

Then $L$ is a bounded linear functional on $H^p_{\alpha}(\mathbb{R}^n)$ and $\|L\| \leq C\|g\|_{L_{-\alpha}(\frac{1}{p}, q', s)}$.

Given $L \in (H^p_{\alpha})^*(\mathbb{R}^n)$, denote $\tilde{L}(f) := L(e_{-\alpha}f)$ for any $f \in H^p(\mathbb{R}^n)$. We have

$$|\tilde{L}(f)| = |L(e_{-\alpha}f)| \leq \|L\| \|e_{-\alpha}f\|_{H^p_{\alpha}} = \|L\| \|f\|_{H^p}.$$
Hence, \( \hat{L} \in (H^p)^\ast (\mathbb{R}^n) \) and \( \| \hat{L} \| \leq \| L \| \).

By Lemma 3.17, there exists \( \hat{g} \in L(\frac{1}{p}, q', s)(\mathbb{R}^n) \) such that \( \hat{L}(f) = \int_{\mathbb{R}^n} f(x)\hat{g}(x)dx \) for any \( f \in H^p(\mathbb{R}^n) \) and \( \| \hat{g} \|_{L_\alpha(\frac{1}{p}, q', s)} \leq C\| \hat{L} \| \).

For any \( f \in H^p_\alpha(\mathbb{R}^n) \), \( e_\alpha f \in H^p(\mathbb{R}^n) \). We obtain

\[
L(f) = \hat{L}(e_\alpha f) = \int_{\mathbb{R}^n} e_\alpha(x)f(x)\hat{g}(x)dx = \int_{\mathbb{R}^n} f(x)g(x)dx,
\]

where \( g = e_\alpha \hat{g} \). Since \( \hat{g} \in L(\frac{1}{p}, q', s)(\mathbb{R}^n) \) and \( \| \hat{g} \|_{L(\frac{1}{p}, q', s)} \leq C\| \hat{L} \| \), then \( g \in L-\alpha(\frac{1}{p}, q', s) \) and \( \| g \|_{L-\alpha(\frac{1}{p}, q', s)} = \| \hat{g} \|_{L(\frac{1}{p}, q', s)} \leq C\| \hat{L} \| \leq C\| L \| \), which completes the proof of the theorem. \( \square \)

**Remark 3.3.** When \( 0 < p < 1 \) and \( \alpha = \left( \frac{\pi}{2} + k_1\pi, \frac{\pi}{2} + k_2\pi, \ldots, \frac{\pi}{2} + k_n\pi \right), k_j \in \mathbb{Z} \) for \( j = 1, 2, \ldots, m, (H^p_\alpha)^\ast (\mathbb{R}^n) = L-\alpha(\frac{1}{p}, q', s)(\mathbb{R}^n) \) reduces to \((H^p)^\ast (\mathbb{R}^n) = L(\frac{1}{p}, q', s)(\mathbb{R}^n)\).

### 3.3 Characterization of the boundedness of singular integral operators with chirp functions on chirp Hardy spaces

In this subsection we obtain a characterization of the boundedness of \( T_\alpha \) in \( H^p_\alpha \).

**Theorem 3.20.** \( T_\alpha \) is bounded from \( H^p_\alpha(\mathbb{R}^n) \) to \( H^p_\alpha(\mathbb{R}^n) \) if and only if \( T \) is bounded from \( H^p(\mathbb{R}^n) \) to \( H^p(\mathbb{R}^n) \), where \( \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{R}^n \) with \( \alpha_k \notin \pi\mathbb{Z} \).

**Proof.** Suppose that \( f \in S' \) and \( \| T_\alpha \|_{H^p_\alpha \to H^p_\alpha} < \infty \). Then, we have

\[
\| T(f) \|_{H^p} = \left\| \sup_{t > 0} |P_t * (e_\alpha (e_{-\alpha} T f))| \right\|_{L^p} = \| T_\alpha (e_{-\alpha} f) \|_{H^p_\alpha} \leq C\| e_{-\alpha} f \|_{H^p_\alpha} = C\| f \|_{H^p}.
\]

Conversely, when \( \| T \|_{H^p \to H^p} < \infty \), we obtain

\[
\| T_\alpha (f) \|_{H^p_\alpha} = \left\| \sup_{t > 0} |P_t * (T(e_\alpha f))| \right\|_{L^p} = \| T(e_\alpha f) \|_{H^p} \leq C\| e_\alpha f \|_{H^p} = C\| f \|_{H^p}.
\]

Hence, the theorem follows. \( \square \)

### 4 Application of the fractional Riesz transform in partial differential equations

The fractional Riesz transforms can be used to reconcile various combinations of partial derivatives of functions. We first established the derivative formula of the FRFT.
Lemma 4.1. (FRFT derivative formula) Suppose that $f \in L^1(\mathbb{R}^n)$. If $e_{\alpha}f$ is absolutely continuous on $\mathbb{R}^n$ with respect to the $k$th variable, we have

$$
\mathcal{F}_\alpha \left( e_{-\alpha}(y) \frac{\partial [e_{\alpha}(y)f(y)]}{\partial y_k} \right)(x) = ix_k \csc \alpha_k \mathcal{F}_\alpha(f)(x),
$$

where $x = (x_1, x_2, \ldots, x_n)$ and $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{R}^n$ with $\alpha_k \notin \pi \mathbb{Z}$, $k = 1, 2, \ldots, n$.

Proof. Since $e_{\alpha}f$ is absolutely continuous on $\mathbb{R}^n$ with respect to the $k$th variable, we can get that $\frac{\partial [e_{\alpha}(y)f(y)]}{\partial y_k} \in L^1(\mathbb{R}^n)$. For $f \in L^1(\mathbb{R}^n)$, we have

$$
\mathcal{F}_\alpha \left( e_{-\alpha}(y) \frac{\partial [e_{\alpha}(y)f(y)]}{\partial y_k} \right)(x) = \frac{c(\alpha)}{(\sqrt{2\pi})^n} \int_{\mathbb{R}^n} \left( e_{-\alpha}(y) \frac{\partial [e_{\alpha}(y)f(y)]}{\partial y_k} \right) e_\alpha(y) \times e_\alpha(x) e^{-i \sum_{j=1}^{n} x_j y_j \csc \alpha_j} dy_k
$$

$$
= \frac{c(\alpha)}{(\sqrt{2\pi})^n} e_\alpha(x) \int_{\mathbb{R}^n} \frac{\partial [e_{\alpha}(y)f(y)]}{\partial y_k} e^{-i \sum_{j=1}^{n} x_j y_j \csc \alpha_j} dy_k
$$

$$
= \frac{c(\alpha) e_\alpha(x)}{(\sqrt{2\pi})^n} \int_{\mathbb{R}^{n-1}} \int_{\mathbb{R}} \frac{\partial [e_{\alpha}(y)f(y)]}{\partial y_k} e^{-ix_k y_k \csc \alpha_k} dy_k
$$

$$
\times \prod_{j=1,j \neq k}^{n} e^{-ix_j y_j \csc \alpha_j} \int_{\mathbb{R}} dy_k.
$$

As $e_{\alpha}f$ is absolutely continuous on $\mathbb{R}^n$ with respect to the $k$th variable, an integration by parts yields

$$
\int_{\mathbb{R}} \frac{\partial [e_{\alpha}(y)f(y)]}{\partial y_k} e^{-ix_k y_k \csc \alpha_k} dy_k = ix_k \csc \alpha_k \int_{\mathbb{R}} e_{\alpha}(y)f(y) e^{-ix_k y_k \csc \alpha_k} dy_k.
$$

Then

$$
\mathcal{F}_\alpha \left( e_{-\alpha}(y) \frac{\partial [e_{\alpha}(y)f(y)]}{\partial y_k} \right)(x) = ix_k \csc \alpha_k \frac{c(\alpha)}{(\sqrt{2\pi})^n} \int_{\mathbb{R}^n} e_\alpha(y)f(y) e_\alpha(x) e^{-i \sum_{j=1}^{n} x_j y_j \csc \alpha_j} dy_k
$$

$$
= ix_k \csc \alpha_k \mathcal{F}_\alpha(f)(x),
$$

which completes the proof of the lemma. \qed

Lemma 4.2. (FRFT derivative formula) Suppose that $f \in L^1(\mathbb{R}^n)$ and $x_k f(x) \in L^1(\mathbb{R}^n)$. Then, we have

$$
\frac{\partial (e_{-\alpha}(x) \mathcal{F}_\alpha(f)(x))}{\partial x_k} = e_{-\alpha}(x) \mathcal{F}_\alpha(-iy_k \csc \alpha_k f(y))(x),
$$

for $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{R}^n$ with $\alpha_k \notin \pi \mathbb{Z}$, $k = 1, 2, \ldots, n$.

Proof. Let $\Delta_k = (0, \ldots, 0, \delta, 0, \ldots, 0)$, $\delta \neq 0$, and let $\delta$ be the $k$th variable. Then

$$
\frac{\partial (e_{-\alpha}(x) \mathcal{F}_\alpha(f)(x))}{\partial x_k} = \lim_{\delta \to 0} \frac{e_{-\alpha}(x + \Delta k) \mathcal{F}_\alpha(f)(x + \Delta k) - e_{-\alpha}(x) \mathcal{F}_\alpha(f)(x)}{\delta}
$$
Suppose that

\[ \text{Theorem 4.3.} \]

4.1 Application in the a priori bound estimates of partial differential equations

Taking the FRFT of the above identity, we have

\[ \text{Proof.} \]

\[
\frac{1}{\delta} \left( \int_{\mathbb{R}^n} \frac{c(\alpha)}{(\sqrt{2\pi})^n} f(y)e^{\alpha}(y)e^{-i(x+\Delta k)\cdot \hat{y}} dy - \int_{\mathbb{R}^n} \frac{c(\alpha)}{(\sqrt{2\pi})^n} f(y)e^{\alpha}(y)e^{-ix\cdot \hat{y}} dy \right)
\]

\[
= \frac{1}{\delta} \left( \int_{\mathbb{R}^n} \frac{c(\alpha)}{(\sqrt{2\pi})^n} f(y)e^{\alpha}(y)e^{-i\cdot \hat{y}(e^{-i\delta\hat{y}} - 1)} dy \right).
\]

By \(|e^{-i\delta\hat{y}}| \leq 2\pi|\hat{y}|\), \(x_kf(x) \in L^1(\mathbb{R}^n)\) and the Lebesgue dominated convergence theorem we write

\[
\frac{\partial(e_{-\alpha}(x)f_{\alpha}(f))}{\partial x_k} = \int_{\mathbb{R}^n} \frac{c(\alpha)}{(\sqrt{2\pi})^n} f(y)e^{\alpha}(y)e^{-i\cdot \hat{y}\left(\lim_{\delta \to 0} \frac{1}{\delta}(e^{-i\delta\hat{y}} - 1)\right)} dy
\]

\[
= \int_{\mathbb{R}^n} \frac{c(\alpha)}{(\sqrt{2\pi})^n} f(y)e^{\alpha}(y)e^{-i\hat{y}(-i\hat{y})} dy
\]

\[
= e_{-\alpha}(x)f_{\alpha}(-i\hat{y} \csc \alpha_k f(y))(x),
\]

where \(\hat{y} = (\hat{y}_1, \ldots, \hat{y}_n) = (y_1 \csc \alpha_1, \ldots, y_n \csc \alpha_n).\)

\[\Box\]

4.1 Application in the a priori bound estimates of partial differential equations

We will next introduce the applications of \(R^\alpha\) in the priori bound estimates.

\[\text{Theorem 4.3. Suppose that } f \in S(\mathbb{R}^2). \text{ Then, we have the a priori bound} \]

\[
\| \frac{\partial(e_{\alpha}f)}{\partial y_1} \|_p + \| \frac{\partial(e_{\alpha}f)}{\partial y_2} \|_p \leq C \| e_{-\alpha}(y) \frac{\partial(e_{\alpha}(y)f(y))}{\partial y_1} + ie_{\alpha}(y) \frac{\partial(e_{\alpha}(y)f(y))}{\partial y_2} \|_p, \quad 1 < p < \infty,
\]

where \(\alpha = (\alpha_1, \alpha_2) \in \mathbb{R}^2\) with \(\alpha_k \notin \pi\mathbb{Z}, \ k = 1, 2.\)

To prove Theorem 4.3, we need the following lemma.

\[\text{Lemma 4.4. Let } f \in S(\mathbb{R}^2). \text{ We have} \]

\[
e_{-\alpha}(y) \frac{\partial(e_{\alpha}(y)f(y))}{\partial y_j} = -R_j^\alpha(R_1^\alpha - iR_2^\alpha) \left( e_{-\alpha}(y) \frac{\partial(e_{\alpha}(y)f(y))}{\partial y_1} + ie_{\alpha}(y) \frac{\partial(e_{\alpha}(y)f(y))}{\partial y_2} \right),
\]

for \(j = 1, 2\) and \(\alpha = (\alpha_1, \alpha_2) \in \mathbb{R}^2\) with \(\alpha_k \notin \pi\mathbb{Z}, k = 1, 2.\)

\[\text{Proof. Taking the FRFT of the above identity, we have} \]

\[
\mathcal{F}_\alpha \left( -R_j^\alpha(R_1^\alpha - iR_2^\alpha) \left( e_{-\alpha}(y) \frac{\partial(e_{\alpha}(y)f(y))}{\partial y_1} + ie_{\alpha}(y) \frac{\partial(e_{\alpha}(y)f(y))}{\partial y_2} \right) \right)(x)
\]

\[
= -\frac{i\bar{x}_j}{|x|} \left( i\bar{x}_1 + i\bar{x}_2 \right) \left( i\alpha_1 \csc \alpha_1 \mathcal{F}_\alpha(f)(x) - x_2 \csc \alpha_2 \mathcal{F}_\alpha(f)(x) \right).
\]
Lemma 4.5. For Theorem 4.3 simplifies to Proposition 4 in [24, pp.60].

Remark 4.1. When \( \alpha = (\frac{\pi}{2} + k_1 \pi, \frac{\pi}{2} + k_2 \pi, \ldots, \frac{\pi}{2} + k_n \pi), k_j \in \mathbb{Z} \) for \( j = 1, 2, \ldots, m \), Theorem 4.3 simplifies to Proposition 4 in [24, pp.60].

Lemma 4.5. For \( f \in S(\mathbb{R}^n) \) and \( 1 \leq j, k \leq n \), we have

\[
\frac{\partial(e_\alpha f)}{\partial y_j} = -R_1^\alpha (R_j^\alpha - i R_2^\alpha) \left( e_\alpha(y) \frac{\partial(e_\alpha f(y))}{\partial y_1} + ie_\alpha(y) \frac{\partial(e_\alpha f(y))}{\partial y_2} \right)
\]

which completes the proof of the theorem. \( \square \)

Proof. By Lemma 4.1 and Theorem 2.3, we have

\[
\left\| \frac{\partial(e_\alpha f)}{\partial y_j} \right\|_{L^p} \leq C \left\| e_\alpha(y) \frac{\partial(e_\alpha f(y))}{\partial y_1} + ie_\alpha(y) \frac{\partial(e_\alpha f(y))}{\partial y_2} \right\|_{L^p},
\]

for all \( y \in \mathbb{R}^n \), where \( \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{R}^n \) with \( \alpha_k \notin \pi \mathbb{Z} \).

Proof. Taking the FRFT of the above identity, we have

\[
\mathcal{F}_\alpha \left( e_\alpha(y) \frac{\partial^2(e_\alpha f(y))}{\partial y_k \partial y_j} \right)(x) = \mathcal{F}_\alpha \left( e_\alpha(y) \frac{\partial}{\partial y_k} \left( e_\alpha(y) \frac{\partial(e_\alpha f(y))}{\partial y_j} \right) \right)(x)
\]

By Lemma 4.1, we have

\[
\mathcal{F}_\alpha \left( e_\alpha(y) \frac{\partial(e_\alpha f(y))}{\partial y_j} \right)(x) = ix_j \csc \alpha_j \mathcal{F}_\alpha(f(x)).
\]

Applying the inverse FRFT on the above identity we deduce the desired result. \( \square \)
\[ F_{\alpha}(-R_j^\alpha R_k^\alpha e^{-\alpha} \Delta(e_{\alpha} f))(x). \]

Applying the inverse FRFT on the above identity, we obtain the desired result. \( \square \)

**Remark 4.2.** When \( \alpha = (\frac{\pi}{2} + k_1\pi, \frac{\pi}{2} + k_2\pi, \ldots, \frac{\pi}{2} + k_n\pi), k_j \in \mathbb{Z} \) for \( j = 1, 2, \ldots, m \), Lemma 4.5 can be simplified to Proposition 5.1.17 in [10].

**Theorem 4.6.** Suppose \( f \in S(R^n) \) and \( \Delta(e_{\alpha} f) = \sum_{j=1}^{n} \frac{\partial^2(e_{\alpha} f)}{\partial y_k \partial y_j} \). Then we have a priori bound

\[ \left\| \frac{\partial^2(e_{\alpha} f)}{\partial y_k \partial y_j} \right\|_{L^p} \leq C \left\| \Delta(e_{\alpha} f) \right\|_{L^p}, \]

for \( \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{R}^n \) with \( \alpha_k \notin \pi \mathbb{Z}, k = 1, 2, \ldots, n \).

**Proof.** According to Lemma 4.5 and Theorem 2.3, we obtain that

\[ \left\| \frac{\partial^2(e_{\alpha} f)}{\partial y_k \partial y_j} \right\|_{L^p} = \left\| e^{-\alpha} \frac{\partial^2(e_{\alpha} f)}{\partial y_k \partial y_j} \right\|_{L^p} = \left\| -R_j^\alpha R_k^\alpha e^{-\alpha} \Delta(e_{\alpha} f) \right\|_{L^p} \leq C \left\| \Delta(e_{\alpha} f) \right\|_{L^p}, \]

which completes the proof of the theorem. \( \square \)

### 4.2 A characterization of Laplace’s equation

Next we give a characterization of Laplace’s equation.

**Example 4.1.** Suppose that \( u \in S'(\mathbb{R}^n) \) and \( f \in L^2(\mathbb{R}^n) \). We solve Laplace’s equation

\[ \Delta(e_{\alpha} u) = e_{\alpha} f. \]  \( \text{(4.1)} \)

One of the methods can be found in [6]. In this paper, we express all second-order derivatives of \( u \) in terms of the fractional Riesz transform of \( f \). In order to accomplish this we provide a necessary lemma.

**Lemma 4.7.** ([10]) Suppose that \( u \in S'(\mathbb{R}^n) \). If \( \hat{u} \) is supported at \( \{0\} \), then \( u \) is a polynomial.

To solve equation (4.1), we first show that the tempered distribution

\[ \mathcal{F}_{\alpha}(e_{-\alpha} \partial_j \partial_k(e_{\alpha} u) + R_j^\alpha R_k^\alpha f) \]

is supported at \( \{0\} \). From Lemma 4.7, we can obtain that

\[ e_{-\alpha} \partial_j \partial_k(e_{\alpha} u) = -R_j^\alpha R_k^\alpha f + e_{\alpha} P, \]

where \( P \) is a polynomial of \( n \) variables (that depends on \( j \) and \( k \)). Then we provide a method of expressing mixed partial derivatives of \( e_{\alpha} u \) in terms of the fractional Riesz transform of \( f \).
To prove that the tempered distribution \( F_\alpha \left( e^{-\alpha \partial_j \partial_k (e^\alpha u)} + R^\alpha_j R^\alpha_k f \right) \) is supported at \( \{0\} \), we pick \( \gamma \in S(\mathbb{R}^n) \) whose support does not contain the origin. Then, \( \gamma \) vanishes in a neighborhood of zero. Fix \( \eta \in C^\infty \), which is equal to 1 on the support of \( \gamma \) and vanishes in a smaller neighborhood of zero. Define

\[
\zeta(\xi) = -\eta(\xi) \left( \frac{-i\tilde{\xi}_j}{|\xi|} \right) \left( \frac{-i\tilde{\xi}_k}{|\xi|} \right)
\]

and we notice that \( \zeta \) and all of its derivatives are both bounded \( C^\infty \) functions. Additionally

\[
\eta(\xi)(i\tilde{\xi}_j)(i\tilde{\xi}_k) = \zeta(\xi)(-|\tilde{\xi}|^2).
\]

Taking the FRFT of both side of \( (4.1) \) we obtain that

\[
\mathcal{F}_\alpha(e^{-\alpha \Delta (e^\alpha u)})(\xi) = -|\tilde{\xi}|^2 \mathcal{F}_\alpha(u)(\xi) = \mathcal{F}_\alpha(f)(\xi).
\]

Multiplying by \( \zeta \), we write

\[
\zeta(\xi)\mathcal{F}_\alpha(e^{-\alpha \Delta (e^\alpha u)})(\xi) = -\zeta(\xi)|\tilde{\xi}|^2 \mathcal{F}_\alpha(u)(\xi) = \zeta(\xi)\mathcal{F}_\alpha(f)(\xi).
\]

Since for all \( 1 \leq j, k \leq n \),

\[
\langle \mathcal{F}_\alpha(e^{-\alpha \partial_j \partial_k (e^\alpha u)}), \gamma \rangle = \left\langle (i\tilde{\xi}_j)(i\tilde{\xi}_k) \mathcal{F}_\alpha(u), \gamma \right\rangle = \langle (i\tilde{\xi}_j)(i\tilde{\xi}_k) \mathcal{F}_\alpha(u), \eta \gamma \rangle = \langle \eta(\xi)(i\tilde{\xi}_j)(i\tilde{\xi}_k) \mathcal{F}_\alpha(u), \gamma \rangle = \langle \zeta(\xi)|\tilde{\xi}|^2 \mathcal{F}_\alpha(u), \gamma \rangle = \langle \zeta(\xi)\mathcal{F}_\alpha(f), \gamma \rangle = \left\langle -\eta(\xi) \left( -i\tilde{\xi}_j/|\tilde{\xi}| \right) \left( -i\tilde{\xi}_k/|\tilde{\xi}| \right) \mathcal{F}_\alpha, \gamma \right\rangle = \langle -\eta(\xi) \mathcal{F}_\alpha(R^\alpha_j R^\alpha_k (f)), \gamma \rangle = -\langle \mathcal{F}_\alpha(R^\alpha_j R^\alpha_k (f)), \eta \gamma \rangle = -\langle \mathcal{F}_\alpha(R^\alpha_j R^\alpha_k (f)), \gamma \rangle,
\]

and since the support of \( \gamma \in S(\mathbb{R}^n) \) does not contain the origin, it follows that the function \( \mathcal{F}_\alpha(e^{-\alpha \partial_j \partial_k (e^\alpha u)} + R^\alpha_j R^\alpha_k (f)) \) is supported at \( \{0\} \).

### 5 Numerical simulation of fractional multipliers

In this section, we apply the fractional Riesz transform to an image with the help of the FRFT discrete algorithm ([1, 2, 27]).
As shown in Fig. 5.1, (a) is the original 2-dimensional grayscale image with 400 pixels $\times$ 400 pixels; (c) is the 2-dimensional grayscale image after the Riesz transform of order $(\pi/4, \pi/4)$. In the continuous case, Fig. 5.1 (a) can be regarded as a function of $\mathbb{R}^2$

$$f(x_1, x_2) = \begin{cases} 0, & (x_1, x_2) \in [0, 200]^2 \cup [200, 400]^2, \\ 255, & \text{otherwise.} \end{cases}$$

Fig. 5.1 (b) and (d) are the 3-dimensional color graphs of $f$ and $R_{\pi/4, \pi/4}^\alpha f$. Recall that the fractional Fourier multiplier of the fractional Riesz transform $R_{\pi/4}^\alpha f$ is

$$m_{\pi/4}^\alpha(u) := -i \frac{\tilde{u}_j}{|\tilde{u}|}.$$

Graphs (a) and (b) in Fig. 5.2 indicate that the fractional Riesz transform has the effect of amplitude reduction.

By comparing (c)/(e) and (d)/(f) in Fig. 5.2, as well as the real/imaginary part of $\mathcal{F}_\alpha f$ and the imaginary/real part of $\mathcal{F}_\alpha(R_{\pi/4}^\alpha f)$ accordingly, it can be seen that the fractional Riesz transform has the effect of phase shifting.

Above all, Fig. 5.2 shows that the fractional multiplier of $R_{\pi/4}^\alpha f$ is $-i \tilde{u}_j/|\tilde{u}|$, and thus, the fractional Riesz transform is not only a phase-shifter but also an amplitude...
attenuator. This circumstance is quite different from that of the fractional multiplier of $H_\alpha$, which is only a phase-shift converter with multiplier $-\text{sgn}((\pi - \alpha)u)$.

Figure 5.2: Phase-shifting and amplitude-reducing effect of the fractional Riesz transform in the fractional Fourier domain of order $\alpha = (\pi/4, \pi/4)$ on an image.
6 Application of the fractional Riesz transform in edge detection

Edge detection is a key technology in image processing. It is widely used in biometrics, image understanding, visual attention and other fields. Commonly used image feature extraction methods include the Roberts operator, Prewitt operator, Sobel operator, Laplacian operator and Canny operator. These algorithms extract features based on the gradient changes in the pixel amplitudes. In [16, 33, 34], the authors introduced the image edge detection methods based on the Riesz transform, which can avoid the influence of uneven illumination. Moreover, the Riesz transform has the characteristics of isotropy; therefore, the Riesz transform has more advantages in feature extraction. Based on the principle of Riesz transform edge detection, edge detection based on the fractional Riesz transform is proposed in this section.

When processing the two-dimensional signal $f(x)$, the fractional Riesz transform of $f(x)$ can be expressed as

$$ (R_1^\alpha f)(x) = c_n \text{ p.v. } e^{-\alpha(x)} \left( e_{\alpha f} * \frac{x_1}{|x|^\beta} \right)(x), \quad (6.1) $$

$$ (R_2^\alpha f)(x) = c_n \text{ p.v. } e^{-\alpha(x)} \left( e_{\alpha f} * \frac{x_2}{|x|^\beta} \right)(x), \quad (6.2) $$

or

$$ (R_1^\alpha f)(x) = \mathcal{F}_{-\alpha} \left( -i \frac{u_1 \csc \alpha_1}{\sqrt{(u_1 \csc \alpha_1)^2 + (u_2 \csc \alpha_2)^2}}(\mathcal{F}_\alpha f)(u) \right)(x), \quad (6.3) $$

$$ (R_2^\alpha f)(x) = \mathcal{F}_{-\alpha} \left( -i \frac{u_2 \csc \alpha_2}{\sqrt{(u_1 \csc \alpha_1)^2 + (u_2 \csc \alpha_2)^2}}(\mathcal{F}_\alpha f)(u) \right)(x). \quad (6.4) $$

For an image $f(x)$, the monogenic signal is defined as the combination of $f(x)$ and its fractional Riesz transform.

$$(p(x), q_1(x), q_2(x)) = (f(x), (R_1^\alpha f)(x), (R_2^\alpha f)(x)).$$

Therefore, the local amplitude value $A(x)$, local orientation $\theta(x)$ and local phase $P(x)$ in the monogenic signal in the image can be expressed as

$$ A(x) = \sqrt{p(x)^2 + |q_1(x)|^2 + |q_2(x)|^2} $$

$$ \theta(x) = \tan^{-1} \left( \frac{|q_2(x)|}{|q_1(x)|} \right) $$

$$ P(x) = \tan^{-1} \left( \frac{p(x)}{\sqrt{|q_1(x)|^2 + |q_2(x)|^2}} \right). $$

In this paper, we use the fractional Riesz transform in the form of (6.3) and (6.4) for algorithm design because the fractional Riesz transform can be decomposed into a
combination of a FRFT, inverse FRFT and multiplier by the fractional multiplier Theorem 2.1. Because the FRFT and inverse FRFT have fast algorithms, compared with the form of (6.1) and (6.2), the computational complexity of the algorithm in the form of (6.3) and (6.4) is reduced. Thus, a faster and more efficient operation is realized.

Figure 6.1: Original image and edge detection based on the fractional Riesz transform of order \((\pi/2, \pi/2)\) (i.e., the classical Riesz transform)

Figure 6.2: Extract the information of a specific position in the lateral direction of the image
Figure 6.3: Extract the information of specific position in the longitudinal direction of the image

Figure 6.4: Extract the information of the specific position in the main diagonal of the image
The simulation experiment will be conducted by using the classical Lena image ((a) in Fig. 6.1) as the test image. To better highlight the results of our simulation experiment, we choose an appropriate threshold value to binarize the images after the experiment in such a way that our experimental results show a more obvious effect. Graph (b) in Fig. 6.1 illustrates the result of edge detection based on the fractional Riesz transform of order \([\pi/2, \pi/2]\) (i.e., the classical Riesz transform).

Fig. 6.2 shows that when \(\alpha_2 = \pi/2\) is fixed, if \(\alpha_1\) decreases from \(\pi/2\) ((d), (e), (f) in Fig. 6.2), we extract information about the lateral up position. If \(\alpha_1\) increases from \(\pi/2\) ((a), (b), (c) in Fig. 6.2), we extract information about the lateral down position. In conclusion, by fixed \(\alpha_1 = \pi/2\), we can adjust \(\alpha_2\) to extract information on the specific position in the lateral direction.

Fig. 6.3 indicates that when \(\alpha_2 = \pi/2\) is fixed and \(\alpha_1\) decreases from \(\pi/2\) ((a), (b), (c) in Fig. 6.3), the longitudinal right position information is extracted. As \(\alpha_1\) increases from \(\pi/2\) ((d), (e), (f) in Fig. 6.3), we extract the longitudinal left position information. In conclusion, when fixing \(\alpha_2 = \pi/2\), we can extract information of the specific longitudinal positions by adjusting \(\alpha_1\).

Fig. 6.4 shows that when \(\alpha_1\) and \(\alpha_2\) increase or decrease the same size from \(\pi/2\), the information on the specific direction in the main diagonal is extracted.

Fig. 6.5 indicates that when \(\alpha_1\) increases from \(\pi/2\) and \(\alpha_2\) decreases from \(\pi/2\) by the same size, the information on the specific direction in the antidiagonal is extracted.

The preceding simulation provides a new edge detection tool based on the fractional Riesz transform, that extracts both global features and local features of images. This numerical implementation confirms the belief expressed in [26] that amplitude, phase,
and direction information can be simultaneously extracted by controlling the order of the fractional Riesz transform. We predict that very comprehensive analysis and processing of multidimensional signals, such as images, videos, 3D meshes and animations, can be achieved via the fractional Riesz transforms.

7 Conclusions

In this paper, we introduced the fractional Riesz transform and give the corresponding fractional multiplier theorem and its applications in partial differential equations. We also studied properties of chirp singular integral operators, chirp Hardy spaces and chirp BMO spaces. We used the fractional Riesz transforms in concrete applications in edge detection with surprisingly good results. Our experiments indicate that edge detection can extract local information in any direction by adjusting the order of the fractional Riesz transform. The algorithm complexity of the fractional Riesz transform in the form of (6.3) and (6.4) is reduced compared with the fractional Riesz transform of (6.1) and (6.2).
