Optimal Multiple Assignments Based on Integer Programming in Secret Sharing Schemes with General Access Structures*

Mitsugu Iwamoto†, Hirosuke Yamamoto‡, and Hirohisa Ogawa§

February 1, 2008

Abstract

It is known that for any general access structure, a secret sharing scheme (SSS) can be constructed from an \((m,m)\)-threshold scheme by using the so-called cumulative map or from a \((t,m)\)-threshold SSS by a modified cumulative map. However, such constructed SSSs are not efficient generally. In this paper, we propose a new method to construct a SSS from a \((t,m)\)-threshold scheme for any given general access structure. In the proposed method, integer programming is used to distribute optimally the shares of \((t,m)\)-threshold scheme to each participant of the general access structure. From the optimality, it can always attain lower coding rate than the cumulative maps except the cases that they give the optimal distribution. The same method is also applied to construct SSSs for incomplete access structures and/or ramp access structures.

Key words: Secret sharing schemes, threshold schemes, general access structures, multiple assignment map, cumulative map, ramp schemes, integer programming.

1 Introduction

A Secret Sharing Scheme [1, 2] (SSS) is a method to encrypt a secret information \(S\) into \(n\) pieces called shares \(V_1, V_2, \ldots, V_n\), each of which has no information of the secret \(S\), but \(S\) can be decrypted by collecting several shares. For example, a \((k,n)\)-threshold SSS means that any \(k\) out of \(n\) shares can decrypt the secret \(S\) although any \(k - 1\) or less shares do not leak out any information of \(S\). The \((k,n)\)-threshold access structure can be generalized to so-called general access structures which consist of the families of qualified sets and forbidden sets. A qualified set is the subset of shares that can decrypt the secret, but a forbidden set is the subset that does not leak out any information of \(S\).

Generally, the efficiency of a SSS is measured by the entropy of each share. It is known that for any access structures, the entropies of secret \(S\) and shares \(V_i\), \(i = 1, 2, \ldots, n\), must satisfy \(H(V_i) \geq H(S)\) [3, 4, 5]. On the other hand, in the case of \((k,n)\)-threshold SSSs, the optimal SSSs attaining \(H(V_i) = H(S)\) can easily be constructed [1]. However, it is hard to derive efficient SSSs for arbitrarily given general access structures although several construction methods have been proposed.

For example, the *monotone circuit construction* [6] is a method to realize a SSS by combining several \((m,m)\)-threshold SSSs. This method is simple but inefficient, and hence, it is extended to the *decomposition construction* [7], which uses several decomposed general SSSs. Although the decomposition construction can attain the optimal coding rates for some special access structures, it cannot construct an efficient SSS in the case that the decomposed SSSs cannot be realized efficiently. Note that a monotone circuit construction is based on qualified sets. Hence, as another extension of monotone circuit construction, a method is proposed to construct a SSS with general access structures based on qualified sets and \((t,m)\)-threshold SSSs [8].

On the other hand, for any given general access structure, a SSS can be constructed from a \((t,m)\)-threshold SSS by a multiple assignment map such that \(t\) or more shares of the \((t,m)\)-threshold SSS are assigned to qualified sets but \(t-1\) or less shares are assigned to forbidden sets. The *cumulative map* is a simple realization of the multiple assignment map based on an \((m,m)\)-threshold SSS [9, 10, 11], and from the simplicity, it is often used in visual secret sharing schemes for general access structures [12, 13]. However, it is known that the SSS constructed by the cumulative map is inefficient generally, especially in the case that the access structure is a \((k,n)\)-threshold SSS with \(k \neq n\). Recently, a *modified* cumulative map based on a \((t,m)\)-threshold SSS is proposed to overcome this defect [14]. But, the modified cumulative map is not always more efficient than the original cumulative map.

In this paper, we propose a new construction method that can derive the optimal multiple assignment map by integer programming. The proposed construction method is simple and optimal in the sense of multiple assignment maps. Furthermore, it can also be applied to incomplete and/or ramp access structures.

This paper is organized as follows. In Section 2, we give the definitions of SSSs and introduce the multiple assignment map. We also introduce the construction methods of the cumulative map and the modified cumulative map, and we point out their defects. To overcome such defects, we propose a new construction method of the optimal multiple assignment map by integer programming in Section 3. Finally, Sections 4 and 5 are devoted to present the applications of the proposed method to incomplete or ramp SSSs for general access structures, respectively.

### 2 Preliminaries

#### 2.1 Definitions

Throughout this paper, a set of shares and a family of share sets are represented by bold-face and script letters, respectively. For sets \(A\) and \(B\), we denote a difference set by \(A - B\), which is defined as \(A - B \triangleq A \cap \overline{B}\) where \(\overline{B}\) means the complement of \(B\). Furthermore, the cardinality of \(A\) is represented by \(|A|\), and the Cartesian product of \(A\) and \(B\) is expressed by \(A \times B\).

Let \(V = \{V_1, V_2, \ldots, V_n\}\) be the set of shares, and let \(2^V\) be the family of all subsets of \(V\). We represent the family of qualified sets that can decrypt a secret information \(S\) and the family of forbidden sets that cannot gain any information of \(S\) by \(A_1\) and \(A_0\), respectively.

\(\Gamma = \{A_1, A_0\}\) is called an *access structure*. For instance, the access structure of \((k,n)\)-threshold SSSs can be represented as follows:

\[
A_1 = \{A \in 2^V : k \leq |A| \leq n\},
\]

\[
A_0 = \{A \in 2^V : 0 \leq |A| \leq k - 1\}.
\]
In SSSs, it obviously holds that \( A_1 \cap A_0 = \emptyset \). If it also holds that \( A_1 \cup A_0 = 2^V \), the access structure is called *complete*. Note that any access structure must satisfy the following *monotonicity*.

\[
A \in A_1 \Rightarrow A' \in A_1 \text{ for all } A' \supseteq A \\
A \in A_0 \Rightarrow A' \in A_0 \text{ for all } A' \subseteq A
\]

Therefore, we can define the family of *minimal* qualified sets and the family of *maximal* forbidden sets as follows:

\[
A_1^- = \{ A \in A_1 : A - \{ V \} \not\in A_1 \text{ for any } V \in A \},
\]

\[
A_0^+ = \{ A \in A_0 : A \cup \{ V \} \not\in A_0 \text{ for any } V \in V - A \}.
\]

We assume that the secret information \( S \) and each share \( V_i \) are random variables, which take values in finite fields \( F_S \) and \( F_{V_i} \), respectively. Then, share set \( A = \{ V_1, V_2, \ldots, V_n \} (\subseteq V) \), which takes values in \( F_A = F_{V_1} \times F_{V_2} \times \cdots \times F_{V_n} \), must satisfy the following conditions:

\[
H(S|A) = H(S) \text{ if } A \in A_0, \\
H(S|A) = 0 \text{ if } A \in A_1,
\]

where \( H(S) \) is the entropy of \( S \) and \( H(S|A) \) is the conditional entropy of \( S \) for given \( A \).

Now, let us define the coding rate of a share \( V_i \) as \( \rho_i = H(V_i)/H(S) \), for \( i = 1, 2, \ldots, n \). Since each \( \rho_i \) may be different in the case of general access structures, it is cumbersome to treat each \( \rho_i \) independently. Hence, we consider only the following *average* coding rate \( \bar{\rho} \) and *worst* coding rate \( \rho^* \).

\[
\bar{\rho} = \frac{1}{n} \sum_{i=1}^{n} \rho_i, \\
\rho^* = \max_{1 \leq i \leq n} \rho_i.
\]

For a given access structure \( \Gamma = \{ A_1, A_0 \} \), we call \( V \in V \) a *significant* share if there exists a share set \( A \in 2^V \) such that \( A \cup \{ V \} \in A_1 \) but \( A \in A_0 \).

**Remark 1** Note that a non-significant share plays no roll in the SSS, and hence, \( \rho_i = 0 \) can always be attained for each non-significant share \( V_i \) in any access structure \( \Gamma \). Furthermore, if there exists a non-significant share \( V_i \) with \( \rho_i > 0 \), the average coding rate can be reduced by setting \( \rho_i = 0 \) without changing all the significant shares. Hence, we call a non-significant share a *vacuous* share. On the other hand, we have \( \rho_i \geq 1 \) for any significant share \( V_i \) because it must satisfy \( H(V_i) \geq H(S) \) \([4, 5, 3]\). In the following, we assume that every share is significant.

If a SSS attains \( \rho_i = 1 \) for all \( i \), it is called *ideal*. It is known that in the case of \((k, n)\)-threshold SSSs, the ideal SSS can easily be constructed for any \( k \) and \( n \) \([1]\). Since \( \rho_i \geq 1, i = 1, 2, \ldots, n \), must hold for any significant share \( V_i \) in any access structures, \( \bar{\rho} = 1 \) or \( \rho^* = 1 \) are the necessary and sufficient conditions for a SSS to be ideal \([4]\).

### 2.2 Multiple Assignment Map

Let \( \Gamma = \{ A_1, A_0 \} \) be a given general access structure with share set \( V = \{ V_1, V_2, \ldots, V_n \} \) and let \( W(t,m) = \{ W_1(t), W_2(t), \ldots, W_m(t) \} \) be the share set of a \((t,m)\)-threshold SSS. We now consider a map
Assume that the access structure \( \Gamma \) is \( t,m \)-threshold. The above multiple assignment map \( \psi \) is realized for any access structures \([9, 10, 11]\). Suppose that the access structure \( \Gamma = (V, T) \)-threshold SSS can easily be constructed as an ideal SSS \([1, 3]\), we assume in this case of \( \Gamma \)-threshold scheme, and a map \( \Phi : 2^V \rightarrow 2^{W_{(t,m)}} \), which is defined as \( \Phi(A) \) as follows.

\[
\Phi(A) = \bigcup_{i \in A} \varphi(i),
\]

where \( \varphi(i) \) is the set of \( \varphi \) vulnerabilities of an \((t,m)\)-threshold SSS with \( \varphi \) is \( \varphi \) vulnerabilities of an ideal SSS.

Then, consider the map \( \psi : 2^V \rightarrow 2^{W_{(t,m)}} \) defined by

\[
\psi(i) = \bigcup_{j : i \in F_j} W_j^{(m)}
\]

where \( F_j \) is a set of primitive shares of an \((m,m)\)-threshold SSS. The above multiple assignment map \( \psi \) is called the **cumulative map**.

**Example 2** Assume that \( n = 4 \) and access structure \( \Gamma_1 \) is defined by

\[
\begin{align*}
\mathcal{A}_1^+ &= \{V_1, V_2, V_3\}, \\
\mathcal{A}_0^+ &= \{V_1, V_2\}, \{V_1, V_3\}, \{V_2, V_3\}, \{V_4\}.
\end{align*}
\]

Then, \( m = |\mathcal{A}_0^+| = 4 \), and the cumulative map \( \psi_{\Gamma_1} \) is given from (17) as follows.

\[
\begin{align*}
V_1 &= \psi_{\Gamma_1}(1) = \left\{W_3^{(4)}, W_4^{(4)}\right\}, \\
V_2 &= \psi_{\Gamma_1}(2) = \left\{W_2^{(4)}, W_4^{(4)}\right\}, \\
V_3 &= \psi_{\Gamma_1}(3) = \left\{W_1^{(4)}, W_4^{(4)}\right\}, \\
V_4 &= \psi_{\Gamma_1}(4) = \left\{W_1^{(4)}, W_2^{(4)}, W_3^{(4)}\right\}.
\end{align*}
\]

In this example, it holds that \( \tilde{\rho} = 9/4 \) and \( \rho^* = 3 \).
It is known that the next theorem holds for the cumulative map $\psi_T$.

**Theorem 3 ([15])** For any multiple assignment map $\varphi_T : \{1, 2, \ldots, n\} \rightarrow 2^W(t,m)$ with $t = m$, it must hold that $|W_{(m,m)}| \geq \left| A_0^+ \right|$, i.e., $m \geq \left| A_0^+ \right|$. The equality holds if and only if $\varphi_T(i)$ is equal to the cumulative map $\psi_T(i)$ defined by (17), where we assume that all $\psi_T$’s obtained by permutations of $F_j$’s in (16) are the same.

Theorem 3 means that, in the case of $t = m$, the cumulative map $\psi_T$ minimizes the number of primitive shares $m$. But, the minimization of $m$ does not mean the realization of an efficient SSS generally because it does not minimize the average coding rate $\tilde{\rho}$ and/or the worst coding rate $\rho^*$.

For instance, consider the case that $\Gamma$ is a $(k,n)$-threshold access structure with $k \neq n$. If we construct shares $V_i$ by the cumulative map $\psi$ for this $\Gamma$, each $V_i$ must consist of $\left(\binom{n-1}{k-1}\right)$ primitive shares of an $\left(\binom{n}{k-1}, \binom{n}{k-1}\right)$-threshold SSS because of $|A_0^+| = \binom{n}{k-1}$. This means that $\tilde{\rho} = \rho^* = \binom{n-1}{k-1}$. But, if we use the $(k,n)$-threshold SSS itself, we have $\tilde{\rho} = \rho^* = 1$ because each $V_i$ consists of one primitive share. Hence, the cumulative map is quite inefficient in the case that $\Gamma$ is a $(k,n)$-threshold access structure. In order to overcome this defect, a modified cumulative map is proposed in [14] based on $(t,m)$-threshold SSSs. The modified cumulative map $\psi_T'$ is constructed as follows.

**Construction 4 ([14])** For a given $\Gamma = \{A_0^+, A_1^+\}$ and a positive integer $g \overset{\text{def}}{=} \min_{A \in A_1^+} |A|$, let $G_0 \subseteq A_0^+$ be the family defined by

$$G_0 = \{G \in A_0^+ : |G| \geq g\}. \tag{24}$$

When $G_0 = \{G_1, G_2, \ldots, G_u\} \neq \emptyset$, let $\ell_j \overset{\text{def}}{=} |G_j| - g + 1$ for $j = 1, 2, \ldots, u$, and $\ell_j \overset{\text{def}}{=} \sum_{p=1}^{j} l_p$. If $G_0 = \emptyset$, let $u = 1$ and $\ell_1 = 0$. Then, consider a $(g + \ell_u, n + \ell_u)$-threshold SSS and the set of primitive shares $W_{(g+\ell_u, n+\ell_u)} = \{W_1^{(g+\ell_u)}, W_2^{(g+\ell_u)}, \ldots, W_{n+\ell_u}^{(g+\ell_u)}\}$. Furthermore, let $U_j, j = 1, 2, \ldots, u$, be the subset of primitive shares defined by

$$U_1 = \emptyset \quad \text{if} \quad G_0 = \emptyset, \tag{25}$$

$$U_j = \left\{ W_{n+\ell_j-1+1}^{(g+\ell_u)}, W_{n+\ell_j-1+2}^{(g+\ell_u)}, \ldots, W_{n+\ell_j}^{(g+\ell_u)} \right\} \quad \text{if} \quad G_0 \neq \emptyset, \tag{26}$$

where $\ell_0 = 0$. Then, the modified cumulative map $\psi_T'$ is defined by

$$\psi_T'(i) = \left\{ W_i^{(g+\ell_u)} \right\} \cup \left\{ \bigcup_{j: V_j \notin G_j} U_j \right\}. \tag{27}$$

In the case where $\Gamma$ is a $(k,n)$-threshold access structure, it holds that $G_0 = \emptyset$ and $U_1 = \emptyset$, and hence, it holds that $\psi_T'(i) = \{W_i^{(k)}\}$ for $i = 1, 2, \ldots, n$ and this scheme coincides with the ideal $(k,n)$-threshold SSS [14]. Therefore, the modified cumulative map $\psi_T'$ is efficient if $\Gamma$ is, or is near to, a $(k,n)$-threshold access structures. Furthermore, it is shown in [14] that if the access structure $\Gamma$ satisfies

$$|A_0^+| \geq \frac{(n-g-1)\ell_u + n + 2|G_0|}{n - g + 1}, \tag{28}$$

then it holds that for the original cumulative map $\psi_T$, $\sum_{V_i \in V} |\psi_T'(i)| \leq \sum_{V_i \in V} |\psi_T(i)|$, which means that the average coding rate $\tilde{\rho}$ of $\psi_T'$ is smaller than or equal to $\psi_T$.

But, as shown in the following example, $\psi_T'$ is not always more efficient than $\psi_T$ if $\Gamma$ does not satisfy (28).
Example 5 Consider the access structure $\Gamma_1$ given by (18) and (19) in Example 2, which does not satisfy (28). Since we have $g = 2$ from (18), $G_0$ becomes $G_0 = \{\{V_1, V_2\}, \{V_1, V_3\}, \{V_2, V_3\}\} \overset{\text{def}}{=} \{G_1, G_2, G_3\}$. Furthermore, since we have that $l_1 = l_2 = l_3 = 1$ and $\ell_u = 3$, $U_i$'s are determined as $U_1 = \{W_5^{(5)}\}$, $U_2 = \{W_6^{(5)}\}$, $U_3 = \{W_7^{(5)}\}$ for $W_{(5,7)} = \{W_1^{(5)}, W_2^{(5)}, \ldots, W_7^{(5)}\}$. Hence, we can check that $\Gamma_1$ does not satisfy (28) because of $|A_0^+| = 4$, $n = 4$, $g = 2$, $\ell_u = 3$, and $|G_0| = 3$. Finally, we have from (27) that

$$V_1 = \psi'_{\Gamma_1}(1) = \left\{W_1^{(5)}, W_7^{(5)}\right\},$$

$$V_2 = \psi'_{\Gamma_1}(2) = \left\{W_2^{(5)}, W_6^{(5)}\right\},$$

$$V_3 = \psi'_{\Gamma_1}(3) = \left\{W_3^{(5)}, W_5^{(5)}\right\},$$

$$V_4 = \psi'_{\Gamma_1}(4) = \left\{W_4^{(5)}, W_5^{(5)}, W_6^{(5)}, W_7^{(5)}\right\}.$$  

In this example, the coding rates are given by $\tilde{\rho} = 5/2$ and $\rho^* = 4$, which are larger than the coding rates of Example 2, i.e., $\tilde{\rho} = 9/4$ and $\rho^* = 3$.

Note that (28) does not guarantee that the worst coding rate $\rho^*$ of $\psi'_{\Gamma}$ is smaller than $\psi_{\Gamma}$. Actually, the next example shows a case where $\psi'_{\Gamma}$ attains a smaller average coding rate but gives larger worst coding rate than $\psi_{\Gamma}$.

Example 6 Consider the access structure $\Gamma_2$ given by

$$\mathcal{A}_1^- = \{\{V_1, V_2, V_3, V_5\}, \{V_1, V_2, V_4\}, \{V_1, V_3, V_4\}, \{V_1, V_4, V_5\},$$

$$\{V_2, V_3, V_4\}, \{V_2, V_4, V_5\}, \{V_3, V_4, V_5\}\},$$

$$\mathcal{A}_0^+ = \{\{V_1, V_2, V_3\}, \{V_1, V_2, V_5\}, \{V_1, V_3, V_5\}, \{V_2, V_3, V_5\},$$

$$\{V_1, V_4\}, \{V_2, V_4\}, \{V_3, V_4\}, \{V_4, V_5\}\}.$$  

Then, the cumulative map $\psi_{\Gamma_2}$ is constructed as follows:

$$V_1 = \psi_{\Gamma_2}(1) = \left\{W_4^{(8)}, W_6^{(8)}, W_7^{(8)}, W_8^{(8)}\right\},$$

$$V_2 = \psi_{\Gamma_2}(2) = \left\{W_3^{(8)}, W_5^{(8)}, W_7^{(8)}, W_8^{(8)}\right\},$$

$$V_3 = \psi_{\Gamma_2}(3) = \left\{W_2^{(8)}, W_5^{(8)}, W_6^{(8)}, W_8^{(8)}\right\},$$

$$V_4 = \psi_{\Gamma_2}(4) = \left\{W_1^{(8)}, W_2^{(8)}, W_3^{(8)}, W_4^{(8)}\right\},$$

$$V_5 = \psi_{\Gamma_2}(5) = \left\{W_1^{(8)}, W_5^{(8)}, W_6^{(8)}, W_7^{(8)}\right\},$$

which attains that $\tilde{\rho} = \rho^* = 4$. On the other hand, the modified cumulative map $\psi'_{\Gamma_2}$ is given by

$$V_1 = \psi'_{\Gamma_2}(1) = \left\{W_1^{(7)}, W_9^{(7)}\right\},$$

$$V_2 = \psi'_{\Gamma_2}(2) = \left\{W_2^{(7)}, W_8^{(7)}\right\},$$

$$V_3 = \psi'_{\Gamma_2}(3) = \left\{W_3^{(7)}, W_7^{(7)}\right\},$$

$$V_4 = \psi'_{\Gamma_2}(4) = \left\{W_4^{(7)}, W_6^{(7)}, W_7^{(7)}, W_8^{(7)}, W_9^{(7)}\right\},$$

$$V_5 = \psi'_{\Gamma_2}(5) = \left\{W_5^{(7)}, W_6^{(7)}\right\}.$$
Observe that the rates of \( \psi_{t,2}' \) are given by \( \tilde{\rho} = 13/5, \rho^* = 5 \). Hence, \( \psi_{t,2}' \) gives smaller \( \tilde{\rho} \) but larger \( \rho^* \) than \( \psi_{t,2} \). \( \square \)

As shown in Examples 5 and 6, the modified cumulative map cannot always overcome the defects of the original cumulative maps. Hence, in the next section, we propose a construction method of multiple assignment maps that can attain the optimal average or worst case coding rates based on integer programming.

## 3 Optimal Multiple Assignment Maps

For a multiple assignment map \( \varphi_T : \{1, 2, \ldots, n\} \rightarrow 2^{\mathbf{W}_{(t,m)}} \), a set \( \mathbf{A} \subseteq \mathbf{V} \), and \( p \in \{0, 1, \ldots, 2^n - 1\} \), let \( \mathbf{X}_p \) be the subset of \( \mathbf{W}_{(t,m)} \) defined by

\[
\mathbf{X}_p = \left[ \bigcap_{i \in b(p)} \varphi_T(i) \right] \cap \left[ \bigcap_{i \notin b(p)} \varphi_T(i) \right],
\]

where \( b(p) \) is the \( i \)-th least significant bit in the \( n \)-bit binary representation of \( p \). For example, in the case of \( p = 5 \) and \( n = 4 \), it holds that \( b(5)_1 = b(5)_3 = 1 \), and (45) becomes \( \mathbf{X}_5 = \varphi_T(4) \cap \varphi_T(3) \cap \varphi_T(2) \cap \varphi_T(1) \). Figure 1 is the Venn diagram which shows the relation between \( \mathbf{X}_p \)'s and \( \varphi_T(i) \)'s in the case of \( n = 3 \). Since \( \varphi_T \) must satisfy (13), it must hold that \( \bigcap_{i=1}^{n} \varphi_T(i) = \emptyset \), which implies that \( \mathbf{X}_0 = \emptyset \). Hence, we consider only \( \mathbf{X}_p \) for \( p = 1, 2, \ldots, 2^n - 1 \) in the following.

Then, it is easy to check that \( \mathbf{X}_p \)'s satisfy the following equations for an arbitrary \( n \) and \( N = 2^n - 1 \).

\[
\mathbf{X}_p \cap \mathbf{X}_{p'} = \emptyset \quad \text{if} \quad p \neq p',
\]

\[
\varphi_T(i) = \bigcup_{p : b(p)_i = 1} \mathbf{X}_p
\]

\[
\Phi_T(\mathbf{A}) = \bigcup_{V_i \in \mathbf{A}} \varphi_T(i) = \bigcup_{p : b(p)_i = 1} \mathbf{X}_p \quad \text{for some} \quad V_i \in \mathbf{A}
\]

Letting \( x_p = |\mathbf{X}_p| \), the cardinality of \( \Phi_T(\mathbf{A}) \) is given by

\[
|\Phi_T(\mathbf{A})| = \sum_{p : b(p)_i = 1} x_p \quad \text{for some} \quad V_i \in \mathbf{A}
\]

from (46) and (48).

Now, we describe how to design the optimal multiple assignment map \( \varphi_T \) which attains the minimum average coding rate. Note that, in order to design the multiple assignment map \( \varphi_T \) for the set of primitive shares \( \mathbf{W}_{(t,m)} \), we have to determine only \( x_p, p = 1, 2, \ldots, N \), and \( t \), since \( m \) can be calculated as \( m = \sum_{p=1}^{N} x_p \) from (13) and (49).

Let \( \mathbf{y} = [t, x_1, x_2, \ldots, x_N] \) be the \((N + 1)\)-dimensional parameter vector to minimize the average coding rate. Furthermore, for an integer \( \ell \) and a share set \( \mathbf{A} \), define an \((N + 1)\)-dimensional row vector \( \mathbf{a}(\ell, \mathbf{A}) = [\ell, 1(\mathbf{A})_1, 1(\mathbf{A})_2, \ldots, 1(\mathbf{A})_N] \) where

\[
1(\mathbf{A})_p = \begin{cases} 1 & \text{if} \ b(p)_i = 1 \text{ for some} \ V_i \in \mathbf{A} \\ 0 & \text{otherwise.} \end{cases}
\]
Then, since (49) can be represented by inner product as $|\Phi_\Gamma(A)| = a(0; A) \cdot y^T$ where superscript $T$ means the transpose of vector $y$, the inequalities in the constraints (11) and (12) can be represented by $a(0; A) \cdot y^T \geq t$, and $a(0; A) \cdot y^T \leq t - 1$, respectively. Therefore, these constraints can be expressed as

$$a(-1; A) \cdot y^T \geq 0 \quad \text{if} \quad A \in \mathcal{A}^-_1,$$

$$-a(-1; A) \cdot y^T - 1 \geq 0 \quad \text{if} \quad A \in \mathcal{A}^+_0,$$

respectively. Furthermore, denoting the Hamming weight in the binary representation of $p$ by $h_p$, it holds from (47) that

$$\sum_{i=1}^{n} |\varphi_\Gamma(i)| = \sum_{i=1}^{n} \sum_{p : b(p)_i = 1} x_p = \sum_{p=1}^{N} h_p x_p = h \cdot y^T,$$

where $h = [h_0, h_1, \ldots, h_N] \in \mathbb{Z}^{N+1}$. Hence, the average coding rate $\tilde{\rho}$ in (14) is given by $1/n \cdot h \cdot y^T$ which we want to minimize.

We note here that $a(\cdot; \cdot)$ and $h$ do not depend on the multiple assignment map $\varphi_\Gamma$, and hence, summarizing (50)–(53), we can formulate the integer programming problem $\text{IP}_{\tilde{\rho}}(\Gamma)$ that minimizes the average coding rate $\tilde{\rho}$ under the constraints of (11) and (12) as follows:

$$\begin{align*}
\text{IP}_{\tilde{\rho}}(\Gamma) \\
\quad \text{minimize} \quad & h \cdot y^T \\
\quad \text{subject to} \quad & a(-1; A) \cdot y^T \geq 0 \quad \text{for} \quad A \in \mathcal{A}^-_1 \\
& -a(-1; A) \cdot y^T - 1 \geq 0 \quad \text{for} \quad A \in \mathcal{A}^+_0 \\
& y \geq 0
\end{align*}$$
The optimal multiple assignment map \( \tilde{\varphi}_T \) that attains the minimum average coding rate can be constructed as follows. First, let \( \tilde{y} = [\tilde{t}, \tilde{x}_1, \ldots, \tilde{x}_N] \) be the minimizers of the integer programming problem \( \text{IP}_{\tilde{\rho}}(\Gamma) \), and we used the \((\tilde{t}, \tilde{m})\)-threshold SSS with primitive shares \( \mathbf{W}_{(\tilde{t}, \tilde{m})} = \{W_{1(\tilde{t})}, \ldots, W_{m(\tilde{t})}\} \) for secret \( S \) where \( \tilde{m} \) can be calculated from \( \tilde{m} = \sum_{p=1}^N \tilde{x}_p \). Then, for each \( p \), we can assign \( \tilde{x}_p \) different primitive shares of \( \mathbf{W}_{(\tilde{t}, \tilde{m})} \) to \( \mathbf{X}_p \) that satisfies \( |\mathbf{X}_p| = \tilde{x}_p \) and (46). Finally, the multiple assignment map \( \tilde{\varphi}_T \) is obtained by (47).

Next, we consider the integer programming problem \( \text{IP}_{\rho^*}(\Gamma) \) that minimizes the worst coding rate \( \rho^* \). Let \( M \) be the maximal number of assigned primitive shares among all \( V_i \), \( i = 1, 2, \ldots, n \). Then, it holds that \( |\varphi_T(i)| \leq M \) for all \( i = 1, 2, \ldots, n \), and the minimization of \( M \) attains the optimal worst coding rate. Now, let \( z \) be the \((N+2)\)-dimensional parameter vector defined by 

\[
z = [M, t, x_1, x_2, \ldots, x_N].
\]

Then, it holds that \( M = e \cdot z^T \) where \( e \) is the \((N+2)\)-dimensional row vector defined by 

\[
e = [1, 0, 0, \ldots, 0].
\]

Furthermore, by defining 

\[
b(\ell, \ell'; A) = [\ell, \ell', 1(A)_1, 1(A)_2, \ldots, 1(A)_N]
\]

where \( 1(A)_p \) is defined by (50), the number of primitive shares assigned to a share set \( A \subseteq V \) can be expressed as \( b(0, 0; A) \cdot z^T \). Hence, in the same way as \( \text{IP}_{\tilde{\rho}}(\Gamma) \), the integer programming problem \( \text{IP}_{\rho^*}(\Gamma) \) that minimizes the worst coding rate \( \rho^* \) can be formulated as follows:

\[
\begin{align*}
\text{minimize} & \quad e \cdot z^T \\
\text{subject to} & \quad b(0, -1; A) \cdot z^T \geq 0 \quad \text{for} \quad A \in A^-_1 \\
& \quad -b(0, -1; A) \cdot z^T \geq 1 \quad \text{for} \quad A \in A^+_1 \\
& \quad -b(-1, 0; \{V\}) \cdot z^T \geq 0 \quad \text{for} \quad V \in V \\
& \quad z \geq 0
\end{align*}
\]

The multiple assignment map \( \varphi_T^* \) attaining the minimum \( \rho^* \) can also be constructed from the obtained minimizer in the same way as the construction of \( \tilde{\varphi}_T \).

**Remark 7** Actually, in SSSs, we can assume without loss of generality that \( x_N = 0 \), i.e., \( X_N = \bigcap_{i=1}^n \varphi_T(i) = 0 \) because it is not necessary to consider the set of primitive shares commonly contained in every share. Hence, the vectors in integer programming problems \( \text{IP}_{\tilde{\rho}}(\Gamma) \) and \( \text{IP}_{\rho^*}(\Gamma) \) can be reduced to \( N \)-dimensional and \((N+1)\)-dimensional vectors, respectively. However, \( x_N = 0 \) does not hold generally in the case of ramp SS schemes, which is described in Remark 20 in Section 5.2.

**Example 8** For the access structure \( \Gamma_1 \) defined by (18) and (19) in Example 2, the integer programming problem \( \text{IP}_{\tilde{\rho}}(\Gamma_1) \) can be formulated as follows:

\[
\begin{align*}
\text{minimize} & \quad x_1 + x_2 + 2x_3 + x_4 + 2x_5 + 2x_6 + 3x_7 + x_8 + 2x_9 + 2x_{10} \\
& \quad + 3x_{11} + 2x_{12} + 3x_{13} + 3x_{14} \\
\text{subject to} & \quad -t + x_1 + x_2 + x_3 + x_4 + x_5 + x_6 + x_7 + x_9 \\
& \quad + x_{10} + x_{11} + x_{12} + x_{13} + x_{14} \geq 0 \\
& \quad -t + x_1 + x_3 + x_5 + x_7 + x_8 + x_9 + x_{10} + x_{11} + x_{12} + x_{13} + x_{14} \geq 0 \\
& \quad -t + x_2 + x_3 + x_6 + x_7 + x_8 + x_9 + x_{10} + x_{11} + x_{12} + x_{13} + x_{14} \geq 0 \\
& \quad -t + x_4 + x_5 + x_6 + x_7 + x_8 + x_9 + x_{10} + x_{11} + x_{12} + x_{13} + x_{14} \geq 0 \\
& \quad t - x_1 - x_2 - x_3 - x_5 - x_6 - x_7 - x_9 - x_{10} - x_{11} - x_{12} - x_{13} - x_{14} \geq 1 \\
& \quad t - x_1 - x_3 - x_4 - x_5 - x_6 - x_7 - x_9 - x_{11} - x_{12} - x_{13} - x_{14} \geq 1 \\
& \quad t - x_2 - x_3 - x_4 - x_5 - x_6 - x_7 - x_{10} - x_{11} - x_{12} - x_{13} - x_{14} \geq 1 \\
& \quad t - x_8 - x_9 - x_{10} - x_{11} - x_{12} - x_{13} - x_{14} \geq 1 \\
x_p \geq 0, p = 1, 2, \ldots, 14
\end{align*}
\]
By solving the above IP$_\tilde{\rho}(\Gamma_1)$, we obtain that the value of the objective function is 5, which is attained by the following minimizers:

\[
\tilde{t} = 3, \quad \tilde{x}_1 = \tilde{x}_2 = \tilde{x}_4 = 1, \quad \tilde{x}_8 = 2, \quad \tilde{x}_i = 0 \quad \text{for} \quad i = 3, 5, 6, 7, 9, 10, \ldots, 14,
\]

Hence, \(\tilde{m}\) is given by \(\tilde{m} = \sum_{p=1}^{14} \tilde{x}_p = 5\), and \(X_p\)'s become

\[
X_1 = \left\{ W_1^{(3)} \right\}, \quad X_2 = \left\{ W_2^{(3)} \right\}, \quad X_4 = \left\{ W_3^{(3)} \right\}, \quad X_8 = \left\{ W_4^{(3)}, W_5^{(3)} \right\},
\]

where \(W_{(3,5)} = \{W_1^{(3)}, W_2^{(3)}, \ldots, W_5^{(3)}\}\). Finally, from (47), \(\tilde{\varphi}_{\Gamma_1}\) is constructed as

\[
V_1 = \bar{\varphi}_{\Gamma_1}(1) = \left\{ W_1^{(3)} \right\}, \quad (56)
\]

\[
V_2 = \bar{\varphi}_{\Gamma_1}(2) = \left\{ W_2^{(3)} \right\}, \quad (57)
\]

\[
V_3 = \bar{\varphi}_{\Gamma_1}(3) = \left\{ W_3^{(3)} \right\}, \quad (58)
\]

\[
V_4 = \bar{\varphi}_{\Gamma_1}(4) = \left\{ W_4^{(3)}, W_5^{(3)} \right\}. \quad (59)
\]

In this case, we have that \(\bar{\rho} = 5/4\) and \(\rho^* = 2\). The integer programming problem IP$_{\rho^*}(\Gamma_1)$ derives the same solutions as (54), and hence, it holds that \(\bar{\varphi}_{\Gamma_1} = \bar{\varphi}_{\Gamma_1}^*\) in this example. Recall that the cumulative map \(\psi_{\Gamma_1}\) attains the coding rates \(\bar{\rho} = 9/4\) and \(\rho^* = 3\), and the modified cumulative map \(\psi_{\Gamma_1}^t\) attains \(\tilde{\rho} = 5/2\) and \(\rho^* = 4\). Hence, \(\varphi_{\Gamma_1}\) can attain smaller coding rates compared with \(\psi_{\Gamma_1}\) and \(\psi_{\Gamma_1}^t\).

**Example 9** For the access structure \(\Gamma_2\) defined by (33) and (34) in Example 6, we can obtain the following multiple assignment map by solving the integer programming problem IP$_{\tilde{\rho}}(\Gamma_2)$.

\[
V_1 = \bar{\varphi}_{\Gamma_2}(1) = \left\{ W_1^{(4)} \right\}, \quad (60)
\]

\[
V_2 = \bar{\varphi}_{\Gamma_2}(2) = \left\{ W_2^{(4)} \right\}, \quad (61)
\]

\[
V_3 = \bar{\varphi}_{\Gamma_2}(3) = \left\{ W_3^{(4)} \right\}, \quad (62)
\]

\[
V_4 = \bar{\varphi}_{\Gamma_2}(4) = \left\{ W_4^{(4)}, W_5^{(4)} \right\}, \quad (63)
\]

\[
V_5 = \bar{\varphi}_{\Gamma_2}(5) = \left\{ W_6^{(4)} \right\}. \quad (64)
\]

where \(W_i^{(4)} \in W_{(4,6)}\). Then, it holds that \(\tilde{\rho} = 6/5\) and \(\rho^* = 2\). Furthermore, it holds that \(\bar{\varphi}_{\Gamma_2} = \bar{\varphi}_{\Gamma_2}^*\) in this access structure. Recall again that the cumulative map \(\psi_{\Gamma_2}\) attains the coding rates \(\bar{\rho} = \rho^* = 4\), and the modified cumulative map \(\psi_{\Gamma_2}^t\) attains \(\tilde{\rho} = 13/5\) and \(\rho^* = 5\). Hence, \(\bar{\varphi}_{\Gamma_2}\) is more efficient than \(\psi_{\Gamma_2}\) and \(\psi_{\Gamma_2}^t\).

Since any access structure can be realized by the cumulative map (and the modified cumulative map), there exists at least one multiple assignment map for any access structure. Therefore, the next theorem holds obviously.

**Theorem 10** For any access structure \(\Gamma\) that satisfies monotonicity (3) and (4), the integer programming problems IP$_{\tilde{\rho}}(\Gamma)$ and IP$_{\rho^*}(\Gamma)$ always have at least one feasible solution, and hence, there exists the optimal multiple assignment map.
We note that the integer programming problems are NP-hard, and hence, the proposed algorithms may take much time in solving for large \( n = |V| \). But, in the case that \( n \) is not large, the solution is obtained quickly. For instance, in the case of \( IP_{\tilde{\rho}}(\Gamma_3) \) in Example 11 with \( n = 6 \), it can be solved within 0.1 seconds by a notebook computer.

**Example 11** Consider the following access structure \( \Gamma_3 \):

\[
\mathcal{A}_1^- = \{ \{V_1, V_3, V_4, V_5\}, \{V_1, V_3, V_5, V_6\}, \{V_1, V_4, V_5, V_6\}, \{V_3, V_4, V_5, V_6\}, \{V_1, V_2, V_3\}, \{V_1, V_2, V_6\}, \{V_2, V_3, V_4\}, \{V_2, V_3, V_5\}, \{V_2, V_4, V_5\}, \{V_2, V_4, V_6\}, \{V_2, V_5, V_6\}, \}
\]

\[
\mathcal{A}_0^+ = \{ \{V_1, V_3, V_4, V_6\}, \{V_1, V_2, V_4\}, \{V_1, V_3, V_5\}, \{V_1, V_4, V_5\}, \{V_1, V_5, V_6\}, \{V_3, V_4, V_5\}, \{V_3, V_5, V_6\}, \{V_4, V_5, V_6\}, \{V_2, V_3\}, \{V_2, V_5\}, \{V_2, V_6\}. \}
\]

Then, we obtain the following multiple assignment map by solving \( IP_{\tilde{\rho}}(\Gamma_3) \).

\[
V_1 = \varphi_{\Gamma_3}(1) = \left\{ W_1^{(6)}, W_2^{(6)} \right\},
\]

\[
V_2 = \varphi_{\Gamma_3}(2) = \left\{ W_1^{(6)}, W_3^{(6)}, W_4^{(6)}, W_5^{(6)} \right\},
\]

\[
V_3 = \varphi_{\Gamma_3}(3) = \left\{ W_6^{(6)} \right\},
\]

\[
V_4 = \varphi_{\Gamma_3}(4) = \left\{ W_2^{(6)}, W_5^{(6)} \right\},
\]

\[
V_5 = \varphi_{\Gamma_3}(5) = \left\{ W_3^{(6)}, W_7^{(6)} \right\},
\]

\[
V_6 = \varphi_{\Gamma_3}(6) = \left\{ W_8^{(6)} \right\},
\]

where \( W_i^{(6)} \in \mathcal{W}_{(6,8)} \). \( \varphi_{\Gamma_3} \) attains that \( \tilde{\rho} = 2 \) and \( \rho^* = 4 \). On the other hand, the cumulative map for the access structure \( \Gamma_3 \) are given by

\[
V_1 = \psi_{\Gamma_3}(1) = \left\{ W_6^{(11)}, W_7^{(11)}, W_8^{(11)}, W_9^{(11)}, W_{10}^{(11)}, W_{11}^{(11)} \right\},
\]

\[
V_2 = \psi_{\Gamma_3}(2) = \left\{ W_1^{(11)}, W_3^{(11)}, W_4^{(11)}, W_5^{(11)}, W_6^{(11)}, W_7^{(11)}, W_8^{(11)} \right\},
\]

\[
V_3 = \psi_{\Gamma_3}(3) = \left\{ W_2^{(11)}, W_4^{(11)}, W_5^{(11)}, W_8^{(11)}, W_{10}^{(11)}, W_{11}^{(11)} \right\},
\]

\[
V_4 = \psi_{\Gamma_3}(4) = \left\{ W_3^{(11)}, W_5^{(11)}, W_7^{(11)}, W_9^{(11)}, W_{10}^{(11)}, W_{11}^{(11)} \right\},
\]

\[
V_5 = \psi_{\Gamma_3}(5) = \left\{ W_1^{(11)}, W_2^{(11)}, W_9^{(11)}, W_{11}^{(11)} \right\},
\]

\[
V_6 = \psi_{\Gamma_3}(6) = \left\{ W_2^{(11)}, W_3^{(11)}, W_4^{(11)}, W_6^{(11)}, W_9^{(11)}, W_{10}^{(11)} \right\},
\]

where \( W_i^{(11)} \in \mathcal{W}_{(11,11)} \). \( \psi_{\Gamma_3} \) has \( \tilde{\rho} = 35/6 \) and \( \rho^* = 7 \). Furthermore, the modified cumulative map for \( \Gamma_3 \) requires \( (12,15) \)-threshold SSS and has \( \tilde{\rho} = 5 \) and \( \rho^* = 9 \). \( \square \)

Next, we clarify what kind of access structure can be realized as an ideal SSS by the multiple assignment map.

**Theorem 12** For an access structure \( \Gamma \), the SSS constructed by the optimal multiple assignment map is ideal, i.e., \( \rho_i = 1 \) for all \( i \), if and only if \( \mathcal{A}_1^- \) of \( \Gamma \) can be represented by

\[
\mathcal{A}_1^- = \bigcup_{\forall j_1, j_2, \ldots, j_t \in \{1,2,\ldots,m\}} \{ A_{j_1} \times A_{j_2} \times \cdots \times A_{j_t} \},
\]

(79)
where \( t \) is a positive integer and \( \{A_1, A_2, \ldots, A_m\} \) is a partition of \( V \) which satisfies
\[
\bigcup_{j=1}^{m} A_j = V, \tag{80}
\]
\[
A_j \neq \emptyset \quad \text{for } j = 1, 2, \ldots, m, \tag{81}
\]
\[
A_j \cap A_{j'} = \emptyset \quad \text{if } j \neq j'. \tag{82}
\]

Proof of Theorem 12: If there exists a partition \( \{A_1, A_2, \ldots, A_m\} \) satisfying (79)–(82) for the access structure \( \Gamma \), the ideal SSS can be obtained by letting
\[
\varphi_{\Gamma}(i) = W_j^{(t)} \quad \text{if } V_i \in A_j. \tag{83}
\]
for each \( i = 1, 2, \ldots, n \). Next, we show the necessity of (79)–(82). Suppose that a certain \( \varphi_{\Gamma}(i) \) attains \( \rho_i = 1 \) for all \( i \). Then, define each \( A_j \) as
\[
A_j \overset{\text{def}}{=} \Phi_{\Gamma}^{-1}\left(\left\{W_j^{(t)}\right\}\right), \quad j = 1, 2, \ldots, m, \tag{84}
\]
for \( j = 1, 2, \ldots, m \) where \( \Phi_{\Gamma}^{-1} : 2^{W_{t,m}} \to 2^V \) is the inverse map of \( \Phi_{\Gamma}(A) \overset{\text{def}}{=} \sum_{i : V_i \in A} \varphi_{\Gamma}(i) \). Then, it is easy to see that \( A_j \)'s satisfy (79), (80) and (81). Next, we prove that \( A_j \)'s defined by (84) satisfy (82). Assume that there exist \( A_j \) and \( A_{j'} \), \( j \neq j' \), not satisfying (82). Then, there exists a share \( V_i \in A_j \cap A_{j'} \). This means that \( \varphi_{\Gamma}(i) \supset \{W_j^{(t)}, W_{j'}^{(t)}\} \), which contradicts \( \rho_i = |\varphi_{\Gamma}(i)| = 1 \). Hence, \( \{A_1, A_2, \ldots, A_m\} \) must be a partition of \( V \) satisfying (79)–(82). \( \square \)

In the case of \( t = 2 \), it is known that an access structure \( \Gamma \) can be realized by an ideal SSS if and only if \( \Gamma \) can be represented by a complete multipartite graph [16]. We note that this condition coincides with (79)–(82) in this case. Furthermore, in the case that \( |A_j| = 1 \) for \( j = 1, 2, \ldots, m \), the access structure coincides with the \( (t, m) \)-threshold access structure. Hence, if \( \Gamma \) is the \( (k, n) \)-threshold access structure, the multiple assignment maps obtained from the integer programming problems \( \text{IP}_{\hat{\rho}}(\Gamma) \) and \( \text{IP}_{\rho^*}(\Gamma) \) obviously satisfy that \( |\tilde{\varphi}_{\Gamma}(i)| = |\varphi_{\Gamma}(i)| = 1 \) for all \( i \).

We note that any access structures not satisfying (79)–(82) must have \( \hat{\rho} > 1 \) and \( \rho^* \geq 2 \) if the multiple assignment map is used. But, an access structure not satisfying (79)–(82) might be realized as an ideal SSS if we use another construction method. For example, refer [7].

In this paper, we assume that every share is significant. But, if there exist vacuous shares in the access structure \( \Gamma \), it is cumbersome to check whether each share is significant or vacuous. From Remark 1, the optimal multiple assignment map \( \tilde{\varphi}_{\Gamma} \) attaining the minimum average coding rate must satisfy that \( |\tilde{\varphi}_{\Gamma}(i)| = 0 \) for any vacuous share \( V_i \). On the other hand, it clearly holds that \( |\varphi_{\Gamma}(i)| \geq 1 \) for every significant share \( V_i \) since \( \rho_i \geq 1 \) holds for any significant share. Hence, by solving the integer programming problem \( \text{IP}_{\hat{\rho}}(\Gamma) \), we can also know whether a share is significant or vacuous.

4 Multiple Assignment Maps for Incomplete Access Structures

In the previous sections, we considered how to construct a SSS for a complete general access structure \( \Gamma = \{A_1, A_0\} \). But in practice, it may be cumbersome to specify whether each subset of \( V \) is a qualified set or a forbidden set because the number of the subsets is \( 2^n \). Hence, a method is proposed in [11] to construct a SSS for the case such that some subsets of \( V \) are not specified as qualified nor forbidden sets.
Theorem 13 ([11]) Let $\Gamma^\sharp = \{A_1^\sharp, A_0^\sharp\}$ be an incomplete access structure, which has $A_1^\sharp \cup A_0^\sharp \neq 2^V$. Then, there exists a complete access structure $\Gamma = \{A_1, A_0\}$ such that

\begin{align}
A_1^\sharp &\subseteq A_1, \quad (85) \\
A_0^\sharp &\subseteq A_0, \quad (86)
\end{align}

if and only if it holds that for any $A \in A_1^\sharp$ and $B \in A_0^\sharp$, $A \nsubseteq B$. ($\square$)

In case that (87) is satisfied, the SSS satisfying the incomplete access structure $\Gamma^\sharp = \{A_1^\sharp, A_0^\sharp\}$ can be realized by applying the cumulative map to the complete access structure $\Gamma = \{A_1, A_0\}$. In fact, for the access structure $\Gamma^\sharp = \{A_1^\sharp, A_0^\sharp\}$, a SSS is constructed in [11] by a cumulative map $\psi_{\Gamma^\sharp} (i) = \bigcup_{j \in F_j} \{W_j(i)\}$ for $A_1^\sharp = \{F_1, F_2, \ldots, F_m\}$. This construction corresponds to the case that

$$A_0^\sharp = A_0^\sharp$$

However, $\psi_{\Gamma^\sharp}$ is not efficient generally because $\psi_{\Gamma^\sharp}$ is a cumulative map, which is inefficient as described in Section 2.2. Furthermore, even if the cumulative map can attain the optimal coding rates for the access structure given by (88), the access structure may not be optimal among all the complete access structures $\Gamma = \{A_1, A_0\}$ satisfying (85) and (86) for given $\Gamma^\sharp = \{A_1^\sharp, A_0^\sharp\}$.

In our construction based on integer programming, the optimal multiple assignment map for the incomplete access structure $\Gamma^\sharp = \{A_1^\sharp, A_0^\sharp\}$ can easily be obtained by applying IP$_{\rho^*}(\Gamma)$ or IP$_{\rho^*}(\Gamma)$ directly to $\Gamma^\sharp$.

Example 14 Let us consider the following access structure $\Gamma^\sharp_3 = \{A_1^\sharp, A_0^\sharp\}$:

\begin{align}
A_1^\sharp &\equiv \{\{V_1, V_4, V_5, V_6\}, \{V_1, V_2, V_5\}, \{V_1, V_2, V_6\}, \{V_2, V_3, V_5\}, \{V_2, V_4, V_5\}\}, \\
A_0^\sharp &\equiv \{\{V_1, V_3, V_4, V_6\}, \{V_1, V_3, V_5\}, \{V_1, V_5, V_6\}, \{V_3, V_4, V_5\}, \{V_4, V_5, V_6\}, \{V_2, V_5\}\},
\end{align}

Note that $A_1^\sharp$ and $A_0^\sharp$ satisfy $A_1^\sharp \subseteq A_1$ and $A_0^\sharp \subseteq A_0$ for $\Gamma_3 = \{A_1, A_0\}$, which is defined by (65) and (66) in Example 11. Then, by solving IP$_{\tilde{\rho}}(\Gamma^\sharp_3)$, we obtain the following multiple assignment map.

\begin{align}
V_1 &= \tilde{\varphi}_{\Gamma^\sharp_3} (1) = \{W_1^{(4)}\}, \\
V_2 &= \tilde{\varphi}_{\Gamma^\sharp_3} (2) = \{W_2^{(4)}, W_3^{(4)}\}, \\
V_3 &= \tilde{\varphi}_{\Gamma^\sharp_3} (3) = \{W_4^{(4)}\}, \\
V_4 &= \tilde{\varphi}_{\Gamma^\sharp_3} (4) = \{W_4^{(4)}\}, \\
V_5 &= \tilde{\varphi}_{\Gamma^\sharp_3} (5) = \{W_5^{(4)}\}, \\
V_6 &= \tilde{\varphi}_{\Gamma^\sharp_3} (6) = \{W_6^{(4)}\},
\end{align}

where $W_i^{(4)} \in W_{(4,6)}$, and it holds that $\tilde{\rho} = 7/6$ and $\rho^* = 2$. If we apply the cumulative map to $\Gamma^\sharp_3$, $\psi_{\Gamma^\sharp_3}$ is constructed from the $(6,6)$-threshold scheme, and it has $\tilde{\rho} = 3$ and $\rho^* = 5$. ($\square$)

Similarly to the complete SSS, vacuous shares $V_i$ in $\Gamma^\sharp = \{A_1^\sharp, A_0^\sharp\}$ can be detected by checking $|\varphi_{\Gamma^\sharp}(i)| = 0$ for the solution of the IP$_{\tilde{\rho}}(\Gamma^\sharp)$. 

5 Ramp SSSs with General Access Structures

The coding rate $\rho_i$ must satisfy $\rho_i \geq 1$ for any significant share $V_i$ in the case that the access structure consists of $A_1$ and $A_0$, i.e., every subset $A \subseteq V$ is classified into either qualified sets or forbidden sets. But, in the case of ramp access structures such that some subsets of $V$ are allowed to have intermediate properties between the qualified and forbidden sets, it is possible to decrease the coding rate $\rho_i$ to less than 1. The SSSs having the ramp access structure are called ramp schemes [17, 18]. In this section, we treat the construction of ramp SSSs based on the multiple assignment maps. We consider only the minimum average coding rate in this section. But, for the minimum worst coding rate, integer programming can be formulated in a similar way.

5.1 Preliminaries for Ramp Schemes

First, let us review the definition of ramp SSSs. Suppose that $L + 1$ families $A_j \subseteq 2^V$, $j = 0, 1, \ldots, L$, satisfy the following.

$$H(S|A) = \frac{L-j}{L} H(S), \text{ for any } A \in A_j$$

Equation (97) implies that the secret $S$ leaks out from a set $A \in A_j$ with the amount of $(j/L)H(S)$. Especially, $S$ can be decrypted completely from any $A \in A_L$, and any $A \in A_0$ leaks out no information of $S$. Note that, in the case of $L = 1$, the ramp SSS reduces to the SSS treated in Sections 2–4, and hence, the ramp SSS can be considered as an extension of the ordinal SSS. To distinguish the ordinal SSSs from ramp SSSs, the ordinal SSSs are called the perfect SSSs. We call $\Gamma^R = \{A_0, A_1, \ldots, A_L\}$ the access structure of the ramp SSS with $L + 1$ levels. Without loss of generality, we can assume that $\bigcup_{j=0}^{L} A_j = 2^V$ and $A_j \cap A_{j'} = \emptyset$ for $j \neq j'$, although incomplete access structures with $\bigcup_{j=0}^{L} A_j \neq 2^V$ can be treated in the same way as in Section 4.

For example, the access structure of $(k, L, n)$-threshold ramp SSS [18, 17] is defined as follows:

$$A_0 = \{A \in 2^V : 0 \leq |A| \leq k - L\}, \quad A_j = \{A \in 2^V : |A| = k - L + j\}, \text{ for } 1 \leq j \leq L - 1,$$

$$A_L = \{A \in 2^V : k \leq |A| \leq n\}.$$ (98) (99) (100)

In ramp SSSs, a significant share can also be defined in the same way as the perfect SSSs shown in Section 2.1. A share $V_i \in V$ is called significant if there exists a share set $A \in 2^V$ such that $A \cup \{V_i\} \in A_j$ and $A \in A_{j'}$ with $j > j'$. Then, a non-significant share $V_i$ satisfies that $A \cup \{V_i\} \in A_j$ for any share set $A \in A_j$, $j = 0, 1, \ldots, L$. Furthermore, if a non-significant share $V_i$ satisfies $\{V_i\} \in A_0$, $V_i$ plays no roll in the ramp SSS, and hence, we call $V_i$ a vacuous share. However, there exists a ramp scheme such that $A_0 = \emptyset$ and a non-significant share satisfy $\{V_i\} \in A_j$ for some $j \geq 1$. This case implies that $H(V_i) \geq H(S)/L$, and $H(V_i|V) = 0$ for any $V \in V$, i.e., a non-significant $V_i$ is included in every share. Therefore, we call such a non-significant share $V_i$ a common share.

Remark 15 It is known that for any access structure with $L + 1$ levels, the coding rate $\rho_i$ must satisfy $\rho_i \geq 1/L$ for any significant share $V_i$ [19]. Especially, in the case of $(k, L, n)$-threshold SSSs, the optimal ramp SSS attaining $\rho_i = 1/L$ for all $i$ can easily be constructed [17, 18]. Any common share $V_i$ must also satisfy that $\rho_i \geq 1/L$. On the other hand, in the same way as Remark 1 for the perfect SSSs, each vacuous share $V_i$ can be realized as $\rho_i = 0$ for any access structure. Furthermore,
if there exists a vacuous share with $\rho_i > 0$, the average coding rate can be reduced by setting $\rho_i = 0$
without changing all the significant and the common shares.

Letting $\hat{A}_j \overset{\text{def}}{=} \bigcup_{\ell=1}^{L} \mathcal{A}_\ell$ and $\hat{A}_j \overset{\text{def}}{=} \bigcup_{\ell=1}^{j} \mathcal{A}_\ell$, for $j = 0, 1, \ldots, L$, the monotonicity in (3) and (4) are extended as follows:

$$A \in \hat{A}_j \Rightarrow A' \in \hat{A}_j \text{ for all } A' \supseteq A$$
(101)

$$A \in \hat{A}_j \Rightarrow A' \in \hat{A}_j \text{ for all } A' \subseteq A$$
(102)

Therefore, the minimal and maximal families of the access structure, $\Gamma^R = \{A_0^{-}, A_1^{-}, \ldots, A_L^{-}\}$ and $\Gamma^{R+} = \{A_0^{+}, A_1^{+}, \ldots, A_L^{+}\}$, respectively, can be defined as

$$\hat{A}_j^{-} = \{A \in \hat{A}_j : A - \{V\} \not\subseteq \hat{A}_j \text{ for any } V \in A\},$$
(103)

$$\hat{A}_j^{+} = \{A \in \hat{A}_j : A \cup \{V\} \not\subseteq \hat{A}_j \text{ for any } V \in 2^V - A\}. $$
(104)

Then, the following theorem holds.

**Theorem 16** ([19]) A ramp SSS with access structure $\Gamma^R = \{A_0, A_1, \ldots, A_L\}$ can be constructed if and only if $\hat{A}_j$ (or $\hat{A}_j$) satisfies the monotonicity (101) (or (102)) for all $j = 1, 2, \ldots, L$.

In Theorem 16, the necessity of the condition is obvious, and the sufficiency is established by the next construction.

**Construction 17** ([19]) Let $S = \{S^{(1)}, S^{(2)}, \ldots, S^{(L)}\}$ be a secret, and let $\Gamma^{(i)} = \{\hat{A}_j, 2^V - \hat{A}_j\}$, $j = 1, 2, \ldots, L$, be the perfect access structures determined from a given access structure $\Gamma^R$. Since each $\Gamma^{(i)}$ is a perfect access structure satisfying the monotonicity (3) and (4), we can construct a SSS with $\Gamma^{(i)}$ for secret $S^{(i)}$. Letting $\{V_1^{(i)}, V_2^{(i)}, \ldots, V_n^{(i)}\}$ be the shares for $S^{(i)}$ and $\Gamma^{(i)}$, the share $V_i = \{V_1^{(i)}, V_2^{(i)}, \ldots, V_n^{(i)}\}$ realizes the access structure $\Gamma^R$. For $\Gamma^R$, a ramp SSS can also be constructed from $\{2^V - \hat{A}_j, \hat{A}_j\}$ instead of $\Gamma^{(i)} = \{2^V - \hat{A}_j, \hat{A}_j\}$.

**Remark 18** Note that in Construction 17, we have $\rho_i \geq 1$ for any access structure. For example, in the case that Construction 17 is applied to the $(k, L, n)$-threshold access structure, the constructed ramp SSS has $\rho_i = 1$ although the $(k, L, n)$-threshold SSS can be realized with $\rho_i = 1/L$. Therefore, Construction 17 is not efficient generally.

**Example 19** Consider the following ramp access structure $\Gamma^R$ for $V = \{V_1, V_2, V_3, V_4\}$:

$$\mathcal{A}_3 = \{\{V_1, V_2, V_3, V_4\}\},$$
(105)

$$\mathcal{A}_2 = \{\{V_1, V_2, V_3\}, \{V_1, V_3, V_4\}\},$$
(106)

$$\mathcal{A}_1 = \{\{V_1, V_2, V_4\}, \{V_2, V_3, V_4\}\},$$
(107)

$$\mathcal{A}_0 = \{A : 0 \leq |A| \leq 2\}.$$
(108)

First, we derive the access structures $\Gamma^{(1)}, \Gamma^{(2)},$ and $\Gamma^{(3)}$ based on (105)–(108), and it is easy to see that $\Gamma^{(1)}$ and $\Gamma^{(3)}$ become $(3, 4)$- and $(4, 4)$-threshold access structures, respectively. Hence, we have $V_i^{(1)} = W_i^{(3)}$ and $V_i^{(3)} = W_i^{(4)}$ for $i = 1, 2, 3, 4$ where $\{W_i^{(3)}\}_{i=1}^{4}$ and $\{W_i^{(4)}\}_{i=1}^{4}$ are the share sets of $(3, 4)$- and $(4, 4)$-threshold access structures for secrets $S^{(1)}$ and $S^{(3)}$, respectively. Furthermore, a perfect SSS with the access structure $\Gamma^{(2)}$ for a secret $S^{(2)}$ can be realized by $\{V_i^{(2)}\}_{i=1}^{4}$ such that
$V_1^{(2)} = W_1^{(3)}$, $V_2^{(2)} = W_2^{(3)}$, $V_3^{(2)} = W_3^{(3)}$, and $V_4^{(2)} = W_2^{(3)}$ where $\{W_i^{(3)}\}_{i=1}^3$ is the share sets of $(3,3)$-threshold SSS for $S^{(2)}$.

According to Construction 17, we can obtain the shares such that $V_1 = \{W_1^{(3)}, W_1^{r(3)}, W_1^{(4)}\}$, $V_2 = \{W_2^{(3)}, W_2^{r(3)}, W_2^{(4)}\}$, $V_3 = \{W_3^{(3)}, W_3^{r(3)}, W_3^{(4)}\}$, $V_4 = \{W_4^{r(3)}, W_4^{(3)}, W_4^{(4)}\}$. Since each share consists of three primitive shares for three secrets $S^{(1)}$, $S^{(2)}$, $S^{(3)}$, the constructed ramp SSS has $\tilde{\rho} = \rho^* = 1$.

The construction of ramp SSSs for general access structures are treated in [20]. But, since the construction in [20] is based on monotone span programming, it is much complicated compared with the multiple assignment map.

### 5.2 Optimal Multiple Assignment Maps for Ramp SSSs

First, let $W_{(t,L,m)} = \{W_1^{(t,L)}, W_2^{(t,L)}, \ldots, W_m^{(t,L)}\}$ be the set of primitive shares for the $(t, L, m)$-threshold ramp SSS with the coding rate $\rho_t = 1/L$. Then, defining $y$ and $a(\ell; A)$ in the same way as the perfect SSSs in Section 3, the optimal ramp SSS by the multiple assignment map for a general access structure $\Gamma^R$ can be obtained by solving the following integer programming problem:

\[
\begin{align*}
\text{minimize} & \quad h \cdot y^T \\
\text{subject to} & \quad a(-1; A) \cdot y^T \geq 0 \quad \text{for} \quad A \in A_L^- \\
& \quad -a(-1; A) \cdot y^T = j \quad \text{for} \quad A \in A_j^+ \cup A_j^- \quad \text{for} \quad 1 \leq j \leq L - 1 \\
& \quad -a(-1; A) \cdot y^T \geq L \quad \text{for} \quad A \in A_0^+ \\
& \quad y \geq 0
\end{align*}
\]

**Remark 20** From the monotonicity defined in (101) and (102), it is sufficient to consider only $A \in A_j^+ \cup A_j^-$ instead of all $A \in A_j$ on the marked line $(\ast)$ in $\text{IP}_{\tilde{\rho}}^R (\Gamma^R)$. Note that the same primitive shares may be distributed to all shares since there may exist common shares in ramp SSSs. Hence, we may have $x_N \neq 0$ in the ramp SSSs although we can always assume that $x_N = 0$ in the perfect SSSs.

From Remark 15, significant or common shares $V_i$ must satisfy that $|\phi_T(i)| \geq 1$ for any multiple assignment map $\phi_T$. On the other hand, $|\phi_T(i')| = 0$ must hold for vacuous shares $V_{i'}$ for the optimal multiple assignment map $\phi_T$ attaining the minimal average coding rate. Hence, it suffices to consider only significant shares and common shares in the ramp SSSs.

**Example 21** If the access structures $\Gamma_4^R$ in Example 19 is applied to the integer programming problem $\text{IP}_{\tilde{\rho}}^R (\Gamma_4^R)$, the following multiple assignment map is obtained

\[
\begin{align*}
V_1 = \tilde{\phi}_{\Gamma_4^R}(1) &= \{W_1^{(7,3)}, W_2^{(7,3)}\}, \\
V_2 = \tilde{\phi}_{\Gamma_3^R}(2) &= \{W_3^{(7,3)}, W_4^{(7,3)}\}, \\
V_3 = \tilde{\phi}_{\Gamma_4^R}(3) &= \{W_5^{(7,3)}, W_6^{(7,3)}\}, \\
V_4 = \tilde{\phi}_{\Gamma_4^R}(4) &= \{W_7^{(7,3)}, W_7^{(7,3)}\}
\end{align*}
\]

where $W_i^{(7,3)} \in W_{(7,3,7)}$, $\tilde{\phi}_{\Gamma_4^R}$ attains that $\tilde{\rho} = \rho^* = 2/3$.

□
Note that the coding rates less than 1 cannot be achieved by Construction 17. Furthermore, our construction is much simpler compared with the method in [20]. But, unfortunately, the integer programming problem may not have any feasible solutions in the case of ramp SSSs.

**Example 22** The following access structure \( \Gamma_5^R \) cannot be constructed by any multiple assignment map since the corresponding integer programming problem has no feasible solution.

\[
\begin{align*}
A_4^- &= \{ \{V_1, V_2, V_3, V_4\}, \{V_1, V_2, V_4, V_5\}, \{V_2, V_3, V_4, V_5\}\}, \\
A_3 &= \{ \{V_1, V_2, V_3, V_5\}, \{V_1, V_3, V_4, V_5\}, \{V_1, V_2, V_4, V_5\}, \{V_1, V_2, V_3, V_4\}, \{V_1, V_3, V_4\}, \{V_1, V_3, V_5\}, \{V_3, V_4, V_5\}, \{V_1, V_5\}, \{V_1, V_3\}, \{V_1, V_4\}, \{V_1, V_5\}\}, \\
A_2 &= \{ \{V_1, V_2, V_3\}, \{V_1, V_2, V_4\}, \{V_1, V_2, V_5\}, \{V_2, V_3, V_5\}, \{V_2, V_4, V_5\}, \{V_3, V_4, V_5\}, \{V_1, V_3, V_5\}, \{V_1, V_4, V_5\}, \{V_1, V_5\}\}, \\
A_1 &= \{ \{V_1, V_2\}, \{V_1, V_3\}, \{V_2, V_3\}, \{V_3, V_4\}\}, \\
A_0^+ &= \{ \{V_1, V_4\}, \{V_2, V_5\}, \{V_3, V_5\}\}, \\
\end{align*}
\]

(113)\( \quad \text{(113)} \)

(114)\( \quad \text{(114)} \)

(115)\( \quad \text{(115)} \)

(116)\( \quad \text{(116)} \)

(117)\( \quad \text{(117)} \)

\[ H(S|A) = 0, \quad \text{for all } A \in A_L, \]  
\[ H(S|A) \geq \frac{L-j}{L} H(S), \quad \text{for all } A \in A_j, \quad 1 \leq j \leq L-1, \]  
\[ H(S|A) = H(S), \quad \text{for all } A \in A_0. \]  

(118)\( \quad \text{(118)} \)

(119)\( \quad \text{(119)} \)

(120)\( \quad \text{(120)} \)

In this case, we can modify the definition of the ramp SSS given by (97) as follows.

\[ H(S|A) = 0, \quad \text{for all } A \in A_L, \]  
\[ H(S|A) \geq \frac{L-j}{L} H(S), \quad \text{for all } A \in A_j, \quad 1 \leq j \leq L-1, \]  
\[ H(S|A) = H(S), \quad \text{for all } A \in A_0. \]  

(118)\( \quad \text{(118)} \)

(119)\( \quad \text{(119)} \)

(120)\( \quad \text{(120)} \)

In order to implement (118)–(120) in the integer programming, it suffices to replace the marked line (\( \ast \)) in IP\(_{\tilde{\rho}}^R (\Gamma^R)\) by \(-a(-1; A_j) \cdot y^T \geq j\). Letting IP\(_{\tilde{\rho}}^{R2} (\Gamma^R)\) be the modified integer programming problem, the next theorem holds.

**Theorem 23** The integer programming problem IP\(_{\tilde{\rho}}^{R2} (\Gamma^R)\) always has a feasible solution for any access structure \( \Gamma^R \).

\[ \square \]

**Proof of Theorem 23:** Let \( V \) be a multiset in \( 2^V \), some elements of which may be the same. Then, for \( V \) and \( A \subseteq V \), we define \( N(V, A) \) as follows.

\[ N(V, A) = |\{ A' \in V : A \subseteq A' \}|, \]  

(121)\( \quad \text{(121)} \)

where all \( A' \in V \) are treated as different sets even if some of them are the same. Now we construct a multiset \( U \) for \( \Gamma^R = \{ A_0, A_1, \ldots, A_L \} \) by the next construction.

**Construction 24**

(1) Let \( U := \emptyset \) and \( j := 1 \).

(2) For each \( A \in A_{L-j}^+ \) satisfying \( N(U, A) < j \), we add \( A \) into \( U \), \( (j - N(U, A)) \) times.

(3) Let \( j := j + 1 \).

(4) If \( j < L \), go to (2). In case of \( j = L \), go to (5).

(5) Output \( U \).

\[ \square \]
From the monotonicity of $\tilde{A}_j$ in (101), the family $\mathcal{U}$ can always be constructed. Then, letting $\mathcal{U} = \{F_1, F_2, \ldots, F_m\}$, we can define a map $\tilde{\psi}: \{1, 2, \ldots, n\} \rightarrow 2^{W_{(m,L,m)}}$ by

$$\tilde{\psi}(i) = \bigcup_{j: V_i \not\in F_j} \left\{ W_j^{(m,L)} \right\},$$

(122)

where $W_j^{(m,L)} \in W_{(m,L,m)}$. Note that in the case of $L = 1$, (122) coincides with the cumulative map in (17). Furthermore, for any set $F_\ell \in \mathcal{U}$, we can check from (122) that

$$W_\ell^{(m,L)} \not\subseteq \bigcup_{i: V_i \in F_\ell} \tilde{\psi}(i),$$

(123)

holds for all $\ell'$ satisfying $F_\ell \subseteq F_{\ell'}$.

Now, assume that $F_\ell \in A_j^+$. Then, from Construction 24, there exist a family of $j$ subsets $\{F_{\ell_1}, F_{\ell_2}, \ldots, F_{\ell_j}\} \subseteq \mathcal{U}$ satisfying $F_\ell \subseteq F_{\ell'}$ for $\ell' \in \{\ell_1, \ell_2, \ldots, \ell_j\}$. Hence, it holds from (123) that $W_\ell^{(m,L)} \not\subseteq \bigcup_{i: V_i \in F_\ell} \tilde{\psi}(i)$ for $\ell' \in \{\ell_1, \ell_2, \ldots, \ell_j\}$. This means that we can verify that $\left| \bigcup_{i: V_i \in F_\ell} \tilde{\psi}(i) \right| \leq m - j$, and $V_i = \tilde{\psi}(i)$ satisfies (118)–(120). Therefore, $\text{IP}^R_{\tilde{\rho}} (\Gamma^R)$ always has at least one feasible solution. \hfill \Box

Note that as shown in the following example, Construction 24 gives inefficient assignments of the primitive shares, generally.

**Example 25** Assume that the access structure $\Gamma^R_0$ in (113)–(117) satisfies the conditions (118)–(120). First, we apply Construction 24 to the access structure $\Gamma^R_0$. Then, we obtain the following multiset $\mathcal{U}_{\Gamma^R_0}$.

$$\mathcal{U}_{\Gamma^R_0} = \{V_1, V_2, V_3, V_5\}, \{V_1, V_3, V_4, V_5\}, \{V_1, V_2, V_4\}, \{V_1, V_2, V_5\}, \{V_1, V_4, V_5\}, \{V_2, V_3, V_5\}, \{V_2, V_3, V_4\}, \{V_2, V_4, V_5\}, \{V_3, V_4, V_5\}, \{V_1, V_4\}. \quad (124)$$

Hence, we can obtain $V_i = \tilde{\psi}(i)$, $i = 1, 2, \ldots, 5$, as follows:

$$V_1 = \tilde{\psi}(1) = \left\{ W_6^{(11,4)}, W_7^{(11,4)}, W_8^{(11,4)}, W_9^{(11,4)}, W_{10}^{(11,4)} \right\},$$

(125)

$$V_2 = \tilde{\psi}(2) = \left\{ W_2^{(11,4)}, W_5^{(11,4)}, W_9^{(11,4)}, W_{11}^{(11,4)} \right\},$$

(126)

$$V_3 = \tilde{\psi}(3) = \left\{ W_3^{(11,4)}, W_4^{(11,4)}, W_5^{(11,4)}, W_6^{(11,4)}, W_9^{(11,4)}, W_{11}^{(11,4)} \right\},$$

(127)

$$V_4 = \tilde{\psi}(4) = \left\{ W_1^{(11,4)}, W_4^{(11,4)}, W_6^{(11,4)} \right\},$$

(128)

$$V_5 = \tilde{\psi}(5) = \left\{ W_3^{(11,4)}, W_7^{(11,4)}, W_8^{(11,4)} \right\},$$

(129)

where $W_i \in W_{(11,4,11)}$. In this case, we have $\tilde{\rho} = 21/20$ and $\rho^* = 3/2$ since it holds that $H(W_i^{(11,4)}) = H(S)/4$ for each $i$.

On the other hand, we can construct the following optimal multiple assignment map $\tilde{\varphi}_{\Gamma^R_0}$ by solving
the integer programming problem $\text{IP}^{R^2}_{\tilde{\rho}}(\Gamma^R_5)$.

\begin{align}
V_1 &= \tilde{\varphi}_{\Gamma^R_5}(1) = \left\{ W^{(8,4)}_1, W^{(8,4)}_2 \right\}, \\
V_2 &= \tilde{\varphi}_{\Gamma^R_5}(2) = \left\{ W^{(8,4)}_3, W^{(8,4)}_4, W^{(8,4)}_5 \right\}, \\
V_3 &= \tilde{\varphi}_{\Gamma^R_5}(3) = \left\{ W^{(8,4)}_2, W^{(8,4)}_6 \right\}, \\
V_4 &= \tilde{\varphi}_{\Gamma^R_5}(4) = \left\{ W^{(8,4)}_7, W^{(8,4)}_8 \right\}, \\
V_5 &= \tilde{\varphi}_{\Gamma^R_5}(5) = \left\{ W^{(8,4)}_9 \right\},
\end{align}

where $W^{(8,4)}_i \in W_{(8,4,9)}$, and it holds that $\tilde{\rho} = 1/2$ and $\rho^* = 3/4$, which are more efficient than the rates of Construction 24. Note that (125)–(129) and (130)–(134) do not satisfy (97) but satisfy (118)–(120). For instance, in (130)–(134), it holds for $\{V_1, V_5\} \in \mathcal{A}_2$ that $H(S\mid\{V_1, V_5\}) = H(S) > H(S)/2$.

Finally, we compare Construction 17 with Construction 24 for the access structure $\Gamma^R_5$. If we use the cumulative map to realize each perfect SSS with the access structure $\Gamma^{(j)}_5$, $j = 1, 2, 3, 4$, in Construction 17, we obtain $\tilde{\rho} = 9/5$ and $\rho^* = 2$. Hence, Construction 17 is more inefficient than Construction 24 in this case.

\section{Conclusion}

We proposed a method to construct SSSs for any given general access structures based on $(t,m)$-threshold SSSs and integer programming. The proposed method can attain the optimal average and/or worst coding rates in the sense of multiple assignment maps. Hence, the proposed method can attain smaller coding rates compared with the cumulative maps and the modified cumulative maps. Furthermore, the proposed method can be applied to incomplete and/or ramp access structures in addition to complete and perfect access structures.
