CONSIDERATIONS ON THE SUBGROUP COMMUTATIVITY DEGREE AND RELATED NOTIONS

FRANCESCO G. RUSSO

Abstract. The concept of subgroup commutativity degree of a finite group $G$ is arising interest in several areas of group theory in the last years, since it gives a measure of the probability that a randomly picked pair $(H, K)$ of subgroups of $G$ satisfies the condition $HK = KH$. In this paper, a stronger notion is studied and relations with the commutativity degree are found.

1. Introduction

In the present paper we deal only with finite group, even if there is a recent interest to the subject in the context of infinite groups [11, 10, 17, 25]. The commutativity degree of a group $G$, given by

\begin{equation}
\begin{aligned}
d(G) &= \frac{|\{(x, y) \in G \times G \mid [x, y] = 1\}|}{|G|^2} = \frac{1}{|G|^2} \sum_{x \in G} |\{y \in G \mid y^{-1} xy = x\}| \\
&= \frac{1}{|G|^2} \sum_{x \in G} |C_G(x)|,
\end{aligned}
\end{equation}

was studied extensively in [2, 4, 6, 9, 12, 16, 18, 19, 20, 21, 22, 23, 26] and generalized in various ways. Its importance is testified in the theory of the groups of prime power orders in [5, Chapter 2], where it is called measure of commutativity by Y. Berkovich in order to emphasize the fact that it really gives a measure of how far is the group from being abelian. In [7, 8, 9] it was introduced the following variation,

\begin{equation}
\begin{aligned}
d(H, K) &= \frac{|\{(h, k) \in H \times K \mid [h, k] = 1\}|}{|H||K|} = \frac{1}{|H||K|} \sum_{h \in H} |C_K(h)|,
\end{aligned}
\end{equation}

where $H$ and $K$ are two arbitrary subgroups of $G$. Of course, $d(G, G) = d(G)$, whenever $H = K = G$, and, consequently, the bounds known in literature for $d(G)$ may be sharpened by examining $d(H, K)$. In recent years, there is an increasing interest in studying the problem from the point of view of the lattice theory (see [13, 14, 15, 27, 28]). Tarnăuceanu [30, 31] has introduced the subgroup commutativity degree of a finite group, that is, the ratio

\begin{equation}
\begin{aligned}
sd(G) &= \frac{|\{(H, K) \in \mathcal{L}(G) \times \mathcal{L}(G) \mid HK = KH\}|}{|\mathcal{L}(G)|^2},
\end{aligned}
\end{equation}

Key words and phrases. Subgroup commutativity degree, permutable subgroups, centralizers, subgroup lattices.
where \( \mathcal{L}(G) \) denote the subgroup lattice of \( G \). It turns out that

\[
(1.4) \quad \text{sd}(G) = \frac{1}{|\mathcal{L}(G)|^2} \sum_{H \in \mathcal{L}(G)} |\mathcal{C}(H)|,
\]

where

\[
(1.5) \quad \mathcal{C}(H) = \{ K \in \mathcal{L}(G) \mid HK = KH \}.
\]

Variations on this theme have been considered in \([3, 13, 14, 15, 24, 27, 28]\), involving weaker notions of permutability among subgroups. Of course, if \([H, K] = 1\), then \(HK = KH\), where \([H, K] = \langle [h, k] \mid h \in H, k \in K \rangle\). Conversely, \(HK = KH\) does not imply that \([H, K] = 1\). In fact, the equality among the sets \(\{hk \mid h \in H, k \in K\}\) and \(\{kh \mid k \in K, h \in H\}\) does not imply, in general, that all the elements of \(H\) permute with all elements of \(K\). Many examples can be given. Therefore it is meaningful to define the following ratio

\[
(1.6) \quad \text{ssd}(G) = \frac{|\{(H, K) \in \mathcal{L}(G)^2 \mid [H, K] = 1\}|}{|\mathcal{L}(G)|^2},
\]

which we will call strong subgroup commutativity degree of \(G\). It is easy to see that

\[
(1.7) \quad \text{ssd}(G) = \frac{1}{|\mathcal{L}(G)|^2} \sum_{H \in \mathcal{L}(G)} |\text{Comm}_G(H)|,
\]

where

\[
(1.8) \quad \text{Comm}_G(H) = \{ K \in \mathcal{L}(G) \mid [H, K] = 1 \},
\]

and that \(\text{ssd}(G)\) is the probability that the subgroup \([H, K]\) of an arbitrarily chosen pair of subgroups \(H, K\) of a group \(G\) is equal to the trivial subgroup of \(G\). Equivalently, \(\text{ssd}(G)\) expresses the probability that, randomly picked two subgroups of \(G\), the subgroup generated by their commutators is trivial, and, in particular, the two subgroups are permutable. The present paper is devoted to study this notion, showing that it is related to the previous investigations in the area of the measure theory of finite groups.

2. Some basic properties

There are some considerations which come by default with the strong subgroup commutativity degree. A group \(G\) is quasihamiltonian, if all pairs of its subgroups are permutable. \(G\) is called modular, if \(\mathcal{L}(G)\) satisfies the well–known modular law (see \([29]\)). Quasihamiltonian groups were classified by Iwasawa (see \([5, \text{Chapter 6}]\) or \([29, \text{Chapter 2}]\)), who proved that they are nilpotent and modular. This is equivalent to say that a group \(G\) is quasihamiltonian if and only if all its Sylow \(p\)-subgroups are modular (see \([29, \text{Exercise 3 at p.87}]\)), being \(p\) a prime. Therefore the knowledge of quasihamiltonian groups may be reduced to that of modular \(p\)-groups.

In literature, for \(m \geq 3\) the groups

\[
(2.1) \quad M(p^m) = \langle x, y \mid x^{p^m-1} = y^p = 1, y^{-1}xy = x^{p^m-2}+1 \rangle = \langle y \rangle \rtimes \langle x \rangle,
\]

are nonabelian modular \(p\)-groups and their properties have interested the researches of many authors in various contexts (see \([5, 29, 30]\)). An immediate observation is the following. If \(G = M(p^m)\), then \([\langle x \rangle, \langle y \rangle] \neq 1\) and consequently \(\text{sd}(G) = 1\) but \(\text{ssd}(G) \neq 1\). In this sense, it is important to know when the strong subgroup commutativity degree is trivial.
Proposition 2.1. A group $G$ has $ssd(G) = 1$ if and only if it is abelian.

Proof. We have that $ssd(G) = 1$ if, and only if, $[H, K] = 1$ for all subgroups $H$ and $K$ of $G$, if, and only if, $[h, k] = 1$ for all $h \in H$, $k \in K$ and for all $H$ and $K$ in $G$. This implies, in particular, that $[h, k] = 1$ for all $h, k \in G$, that is, $G$ is abelian. Conversely, if $G$ is abelian, then it is clear that $ssd(G) = 1$. □

On another hand, the following relation shows that $ssd(G)$ is related to $d(H, K)$ in a deep way.

Theorem 2.2. Let $H$ and $K$ be two subgroups of a group $G$. Then

$$ssd(G) < \frac{|G|^2}{|\mathcal{L}(G)|^2} \sum_{H, K \in \mathcal{L}(G)} d(H, K).$$

Proof. We claim that

$$(2.2) \quad \bigcup_{K \in \mathcal{L}(G)} C_K(H) = Comm_G(H).$$

Let $T = \bigcup_{K \in \mathcal{L}(G)} C_K(H)$ and $t \in T$. Then there exists a $K_t \in \mathcal{L}(G)$ containing $t$ such that $t \in C_{K_t}(H)$, that is, $[t, H] = 1$, which means that $t$ permutes with all elements of $H$. In particular, the powers of $t$ permutes with all elements of $H$ and so $[(t), H] = 1$, which means $(t)$ is in $Comm_G(H)$. We conclude that $T \subseteq Comm_G(H)$.

Conversely, if $K \in \mathcal{L}(G)$ is in $Comm_G(H)$, then $[K, H] = 1$ and so $K \subseteq C_G(H)$, then $K \subseteq T$. The claim follows.

Therefore

$$(2.3) \quad |\mathcal{L}(G)|^2 ssd(G) = \sum_{H \in \mathcal{L}(G)} |Comm_G(H)| = \sum_{H \in \mathcal{L}(G)} \left| \bigcup_{K \in \mathcal{L}(G)} C_K(H) \right|$$

$$< \sum_{K \in \mathcal{L}(G)} \sum_{H \in \mathcal{L}(G)} |C_K(H)|$$

and we note that the equality cannot occur here as the identity $1 \in C_K(H)$ for all $H$ and $K$ in $\mathcal{L}(G)$. Since $C_K(H) \subseteq C_K(h)$ whenever $h \in H$, we may continue, finding the following upper bound

$$(2.4) \quad \leq \sum_{K \in \mathcal{L}(G)} \sum_{h \in H} \sum_{H, K \in \mathcal{L}(G)} |C_K(h)| = \sum_{H, K \in \mathcal{L}(G)} \left( \sum_{h \in H} |C_K(h)| \right)$$

$$= \sum_{H, K \in \mathcal{L}(G)} d(H, K) |H| |K| \leq |G|^2 \sum_{H, K \in \mathcal{L}(G)} d(H, K).$$

Remark 2.3. We want just to illustrate two points of views which allow us to decide whether a group $G$ is abelian or not. The first deals with the subgroups: from Proposition 2.1, $G$ is abelian if and only if $ssd(G)$ is trivial. The second deals with the elements: $G$ is abelian if and only if $d(G)$ is trivial. Theorem 2.2 is relevant, because it correlates $d(G)$ with $ssd(G)$. This is very helpful, because we have literature on $d(G)$ but few is known about $ssd(G)$ and $sd(G)$. 
In virtue of the previous remark, the following result is significative and answers partially some open questions in [31]. We will see, concretely, that the argument of Theorem 2.2 is very general and can be adapted to the context of \( sd(G) \).

**Theorem 2.4.** Let \( H \) and \( K \) be two subgroups of a group \( G \). Then

\[
sd(G) \geq \frac{1}{|L(G)|^2} \sum_{H \in L(G)} \left| \bigcap_{h \in H} C_K(h) \right|
\]

with

\[
\sum_{H,K \in L(G)} d(H,K) |H| |K| \geq \sum_{H,K \in L(G)} \left| \bigcap_{h \in H} C_K(h) \right|.
\]

**Proof.** From Theorem 2.2 (more precisely from (3.18)), we may restrict to prove only the first inequality. In order to do this, we claim that

\[
(2.5) \quad C_K(H) \subseteq \bigcup_{K \in L(G)} C_K(H) \subseteq C(H).
\]

The first inclusion is trivial. Let \( S = \bigcup_{K \in L(G)} C_K(H) \) and \( s \in S \). Then there exists a \( K_s \in L(G) \) containing \( s \) such that \( s \in C_{K_s}(H) \), that is, \([s,H] = 1\), which means that \( s \) permutes with all elements of \( H \). In particular, \([s,H] = 1\) then \( \langle s \rangle H = H \langle s \rangle \), which means \( \langle s \rangle \in C(H) \). We conclude that \( S \subseteq C(H) \).

Therefore

\[
(2.6) \quad |L(G)|^2 \cdot sd(G) = \sum_{H \in L(G)} |C(H)| \geq \sum_{H \in L(G)} \left| \bigcup_{K \in L(G)} C_K(H) \right| \geq \sum_{H \in L(G)} |C_K(H)|
\]

but we observe that in general the following is true

\[
(2.7) \quad \bigcap_{h \in H} C_K(h) = C_K(H)
\]

so that

\[
(2.8) \quad = \sum_{H \in L(G)} \left| \bigcap_{h \in H} C_K(h) \right|.
\]

On another hand, we note that

\[
(2.9) \quad \sum_{H,K \in L(G)} d(H,K) |H| |K| = \sum_{H,K \in L(G)} \left( \sum_{h \in H} |C_K(h)| \right).
\]

\[
= \sum_{K \in L(G)} \left( \sum_{h \in H} |C_K(h)| \right) \geq \sum_{K \in L(G)} \left( \sum_{H \in L(G)} \left| \bigcap_{h \in H} C_K(h) \right| \right).
\]

\[ \square \]

In the rest of this section we reformulate \( ssd(G) \) in terms of arithmetic functions.

It is possible to rewrite \( ssd(G) \) in the following form:

\[
(2.10) \quad ssd(G) = \frac{1}{|L(G)|^2} \sum_{X,Y \in L(G)} \varphi(X,Y),
\]
where \( \varphi : \mathcal{L}(G)^2 \to \{0, 1\} \) is the function defined by

\[
\varphi(X, Y) = \begin{cases} 
1, & \text{if } [X, Y] = 1, \\
0, & \text{if } [X, Y] \neq 1.
\end{cases}
\]

The reader may note that \( \varphi(X, Y) = \varphi(Y, X) \), that is, \( \varphi \) is symmetric in the variables \( X \) and \( Y \). There is a corresponding property of symmetry for the subgroup commutativity degree in [30, Section 2], but, in general, this property depends on the permutability which we are going to study. For instance, this does not happen for weaker forms of permutability with respect to the maximal subgroups, as shown in [24]. However, the introduction of the function \( \varphi \) allows us to simplify the notations. In fact, if \( Z \) is a given subgroup of \( G \) and we consider the sets

\[
\mathcal{B}_1 = \{ X \in \mathcal{L}(G) : Z \subseteq X \} \quad \text{and} \quad \mathcal{B}_2 = \{ X \in \mathcal{L}(G) : X \subset Z \},
\]

then \( \mathcal{B}_1 \cup \mathcal{B}_2 \subseteq \mathcal{L}(G) \) and so

\[
|\mathcal{L}(G)|^2 \quad \text{ssd}(G) \geq \sum_{X, Y \in \mathcal{B}_1 \cup \mathcal{B}_2} \varphi(X, Y),
\]

(2.12)

\[
= \sum_{X, Y \in \mathcal{B}_1} \varphi(X, Y) + \sum_{X, Y \in \mathcal{B}_2} \varphi(X, Y) + 2 \sum_{X \in \mathcal{B}_1} \sum_{Y \in \mathcal{B}_2} \varphi(X, Y).
\]

A consequence of this equation is examined below and overlaps a similar situation for \( \text{sd}(G) \) in [30].

**Proposition 2.5.** Let \( G \) be a group and \( N \) be a normal subgroup of \( G \). Then

\[
\text{ssd}(G) \geq \frac{1}{|\mathcal{L}(G)|^2} \left( \left( |\mathcal{L}(N)| + |\mathcal{L}(G/N)| - 1 \right) \right)^2
\]

\[
+ (\text{ssd}(N) - 1)|\mathcal{L}(N)|^2 + (\text{ssd}(G/N) - 1)|\mathcal{L}(G/N)|^2 \right).
\]

**Proof.** We are going to rewrite more properly the terms in the left side of (2.12).

\[
|\mathcal{L}(G/N)|^2 \quad \text{ssd}(G/N) = \sum_{X, Y \in \mathcal{B}_1} \varphi(X, Y); \quad \text{(2.13)}
\]

\[
|\mathcal{L}(N)|^2 \quad \text{ssd}(G/N) - 2|\mathcal{L}(N)| + 1 = \sum_{X, Y \in \mathcal{B}_2 \cup \{N\}} \varphi(X, Y)
\]

\[
- 2 \sum_{X \in \mathcal{B}_2 \cup \{N\}} \varphi(X, N) + 1 = \sum_{X, Y \in \mathcal{B}_2} \varphi(X, Y); \quad \text{(2.14)}
\]

\[
2|\mathcal{L}(G/N)|(|\mathcal{L}(N)| - 1) = 2|\mathcal{B}_1||\mathcal{B}_2| = 2 \sum_{X \in \mathcal{B}_1} \sum_{Y \in \mathcal{B}_2} \varphi(X, Y). \quad \text{(2.15)}
\]

Replacing these expressions in (2.12), the result follows. \( \square \)

We list three consequences of Proposition 2.5, overlapping similar situations for \( \text{sd}(G) \) in [30]. Their proof is omitted, since it is enough to note that for a normal abelian subgroup \( N \) of \( G \) we have \( \text{ssd}(G/N) = 1 \) by Proposition 2.5 and, if it is of prime index in \( G \), then \( |\mathcal{L}(G/N)| = 2 \).

**Corollary 2.6.** Let \( G \) be a group and \( N \) be a normal subgroup of \( G \) such that \( G/N \) and \( N \) are abelian. Then

\[
\text{ssd}(G) \geq \frac{1}{|\mathcal{L}(G)|} \left( |\mathcal{L}(N)| + |\mathcal{L}(G/N)| - 1 \right)^2.
\]
Corollary 2.7. Let $G$ be a group and $N$ be a normal subgroup of $G$ of prime index. Then
\[
\text{ssd}(G) \geq \frac{1}{|\mathcal{L}(G)|^2} \left( \text{ssd}(N)|\mathcal{L}(N)|^2 + 2|\mathcal{L}(N)| + 1 \right).
\]

Corollary 2.8. A nonabelian solvable group $G$ has
\[
\text{ssd}(G) \geq \frac{1}{|\mathcal{L}(G)|^2} \left( \text{ssd}(G')|\mathcal{L}(G')|^2 + 2|\mathcal{L}(G')| + 1 \right).
\]

In particular, if $G$ is metabelian, then
\[
\text{ssd}(G) \geq \frac{1}{|\mathcal{L}(G)|^2} \left( |\mathcal{L}(G')|^2 + 2|\mathcal{L}(G')| + 1 \right).
\]

Now we list some general bounds, related to subgroups and quotients. In a different context, these relations have been found in [24].

Theorem 2.9. Let $H$ be a subgroup of a group $G$. Then
\[
\frac{|\mathcal{L}(H)|^2}{|\mathcal{L}(G)|^2} \text{ssd}(H) \leq \text{ssd}(G)
\]
and for all subgroups $L$ and $M$ of $H$
\[
\frac{1}{|\mathcal{L}(G)|^2} \sum_{L \in \mathcal{L}(H)} \left| \bigcap_{l \in L} C_M(l) \right| \leq \text{sd}(H) \leq \text{sd}(G).
\]

Proof. We proceed to prove the first inequality. The result is obviously true for $H = G$ and then we may assume $H \neq G$. Since $\mathcal{L}(H) \subseteq \mathcal{L}(G)$,
\[
|\mathcal{L}(H)|^2 \text{ssd}(H) = \sum_{X,Y \in \mathcal{L}(H)} \varphi(X,Y) \leq \sum_{X,Y \in \mathcal{L}(G)} \varphi(X,Y) = |\mathcal{L}(G)|^2 \text{ssd}(G).
\]

The inequality follows.

Now we proceed to prove the remaining part. When we consider the corresponding function $\psi$, related to $\text{sd}(G)$ (details can be found in [30,31]), instead of $\varphi$, we may overlap the previous argument and find that $\frac{|\mathcal{L}(H)|^2}{|\mathcal{L}(G)|^2} \text{ssd}(H) \leq \text{sd}(G)$. From Theorem 2.3 it follows that
\[
\frac{1}{|\mathcal{L}(H)|^2} \sum_{L \in \mathcal{L}(H)} \left| \bigcap_{l \in L} C_M(l) \right| \leq \text{sd}(H)
\]
then
\[
\frac{|\mathcal{L}(H)|^2}{|\mathcal{L}(G)|^2} \left( \frac{1}{|\mathcal{L}(H)|^2} \sum_{L \in \mathcal{L}(H)} \left| \bigcap_{l \in L} C_M(l) \right| \right) \leq \text{sd}(H)
\]
and the result follows.

In [29] Chapter 1, it is shown that $\mathcal{L}(G_1 \times G_2) \neq \mathcal{L}(G_1) \times \mathcal{L}(G_2)$ in general, but if $G_1$ and $G_2$ have coprime orders then it is true. This motivates our assumption in the following proposition.

Proposition 2.10. For two groups $G_1$ and $G_2$ of coprime orders,
\[
\text{ssd}(G_1 \times G_2) = \text{ssd}(G_1) \cdot \text{ssd}(G_2).
\]
Proof. We have \( \mathcal{L}(G_1 \times G_2) = \mathcal{L}(G_1) \times \mathcal{L}(G_2) \), because \( G_1 \) and \( G_2 \) have coprime orders. Therefore, with obvious meaning of symbols,

\[
(2.19) \quad \text{ssd}(G_1 \times G_2) = \frac{1}{|\mathcal{L}(G_1) \times \mathcal{L}(G_2)|^2} \sum_{A_1 \times A_2 \in \mathcal{L}(G_1) \times \mathcal{L}(G_2)} |\text{Comm}_{G_1 \times G_2}(A_1 \times A_2)|
\]

\[
= \frac{1}{|\mathcal{L}(G_1) \times \mathcal{L}(G_2)|^2} \sum_{A_1 \times A_2 \in \mathcal{L}(G_1) \times \mathcal{L}(G_2)} |\text{Comm}_{G_1}(A_1) \times \text{Comm}_{G_2}(A_2)|
\]

\[
= \left( \frac{1}{|\mathcal{L}(G_1)|^2} \sum_{A_1 \in \mathcal{L}(G_1)} |\text{Comm}_{G_1}(A_1)| \right) \left( \frac{1}{|\mathcal{L}(G_2)|^2} \sum_{A_2 \in \mathcal{L}(G_2)} |\text{Comm}_{G_2}(A_2)| \right)
= \text{ssd}(G_1) \cdot \text{ssd}(G_2).
\]

Hence the proposition follows. \( \square \)

**Corollary 2.11.** Proposition (2.10) is still true for finitely many factors.

**Proof.** We can mimick the proof of Proposition (2.10) \( \square \)

### 3. Multiple strong subgroup commutativity degree

In analogy with \( d^{(n)}(H,G) \) \((n \geq 1)\), introduced in [12], the notion of strong subgroup commutativity degree, given in Section 1, can be further generalized in the following way:

\[
(3.1) \quad ssd^{(n)}(H,G) = \frac{|\{(L_1, \ldots, L_n, K) \in \mathcal{L}(H)^n \times \mathcal{L}(G) \mid |L_1, \ldots, L_n, K| = 1\}|}{|\mathcal{L}(H)|^n \cdot |\mathcal{L}(G)|}
\]

In particular, if \( n = 1 \) and \( H = G \), then \( ssd^{(1)}(G,G) = ssd(G) \). Briefly, \( ssd^{(n)}(H) \) denotes

\[
(3.2) \quad ssd^{(n)}(H, H) = \frac{|\{(L_1, \ldots, L_n, L_{n+1}) \in \mathcal{L}(H)^{n+1} \mid |L_1, \ldots, L_n, L_{n+1}| = 1\}|}{|\mathcal{L}(H)|^{n+1}}
\]

On another hand, we note that

\[
(3.3) \quad [L_1, \ldots, L_n, K] = [[L_1, \ldots, L_n], K] = \ldots = [[[L_1, L_2], L_3] \ldots L_n], K] = 1
\]

and so

\[
(3.4) \quad \text{Comm}_G(L_1, \ldots, L_n) = \{K \in \mathcal{L}(G) \mid |L_1, \ldots, L_n, K| = 1\},
\]

\[
(3.5) \quad \text{Comm}_{H \times G}(L_1, \ldots, L_{n-1}) = \{(L_n, K) \in \mathcal{L}(H) \times \mathcal{L}(G) \mid |[[L_1, \ldots, L_n-1], L_n], K| = 1\}
\]

\[
\text{Comm}_{H^{-1} \times G}(L_1) = \{(L_2, L_3, \ldots, L_n, K) \in \mathcal{L}(H)^{n-1} \times \mathcal{L}(G) \mid |[[L_1, L_2], \ldots, L_n], K| = 1\}
\]

\[
\text{Comm}_{H^{-2} \times G}(L_1, L_2) \subseteq \text{Comm}_{H^{n-2} \times G}(L_1, L_2) \subseteq \ldots \subseteq \text{Comm}_{H \times G}(L_1, \ldots, L_{n-1}) \subseteq \text{Comm}_{G}(L_1, \ldots, L_n).
\]

From the above inclusions we observe that for \( n \) which is growing the \( \text{Comm}_{H^{-1} \times G}(L_1) \) is getting to the trivial subgroup. Therefore

\[
(3.6) \quad |\mathcal{L}(H)|^n \cdot |\mathcal{L}(G)| \cdot ssd^{(n)}(H, G) = \sum_{L_1, \ldots, L_n \in \mathcal{L}(H)} |\text{Comm}_G(L_1, \ldots, L_n)|
\]
...≥sequence. Therefore, if we fix \( ssd \), the second inequality follows once we note that
\[
\lim_{n \to \infty} \frac{1}{|\mathcal{L}(H)|} \cdot \lim_{n \to \infty} \sum_{L_1, \ldots, L_n \in \mathcal{L}(H)} |\text{Comm}_{H^{-1} \times G}(L_1)| = 1.
\]
This is a qualitative argument which shows that it is meaningful to consider values of probabilities of \( ssd^{(n)}(H, G) \) for a small number of commuting subgroups. At the same time, the above construction shows that \( ssd^{(n)}(H, G) \) is a strictly decreasing sequence of numbers in \([0, 1]\) in the variable \( n \). Namely,
\[
(3.8) \quad ssd^{(1)}(H, G) \geq ssd^{(2)}(H, G) \geq \ldots \geq ssd^{(n)}(H, G) \geq ssd^{(n+1)}(H, G) \geq \ldots
\]
We want to point out that a similar treatment can be done for \( sd(G) \), as proposed in a series of open problems in [31], where the corresponding version of \( ssd^{(n)}(H, G) \) is called relative subgroup commutativity degree.
As done in Section 2, we may rewrite \( ssd^{(n)}(H, G) \) in the following form:
\[
(3.9) \quad ssd^{(n)}(H, G) = \frac{1}{|\mathcal{L}(H)|^{n-1} |\mathcal{L}(G)|} \sum_{X_1, \ldots, X_n \in \mathcal{L}(H)} \varphi_n(X_1, \ldots, X_n, Y),
\]
where \( \varphi_n : \mathcal{L}(H)^n \times \mathcal{L}(G) \to \{0, 1\} \) is the function defined by
\[
(3.10) \quad \varphi_n(X_1, \ldots, X_n,Y) = \begin{cases} 1, & \text{if } [X_1, \ldots, X_n, Y] = 1, \\ 0, & \text{if } [X_1, \ldots, X_n, Y] \neq 1 \end{cases}
\]
and continues to be symmetric.

**Proposition 3.1.** Given subgroup \( H \) of a group \( G \),
\[
ssd^{(n)}(H, G) \leq ssd^{(n)}(G, G) \leq ssd(G) \leq sd(G).
\]

**Proof.** We begin to prove the first inequality. Since \( \mathcal{L}(H) \subseteq \mathcal{L}(G) \),

\[
(3.11) \quad ssd^{(n)}(H, G) \leq |\mathcal{L}(H)|^{n-1} |\mathcal{L}(G)| \cdot ssd^{(n)}(H, G) = \sum_{X_1, \ldots, X_n \in \mathcal{L}(H)} \varphi_n(X_1, \ldots, X_n, Y)
\]

\[
(3.12) \quad \leq \sum_{X_1, \ldots, X_n, Y \in \mathcal{L}(G)} \varphi_n(X_1, \ldots, X_n, Y) = |\mathcal{L}(G)|^{n-1} |\mathcal{L}(G)| \cdot ssd^{(n)}(G, G)
\]

The second inequality follows once we note that \( ssd^{(n)}(H, G) \) is a decreasing sequence. Therefore, if we fix \( H = G \), then \( ssd(G) = ssd^{(1)}(G, G) \geq ssd^{(2)}(G, G) \geq \ldots \geq ssd^{(n)}(G, G) \geq \ldots \). The last inequality follows once we note that \( \text{Comm}_C(H) \subseteq \mathcal{L}(H) \) and that
\[
(3.13) \quad sd(G) = \frac{1}{|\mathcal{L}(G)|^2} \sum_{H \in \mathcal{L}(G)} |\text{Comm}_C(H)| \leq \frac{1}{|\mathcal{L}(G)|^2} \sum_{H \in \mathcal{L}(G)} |\mathcal{L}(H)| = sd(G).
\]
Proposition 3.2. For two groups $C$ and $D$ of coprime orders and two subgroups $A \leq C$ and $B \leq D$, \[ ssd^{(n)}(A \times B, C \times D) = ssd^{(n)}(A, C) \cdot ssd^{(n)}(B, D). \]

Proof.
\begin{align*}
\text{(3.14)} & \quad ssd^{(n)}(A \times B, C \times D) \\
& = \frac{1}{|\mathcal{L}(A \times B)|^{n} \cdot |\mathcal{L}(C \times D)|} \sum_{A_{1} \times B_{1}, \ldots, A_{n} \times B_{n} \in \mathcal{L}(A \times B)} |\text{Comm}_{A \times B}(A_{1} \times B_{1}, \ldots, A_{n} \times B_{n})| \\
& = \frac{1}{|\mathcal{L}(A)|^{n} \cdot |\mathcal{L}(B)|^{n} \cdot |\mathcal{L}(C)| \cdot |\mathcal{L}(D)|} \\
& \quad \cdot |\text{Comm}_{B}(B_{1}, \ldots, B_{n})| \bigg( \sum_{A_{1} \times B_{1}, \ldots, A_{n} \times B_{n} \in \mathcal{L}(A \times B)} |\text{Comm}_{A}(A_{1}, \ldots, A_{n})| \bigg) \\
& = \frac{1}{|\mathcal{L}(A)|^{n} \cdot |\mathcal{L}(C)|} \bigg( \sum_{A_{1}, \ldots, A_{n} \in \mathcal{L}(A)} |\text{Comm}_{A}(A_{1}, \ldots, A_{n})| \bigg) \\
& \quad \cdot \frac{1}{|\mathcal{L}(B)|^{n} \cdot |\mathcal{L}(D)|} \bigg( \sum_{B_{1}, \ldots, B_{n} \in \mathcal{L}(B)} |\text{Comm}_{B}(B_{1}, \ldots, B_{n})| \bigg) \\
& = ssd^{(n)}(A, C) \cdot ssd^{(n)}(B, D).
\end{align*}

We note that Proposition 3.2 follows from Proposition 3.2 when $n = 1$, $A = C = G_{1}$, $B = D = G_{2}$.

Corollary 3.3. Proposition 3.2 is still true for finitely many factors.

Proof. We can mimick the proof of Proposition 3.2.

We end with a variation on the theme of Theorems 2.2 and 2.4.

Theorem 3.4. Let $H$ and $K$ be two subgroups of a group $G$. Then for all $n \geq 1$
\[ ssd^{(n)}(H, H) < \frac{|H|^{n+1}}{|\mathcal{L}(H)|^{n+1}} \sum_{K \in \mathcal{L}(H)} d^{(n)}(H, K). \]

Proof. Overlapping the argument in the proof of Theorem 2.2, we firstly prove that
\begin{equation}
\bigcup_{(L_{2}, \ldots, L_{n}, L_{n+1}) \in \mathcal{L}(H)^{n}} C_{H^{n}}(L_{1}) = \text{Comm}_{H^{n}}(L_{1}),
\end{equation}
where
\begin{equation}
\text{Comm}_{H^{n}}(L_{1}) = \text{Comm}_{H^{n-1} \times H}(L_{1})
\end{equation}
\[ = \{(L_{2}, L_{3}, \ldots, L_{n}, L_{n+1}) \in \mathcal{L}(H)^{n-1} \times \mathcal{L}(H) \mid \ldots [L_{1}, L_{2}, \ldots, L_{n}, L_{n+1}] = 1\} \]
and then
\begin{equation}
|\mathcal{L}(H)|^{n+1} ssd^{(n)}(H, H) = \sum_{L_{1} \in \mathcal{L}(H)} |\text{Comm}_{H^{n}}(L_{1})|
\end{equation}
\[
\begin{align*}
&= \sum_{L_1 \in \mathcal{L}(H)} \left| \bigcup_{(L_2, \ldots, L_{n+1}) \in \mathcal{L}(H)^n} C_{H^n}(L_1) \right| \\
&< \sum_{(L_2, \ldots, L_n, L_{n+1}) \in \mathcal{L}(H)^n} \sum_{L_1 \in \mathcal{L}(H)^n} |C_{H^n}(L_1)|
\end{align*}
\]

and we note that the equality must be strict for the same motivation of the corresponding step in the proof of Theorem 2.2. Since \(C_{H^n}(L_1) \subseteq C_{H^n}(l_1)\) whenever \(l_1 \in L_1\), we may continue, finding that

\[
(3.18) \leq \sum_{(L_2, \ldots, L_n, L_{n+1}) \in \mathcal{L}(H)^n} \sum_{L_1 \in \mathcal{L}(H)} |C_{H^n}(l_1)|
\]

\[
= \sum_{K \in \mathcal{L}(H)} d^{(n)}(K, K) |K|^{n+1} \leq |H|^{n+1} \sum_{K \in \mathcal{L}(H)} d^{(n)}(K, K).
\]

□

Roughly speaking, in the proof of Theorem 2.2 we may replace the role of \(\varphi = \varphi_2\) with that of \(\varphi_n\) for \(n > 2\). We will find the following generalization of Theorem 2.9, whose proof is easy to check and so it is omitted.

**Theorem 3.5.** Let \(H\) be a subgroup of a group \(G\). Then for all \(n \geq 1\)

\[
\frac{|\mathcal{L}(H)|^{n+1}}{|\mathcal{L}(G)|^{n+1}} \text{ssd}^{(n)}(H) \leq \text{ssd}^{(n)}(G).
\]

We note that a similar treatment can be done for the relative subgroup commutativity degree in [31], since the arguments involve only combinatorial properties and set theory. This fact motivates to conjecture that the context of infinite compact groups, once a suitable Haar measure is replaced with \(\text{ssd}(G)\) or with \(\text{sd}(G)\), may be subject to an analogous treatment.

### 4. Two Applications

Here we illustrate an application to the theory of characters and another to the dihedral groups. Relations with the theory of characters are due to the fact that in a group \(G\)

\[
(4.1) \quad d(G) = \frac{|\text{Irr}(G)|}{|G|},
\]

where \(\text{Irr}(G)\) denotes the set of all irreducible complex characters of \(G\). For an element \(g\) of \(G\), let

\[
(4.2) \quad \xi(g) = |(X, Y) \in \mathcal{L}(\langle g \rangle) \times \mathcal{L}(G) \mid |X, Y| = 1|).
\]

Thus,

\[
(4.3) \quad \text{ssd}(\langle g \rangle, G) = \frac{\xi(g)}{|\mathcal{L}(\langle g \rangle)| |\mathcal{L}(G)|}.
\]

**Lemma 4.1.** \(\xi(g)\) is a class function.
Proof. It is enough to note that, for each \( a \in G \), the map
\[
(4.4) \quad f : (X, Y) \mapsto f(X, Y) = (aX a^{-1}, aYa^{-1})
\]
defines a one to one correspondence between the sets \( \{(X, Y) \in \mathcal{L}(\langle g \rangle) \times \mathcal{L}(G) \mid [X, Y] = 1\} \) and \( \{(X, Y) \in \mathcal{L}(\langle aga^{-1} \rangle) \times \mathcal{L}(G) \mid [X, Y] = 1\} \). □

Thus, it is meaningful to write
\[
(4.5) \quad \xi(g) = \sum_{\chi \in \text{Irr}(G)} \langle [\xi], \chi \rangle \chi(g)
\]
where \( \langle [\cdot], \cdot \rangle \) denotes the usual inner product of characters, defined by
\[
(4.6) \quad \langle [\xi], \chi \rangle = \frac{1}{|G|} \sum_{g \in G} \xi(g) \overline{\chi(g)} = \frac{1}{|G|} \sum_{g \in G} \xi(g) \chi(g^{-1}).
\]

We recall that a class function defined on a finite group \( G \) is said to be an \( R \)-
generalized character of \( G \), for any ring \( \mathbb{Z} \subseteq R \subseteq \mathbb{C} \), if it is an \( R \)-linear combination of irreducible complex characters of \( G \).

**Theorem 4.2.** \( \xi \) is a \( \mathbb{Q} \)-generalized character of \( G \).

**Proof.** Clearly, if two elements \( x \) and \( y \) of \( G \) generate the same cyclic group then \( \xi(x) = \xi(y) \). Suppose that \( o(x) = o(y) = n \). Let \( \varepsilon \) be a primitive \( n \)th root of unity. We have \( y = x^m \) for some \( m \) with \( (m, n) = 1 \) and thus \( \varepsilon^m \) is a primitive \( n \)th root of unity. As usual, \( \text{Gal}(\mathbb{Q}[\varepsilon]/\mathbb{Q}) \) denotes the Galois group, related to the algebraic extension \( \mathbb{Q}[\varepsilon] \) over \( \mathbb{Q} \), obtained adding \( \varepsilon \). Therefore, for any \( \sigma \in \text{Gal}(\mathbb{Q}[\varepsilon]/\mathbb{Q}) \) we have
\[
(4.7) \quad \chi(x)^\sigma = \sum \varepsilon_i^\sigma = \sum \varepsilon_i^m = \chi(x^m).
\]
Thus for any \( \chi \in \text{Irr}(G) \) and \( g \in G \),
\[
(4.8) \quad \chi(g)^\sigma = \chi(g^m)
\]
and hence \( (\delta(g) \chi(g^{-1}))^\sigma = \delta(g^m) \chi(g^{-m}) \). Hence \( \sigma \) fixes \( \sum_{g \in G} \delta(g) \chi(g^{-1}) \) and this completes the proof. □

**Corollary 4.3.** \( |G| [\xi, \chi] \) is an integer for all \( \chi \in \text{Irr}(G) \).

**Proof.** Since \( \chi(g) \) is an algebraic integer the result follows from Lemma \[41\] and Theorem \[42\]. □

For the second application, the dihedral group
\[
(4.9) \quad D_{2n} = \langle x, y \mid x^2 = y^n = 1, x^{-1}yx = y^{-1} \rangle
\]
of symmetries of a regular polygon with \( n \geq 1 \) edges has order \( 2n \) and a well–known
description of \( |\mathcal{L}(D_{2n})| \) can be found in [29, 31, 31]. For instance, it is easy to see that \( D_{2n} \cong C_2 \rtimes C_n \) is the semidirect product of a cyclic group \( C_2 \) of order 2 acting by inversion on a cyclic group \( C_n \) of order \( n \). For every divisor \( r \) of \( n \), \( D_{2n} \) has a subgroup isomorphic to \( C_r \), namely \( \langle x^r \rangle \), and \( \frac{n}{r} \) subgroups isomorphic to \( D_{2r} \), namely \( \langle x^{2i}, x^{i-1}, y \rangle \) for \( i = 1, 2, \ldots, \frac{n}{r} \). Then
\[
(4.10) \quad |\mathcal{L}(D_{2n})| = \sigma(n) + \tau(n),
\]
where \( \sigma(n) \) and \( \tau(n) \) are the sum and the number of all divisors of \( n \), respectively.
The next result generalizes the above considerations, when we have a group with a structure very close to that of \( D_{2n} \).
Corollary 4.4. Assume that $G$ is a metabelian group of even order. If $|\mathcal{L}(G)| = \sigma\left(\frac{|G|}{2}\right) + \tau\left(\frac{|G|}{2}\right)$ and $G'$ is cyclic, then

$$\frac{\left(\tau(G') + 1\right)^2}{\left(\sigma\left(\frac{|G|}{2}\right) + \tau\left(\frac{|G|}{2}\right)\right)^2} \leq \sum_{H,K \in \mathcal{L}(G)} \varphi(H,K) \leq \frac{|G|^2}{\left(\sigma\left(\frac{|G|}{2}\right) + \tau\left(\frac{|G|}{2}\right)\right)^2} \sum_{H,K \in \mathcal{L}(G)} d(H,K).$$

Proof. Since $G'$ is cyclic, $|\mathcal{L}(G')| = \tau(G')$. Then the lower bound follows from Corollary 2.8 specifying the numerical values of the subgroup lattices. From Theorem 2.2 we get the upper bound, adapted to our case. The result follows. \qed

Corollary 4.4 is a counting formula for the number of permuting subgroups via $\varphi$, or, equivalently, via the strong subgroup commutativity degree and the commutativity degree. This observation is important in virtue of the fact that we know explicitly $d(H,K)$ by results in \cite{2,7,8,9,12,18,19}.
