ABSTRACT
Xeroderma pigmentosum (XP) involves a defect in the initial step of nucleotide excision repair (NER) and consists of eight genetic complementation groups (groups A–G and a variant). XP group A (XPA) patients have a high incidence of UV-induced skin tumors, immature testicular development, and neurological symptoms. In an earlier study, we have shown that XP group A (Xpa) gene-knockout mice (Xpa−/− mice) were highly sensitive to UV-induced skin carcinogenesis with a defect in NER and were highly susceptibility to spontaneous tumorigenesis with impaired spermatogenesis. However, the pathology of impaired spermatogenesis in Xpa−/− mice is unknown. To unravel the underlying pathology, we made a concerted effort using the testis of 3-month-old Xpa−/− mice. We found many large vacuoles in the seminiferous tubules of 3-month old Xpa−/− mice, while there were no large vacuoles in that of Xpa+/+ mice. Immunohistochemistry of microtubule-associated protein 1 light chain 3 (LC3), an autophagosome marker, showed degenerating cells with intense signal of LC3 in the seminiferous tubules, and immunoblotting revealed induction of LC3-II in the 3-month-old Xpa−/− mice. The results of the present study suggest autophagy induction as the possible mechanism underlying the impaired spermatogenesis in Xpa−/− mice. Therefore, Xpa−/− mice could be a useful model for investigating aging and male infertility with low expression of XPA.

INTRODUCTION
Xeroderma pigmentosum (XP) is an autosomal recessive disease marked by an extreme hypersensitivity to sunlight, susceptibility to skin cancer in sun-exposed areas, and severe neurological abnormalities. Cells from XP patients show hypersensitivity to killing by UV-irradiation. In addition to these symptoms, XP group A patients have immature testicular development. There are eight genetic complementation groups in XP; XP group A through XP group G and a variant (XPV). The primary defect in XP group A (XPA) through XP group G (XPG) ascribes in an early step of nucleotide excision repair (NER) whereas XPV has a normal NER process but a defect in translesion DNA synthesis. In the NER, XPA protein has a role in the verification of abnormalities in DNA chemistry with the helicase activity of transcription factor II H (TFIIH). To date, the genes responsible for NER and translesion synthesis associated with XP have been identified (XPA–XPG and XPV, respectively), and core NER reactions have been reconstituted using purified proteins including XPA–XPG proteins (DeSanctis and Cacchione 1932; Friedberg et al. 2006; Sugasawa 2016).

We have generated Xpa gene-knockout mice (Xpa−/− mice) by insertion of the neo gene into exon 4 of the mouse Xpa gene. The Xpa−/− mice were found to
be defective in NER and highly susceptible to ultraviolet-B(UVB)- or 9,10-dimethyl-1,2-benz[a]anthracene (DMBA)-induced skin carcinogenesis, therefore presenting as a suitable animal model to study the UVB-induced skin tumorigenesis in XP group A patients (Nakane et al. 1995). In another study using the Xpa<sup>−/−</sup> mice, we reported impairment of spermatogenesis with reduction of testis weight in an age-dependent manner and higher incidence of spontaneous tumorigenesis later in life. The relative weight ratio of the testis in the Xpa<sup>−/−</sup> mice was reduced to 87.5 percent of that in the Xpa<sup>+/+</sup> mice at 3 months old, half of that in the Xpa<sup>−/−</sup> mice at 12 months old and finally one-third of that in the Xpa<sup>−/−</sup> mice at 24 months old. Male Xpa<sup>−/−</sup> mice were fertile until about 30 weeks of age. We found degenerating seminiferous tubules in the testes of Xpa<sup>−/−</sup> mice after 6 months of age. The degenerating seminiferous tubules were detected in a few percent of tubules at 6 months of Xpa<sup>−/−</sup> mice, half of tubules at 12 months of Xpa<sup>−/−</sup> mice, and all tubules at 24 months of Xpa<sup>−/−</sup> mice. In contrast, there were no degenerating seminiferous tubules in the Xpa<sup>−/−</sup> mice at the age of 3 months (Nakane et al. 2008). We supposed that the endogenous DNA damages such as cyclopurine repaired by only NER might affect the relatively short time course of impaired spermatogenesis in the Xpa<sup>−/−</sup> mice (Nakane et al. 2008; Brooks 2017). Recently, we detected a higher accumulation of oxidatively generated type of DNA damage called purine 8,5'-cyclo-2'-deoxynucleoside (cyclopurine) in their organs of 1-, 3-, 6-, 24-month-old Xpa<sup>−/−</sup> mice than in those of wild type (wt) mice (Mori et al. 2019). Moreover, it has been reported that abnormalities in DNA repair are associated with male infertility (Gunes et al. 2015; Nagirnaja et al. 2018). However, the pathology of testicular degeneration of Xpa<sup>−/−</sup> mice remains unknown.

To maintain cellular homeostasis, autophagy is an intracellular degradation pathway, through which a portion of the cytoplasm is brought to lysosomes to be degraded and is stimulated in response to some stressful situations such as nutrient deprivation, oxidative stress, and DNA damage. Microtubule-associated protein 1 light chain 3 (LC3) is a ubiquitin-like protein and is initially synthesized as LC3-I (approximately 16–18 kDa), and then modified into the phosphatidylethanolamine (PE)-conjugated form, LC3-II on the surface of newly formed autophagosomes (Gomes et al. 2017; Yoshii and Mizushima 2017). Therefore, the level of LC3-II or the conversion of LC3-I to LC3-II are the most widely used peculiar markers associated with completed autophagosomes. XPA deficiency upregulates autophagy with mitochondrial dysfunction in XP group A patient’s cells (Fang et al. 2014); XPA protein might affect mitochondrial maintenance and regulation of mitophagy (Manandhar et al. 2017). Besides, a study has also reported the induction of autophagy in NER-deficient mice (Marino et al. 2008). Based on the studies reporting impaired spermatogenesis and autophagy induction in the Xpa<sup>−/−</sup> mice, we hypothesized that autophagy could be involved in the impaired spermatogenesis in Xpa<sup>−/−</sup> mice.

Here, to elucidate the pathology of testicular degeneration in Xpa deficiency, we investigated the testis of 3-month-old Xpa<sup>−/−</sup> mice compared to that of wt mice through immunohistochemistry and immunoblotting with anti-LC3 antibody. These findings suggest a novel role of autophagy in the testicular degeneration of the Xpa<sup>−/−</sup> mice.

MATERIALS AND METHODS

**Mutant mice.** The Xpa gene-knockout mice (Xpa<sup>−/−</sup> mice) were generated by the insertion of the neo gene into the exon 4 of mouse Xpa gene and had a chimeric genetic background of CBA/C57BL6/CD-1 (Nakane et al. 1995). The mice were kept under specific pathogen-free conditions, housed in a controlled environment at 20–26°C, fed a CE-2 diet (Clea Japan Inc, Tokyo, Japan) and sterilized water ad libitum for an extended period. All animal experiments in this study were conducted following the guidelines for the institutional animal care and use committee (No.18-Y-13) and the safety committee for genetic recombination experiments (No.28-017) of Tottori University.

**Tissue preparation.** Three-month-old animals were deeply anesthetized under triple mixed anesthesia (medetomidine, midazolam and butorphanol). Testes were fixed overnight in Bouin’s solution and then transferred to 70% ethanol. Mice were transcardially perfused with 4% paraformaldehyde (PFA) in 0.1 M phosphate buffered saline (PBS) for immunohistochemistry. These organs were embedded in paraffin. Paraffin sections 3-μm-thick were prepared and stained with periodic acid-Schiff and hematoxylin (PAS/H). Cover-slipped sections were viewed, and the images were captured using a Nikon Eclipse E600 microscope (Nikon, Tokyo, Japan). To check the number of seminiferous tubules with large vacuoles (loss of several to many cells) (Fig. 1B, inset lower square), we observed 250 seminiferous tubules of each testis (7 control mice and 7 Xpa<sup>−/−</sup> mice).
Data on all pathological and immunohistochemical changes were obtained from at least three mice. For the immunoblotting of mouse testis, freshly removed mouse testes were weighed and frozen with liquid nitrogen and stored at −80°C until the further experiment.

**Protein extraction and immunoblotting.** All the procedures were carried out at 4°C. Tissues were lysed by sonication in 10 mM Tris-HCl (pH 7.4), 150 mM NaCl, 1 mM EDTA, 1 mM EGTA, 1% Triton X-100 and a protease inhibitor cocktail (Roche Diagnostics, Indianapolis, IN). The supernatants were centrifuged at 100,000 × g for 30 min, and the insoluble pellets were suspended in the same extraction buffer. Protein concentrations were determined using the Protein Assay Rapid Kit (WAKO, Tokyo, Japan). Immunoblotting was performed with rabbit polyclonal anti-LC3 Ab (MBL, Nagoya, Japan), and polyclonal anti-tubulin Ab (Santa Cruz Biotech, Santa Cruz, CA). Immuno-positive signals were visualized by ECL plus reagent (GE Healthcare, Buckinghamshire, UK), and images were obtained using LAS-4000 image analyzer (Fujifilm, Tokyo, Japan) (Takai et al. 2013).

**Immunohistochemistry for LC3.** LC3 immunohistochemistry was done with anti-LC3 Ab (microtubule-associated protein 1 light chain 3; MBL) at a dilution of 1/500 by antigen retrieval, Immunosaver (Nisshin EM, Tokyo, Japan). The Histofine SAB-PO(R) Kit (Nichirei, Tokyo, Japan) was used for visualization of primary antibody binding. Sections were counterstained with hematoxylin.

**Statistical analysis.** All experimental data are reported as mean, and the error bars represent the standard deviation (SD). Statistical analysis was performed using the Unpaired Student’s t-test. All the statistical analyses were performed using the KaleidaGraph v. 4.1.0 (Synergy software, Inc.).

**RESULTS**

**Vacuolar formation in the testis of 3-month-old Xpa−/− mice**

Careful examination of the testis of Xpa−/− mice revealed disorganization of a substantial portion of the tubule structure with large vacuoles (Fig. 1B, inset, lower square) and small vacuoles (Fig. 1B, inset, upper square) in the testis of 3-month-old Xpa−/− mice, wherein the Xpa+ mice had normal seminiferous tubules (Fig. 1A and B). The vacuoles were found to be distributed from the middle to the basal part of the seminiferous epithelium. Histological analysis revealed that the testis of Xpa−/− mice had a lot of seminiferous tubules with large vacuoles, while the testicular seminiferous tubules of wt mice had no large vacuoles (Fig. 1C). Small vacuoles were observed in the Xpa−/− and Xpa+/+ mice. The formation of large vacuoles in the testis of 3-month-old Xpa−/− mice indicated an early pathological change of impaired spermatogenesis.

**Increased number of degenerating cells with LC3 signals in the testis of 3-month-old Xpa−/− mice**

The immunohistochemistry analysis using anti-LC3 antibodies revealed the relationship between vacuole formation and the distribution of autophagy induction in the testis of Xpa−/− mice. The number of punctate LC3 structures (empty arrow head) detected in wt mice (Fig. 2A) were lower than those in the Xpa−/− mice testis (Fig. 2B and C). Besides, degenerating cells with higher signals of LC3 corresponding to the vacuole position were observed (Fig. 2B and C, black arrow), indicating increased autophagy. Judging from the location of the vacuoles, these degenerating cells with signals of LC3 on the whole cells may be the spermatogonia or primary spermatocytes. Furthermore, the measurement of body weight revealed that the caloric intake was normal in Xpa−/− mice, thereby excluding malnutrition as a cause for the observed autophagy induction in Xpa−/− mice. The results supported the assumption that vacuolar formation with reduction of testis weight might be due to autophagy induction in the testis of Xpa−/− mice.

**Autophagy induction in the testis of 3-month-old Xpa−/− mice**

To confirm the autophagy induction in the testis of 3-month-old Xpa−/− mice, we evaluated the autophagic status by immunoblot analysis using anti-LC3 antibodies. We detected the increased levels of LC3-II recruited to autophagosomal membranes only in the testis of 3-month-old Xpa−/− mice, whereas there was no LC3-II band for the testis of wt mice.

In contrast to LC3-II, cytosolic LC3-I band was unchanged both Xpa−/− mice and wt mice (Fig. 3A). The autophagic activity in the testis from 3-month-old Xpa−/− mice was significantly higher than that observed in wt mice, as assessed by the increased LC3-II/LC3-I ratio in Xpa−/− mice tissues (Unpaired Student’s t-test: P < 0.05) (Fig. 3B). The results supported the immunohistochemical results of LC3 (Fig. 2), indicating that the induction of autophagy

(B) The testis of 3-months-old Xpa\(^{-/-}\) mice. Microscopic view of seminiferous tubules; the (▵) empty arrowhead indicates a large vacuole formed by the loss of several to many cells. The insets show higher-magnification images of the area captured by the squares (lower square: large vacuole, upper square: small vacuole). Bars: 100 μm (A, B), 25 μm (inset). (C) Percentage of the number of seminiferous tubules with vacuoles observed in the testis of 3-month-old wt (Xpa\(^{+/+}\)) and Xpa\(^{-/-}\) mice. The error bar represents the standard deviation (SD). Periodic acid-Schiff and hematoxylin (PAS/H) stain.

**Fig. 2** Level of LC3 signals in the testis of 3-month-old wt and Xpa\(^{-/-}\) mice. Empty arrow heads indicate LC3 signal. (A) Testis of Xpa\(^{+/+}\) mice. (B, C) Testis of Xpa\(^{-/-}\) mice with testicular cells having signals of LC3. Arrows of (B) represent the basal cells with LC3 signals and arrows of (C) represent the cells with LC3 signals corresponding to vacuoles of the seminiferous epithelium in Xpa\(^{-/-}\) mice. The bar corresponds to 10 μm. Asterisk: large vacuole.
with loss of testicular cells could be a specific alteration caused by \textit{Xpa} deficiency.

**DISCUSSION**

The present study was carried out to understand the pathology underlying the impaired spermatogenesis in 3-month-old \textit{Xpa}-deficient mice. The histochemical and immunoblot analyses revealed the presence of a higher number of large vacuoles with induced autophagy and increased levels of LC3-II/LC3-I ratio, important biomarkers of autophagy as compared to that in the wt mice. Here, we discuss the possible mechanistic explanations for these observations.

*Nucleotide excision repair (NER) deficiency and autophagy*

There are some reports that NER deficiency is associated with autophagy. One study has reported that \textit{XPA} deficiency upregulates autophagy, leading to mitochondrial and mitophagy dysfunction in the cells of XP group A patients (Fang et al. 2014). Another study has also reported the induction of autophagy in premature aging NER-deficient mice (Marino et al. 2008). Moreover, the \textit{Xpa}\textsuperscript{−/−} mice exhibited aging phenotypes such as impairment of spermatogenesis and higher incidence of spontaneous tumorigenesis (Nakane et al. 2008). Although we obtained similar results of induced autophagy in the testis compared to that in control through immunohistochemistry and immunoblotting assays in the liver of 3-month old \textit{Xpa}\textsuperscript{−/−} mice, organ weight of the liver was not reduced (data not shown). Even if the same NER is deficient, the biological reaction may differ depending on the tissue. It can be concluded that NER deficiency in humans and mice induce autophagy.

**Mechanisms of testicular abnormalities in \textit{Xpa}\textsuperscript{−/−} mice**

In seminiferous tubules of 3-month-old \textit{Xpa}\textsuperscript{−/−} mice, we observed many large vacuoles and degenerating cells with a higher level of LC3 signals. A study involving the autophagy-related gene 7 (Atg7)-knockout infertile male mice reported the similar appearance of many large vacuoles in the seminiferous tubules which might originate from the dead germ cells compared to that in control mice (Wang et al. 2014). The appearance of large vacuoles can be considered as an early pathological change in the testis of 3-month-old \textit{Xpa}\textsuperscript{−/−} mice. In our study, we detected a higher accumulation of cyclopurine in the brain, kidney, liver, and testis of 1-, 3-, 6-, 24-month-old \textit{Xpa}\textsuperscript{−/−} mice as compared to that in wt mice in age-dependent manner. This suggested that age-dependent accumulation of endogenous cyclopurine in the brain may be critical for neurological abnormalities of XP patients. Cyclopurine lesions appeared to accumulate in DNAs of the testis from 3-month-old \textit{Xpa}\textsuperscript{−/−} mice (Mori et al. 2019). Therefore, the formation of large vacuoles in the testis of 3-month-old \textit{Xpa}\textsuperscript{−/−} mice could be attributed to the fact that the germ cells grow and differentiate continuously, and cyclopurine might be a stable block to tran-
scription and replication in rapidly proliferating cells, thus inducing autophagy or cell death of the affected testicular cells leading to the formation of large vacuoles.

Male infertility and decreased expression of XPA

It has been shown that XPA deficiency is associated with male infertility as evident from the study carried out in humans, which showed a decreased expression of XPA in 143 of the 620 infertile men with a unique polymorphism in the promoter region of XPA gene and also sperm DNA damages (Gu et al. 2010). Singh et al. (2019) reported that some azoospermic infertile patients with hypospermatogenesis and maturation arrest showed the low expression of XPA. Thus, decreased expression of XPA in testis may be associated with male infertility.

We acknowledge that there are several limitations to this study. Firstly, we do not detect the status of autophagy such as autophagy flux, indicator of autophagic activity *in vivo*. Secondly, we do not reveal the cause and the cell type of induced autophagy in the Xpa null mice. To overcome these limits, we will examine the autophagy flux and the stage specific germ cell marker on degenerating cells and monitor DNA lesion levels in testicular cells of Xpa null mice. In summary, we propose autophagy induction in the testis of 3-month-old Xpa null mice as the underlying mechanism for impaired spermatogenesis. The Xpa null mice could be a valuable animal model to study pathological processes that affect human XP patients and male infertile patients with decreased expression of XPA. We believe that the present findings provide new insight into the mechanism of male infertility and will contribute to therapy for male infertility.

CONFLICT OF INTERESTS

The authors declare that there are no conflicts of interest.

Acknowledgments

The authors thank Dr. Kiyoji Tanaka for Xpa mice. We thank Dr. Philip J. Brooks (NIH) for critical reading of the manuscript and helpful discussions. This work was supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Culture, Sports, Science and Technology of Japan (JSPS KAKENHI Grant Numbers: JP19K09671, JP26462460, JP23592379 to H.N.). We thank Mr. Toshio Kameie for his excellent technical support. We would like to thank Editage (www.editage.com) for English language editing.
