Let $G$ be the group of $k$-points of a connected reductive $k$-group and $H$ a symmetric subgroup associated to an involution $\sigma$ of $G$. We prove a polar decomposition $G = KAH$ for the symmetric space $G/H$ over any local field $k$ of characteristic not 2. Here $K$ is a compact subset of $G$ and $A$ is a finite union of groups $A_i$. These groups $A_i$ are the $k$-points of maximal $(k, \sigma)$-split tori, one for each $H$-conjugacy class.

This decomposition is analogous to the well-known polar decomposition $G = KAH$ for a real symmetric space $G/H$.

1 Introduction

We begin with a short motivation of this article. It is well-known that every nondegenerate quadratic form on $\mathbb{R}^n$ can be put into diagonal form by an orthogonal base change.

This statement is an instance of the so-called polar decomposition $G = KAH$ for a real symmetric space $G/H$ (see Section 5.1), with $G = \text{GL}(n, \mathbb{R})$, with $H = \text{O}(p, n-p)$, with $K = \text{O}(n)$ and with $A$ the subgroup of diagonal matrices of $G$.

Let $k$ be a non-Archimedean local field. It is also well known that if the residual characteristic of $k$ is not 2, every nondegenerate quadratic form on $k^n$ can be put into...
diagonal form by a base change preserving the sup norm (see Section 5.2). The aim of this article is to prove a polar decomposition for any symmetric space $G/H$ over a local field of characteristic not 2.

Here is the precise statement of our polar decomposition. Let $k$ be a non-Archimedean local field of characteristic not 2. Let $G$ be a connected reductive $k$-group, $\sigma$ a $k$-involution of $G$ and $H$ an open $k$-subgroup of the group $G^\sigma$ of $\sigma$-fixed points. A $k$-torus $S$ of $G$ is said to be $(k, \sigma)$-split if it is $k$-split and $\sigma(g) = g^{-1}$ for all $g \in S$.

We use the notation $G, H, S, \ldots$ to denote the groups of $k$-points of $G, H, S, \ldots$. By a theorem of Helminck and Wang [9], there are only finitely many $H$-conjugacy classes of maximal $(k, \sigma)$-split tori of $G$. Choose a set $\{A_i : 1 \leq i \leq n\}$ of representatives of $H$-conjugacy class of maximal $(k, \sigma)$-split tori of $G$ and set $A = \cup_{i=1}^n A_i$.

**Theorem 1.1.** There exists a compact subset $K$ of $G$ such that we have

$$G = KAH.$$ 

We remark that all the subgroups $A_i, 1 \leq i \leq n$ are needed, up to $H$-conjugacy, in the above decomposition (Lemma 5.8) and that we cannot in general choose $K$ to be a compact subgroup of $G$.

The proof relies simultaneously on algebraic properties of the symmetric spaces $G/H$ mostly due to Helminck and Wang, as well as on geometric properties of the Bruhat–Tits building $X_G$ of $G$. In fact, we will deduce Theorem 1.1 from the following geometric statement: (see (4.3) for the definition of $\sigma$-apartment):

**Theorem 1.2.** There exists a constant $C > 0$ such that any point $x \in X_G$ has distance at most $C$ from some $\sigma$-apartment in $X_G$. 

This article is organized as follows: in Section 2 we recall the construction of the Bruhat–Tits building of $G$, as well as the polar decomposition for the group $G$ itself which is a consequence of the Bruhat–Tits theory. After recalling in Section 3 a few known facts on symmetric spaces over local fields, we prove in Section 4 a geometric version of the polar decomposition (Theorem 4.7) from which we deduce Theorem 1.1. We finish in Section 5, by giving a few examples and comments. It may be a good idea for a reader to start with this section which is independent of the rest of the article.

We apply our polar decomposition given in Theorem 1.1 to some counting and equidistribution results, with rate of convergence, for $S$-integral points on symmetric spaces in a forthcoming article [3]. That is why we do not work here in the more general setting of a valued field. This article has been announced in [2].
After a lecture by the first author in CIRM on this article, P. Delorme gave him the preprint [6] with V. Sécherre, written simultaneously and independently, in which they prove similar results when the residual characteristic is not 2. Their method uses the Bruhat–Tits buildings in a more algebraic way.

2 Bruhat–Tits Buildings and Polar Decomposition

Let \( k \) be a non-Archimedean local field with a valuation \( \omega \) and \( G \) be the group of \( k \)-points of a reductive \( k \)-group \( G \). In this section we recall the definition of the Bruhat–Tits building \( X_G \) of \( G \), which is a metric space on which \( G \) acts properly by isometries with a compact fundamental domain. This metric space is very similar to the Riemannian symmetric space associated to a real reductive group. It is a very important tool since it gives a geometric insight in understanding the algebraic properties of \( G \). It is precisely this insight that we will use to prove our main theorem in this article. We also recall several properties of \( X_G \) that we will need later.

The construction of \( X_G \) relies on a cautious construction of certain open compact subgroups of \( G \). All the theory on building presented below is due to Bruhat and Tits in [4] and [5] but the readers may find references such as [20], [12], [17] [14, 3.4] or [11] shorter and more helpful.

2.1 Euclidean buildings

We first give the axiomatic definition of a building. All our buildings will be Euclidean and polysimplicial.

Let \( E \) be a real affine space endowed with an Euclidean distance \( d_E \) and let \( W \) be a discrete subgroup, generated by (hyperplane) reflections, of the group of affine isometries of \( E \). Let \( V \) be the corresponding vector space and \( ^W V \subset V \) the finite group given by the linear part of \( W \). Here are a few vocabularies. A wall is a hyperplane of \( E \) pointwise fixed by a reflection of \( W \). A root is a closed halfspace of \( E \) bounded by a wall. A facet is an equivalence class in \( E \) with respect to the relation: \( x \sim y \) if and only if \( x \) and \( y \) live in the same roots. The type of a facet is its \( W \)-orbit. A chamber is a facet which is open in \( E \). A point \( x \) in \( E \) is special if every wall is parallel to a wall containing \( x \). Such a point always exists.

Buildings are always associated to such a pair \((E, W)\). Roughly, they are obtained by gluing together copies of \( E \) along convex union of facets in such a way that they satisfy very strong geometric properties. More precisely:
A building, modeled on \((E, W)\), is a metric space \((X, d)\) endowed with a system of apartments, i.e. a collection of subsets \(A\) of \(X\) called apartments, and a partition of \(X\) into subsets called facets such that:

- for each apartment \(A\) there is an isometry from \(E\) to \(A\) sending facets to facets,
- any two points of \(X\) is contained in at least one apartment,
- for any apartments \(A\) and \(A'\), the intersection \(A \cap A'\) is a closed convex subset of \(A\) which is a union of facets and there is a facet preserving isometry from \(A\) to \(A'\) which is the identity on \(A \cap A'\).

As a metric space, every building \(X\) is \(\text{CAT}(0)\)-space [10]. A translation of \(X\) is an isometry of \(X\) which induces a translation in each apartment \(A \simeq E\) of \(X\). The building \(X\) is essential if the only translation of \(X\) is the identity. Denote by \(V_0\) the vector space of translations of \(X\). The quotient \(X_{\text{ess}} = V_0 \backslash X\) is naturally an essential building which is called the essential quotient of \(X\) and \(X\) is isometric to the Euclidean product \(X_{\text{ess}} \times V_0\).

### 2.2 Reductive \(k\)-groups

We now recall the construction of some important compact open subgroups of \(G\) (which are called, at least when \(G\) is semisimple, connected and simply-connected, parahoric subgroups).

For any \(k\)-split torus \(S\) of \(G\), let \(X_*(S)\) be the group of \(k\)-characters of \(S\), \(X_*(S)\) the group of \(k\)-cocharacters of \(S\), \(V(S)\) the real vector space \(V(S) = X_*(S) \otimes_{\mathbb{Z}} \mathbb{R}\). Let \(T\) be a maximal \(k\)-split torus of \(G\) so that \(\dim(T) = k\)-rank(\(G\)). Let \(N\) and \(Z\) be respectively the normalizer and centralizer of \(T\) in \(G\), and \(\Phi\) be the root system of \(G\) relative to \(T\). For any root \(\alpha \in \Phi\), let \(U_{\alpha}\) be the corresponding root subgroup.

The group \(G\) is generated by \(N\) and these root groups \(U_{\alpha}\) [1]. For any \(u\) in \(U_{\alpha}\), \(u \neq 1\), there exists a unique element

\[ m(u) \in N \cap U_{-\alpha}uU_{-\alpha}. \]

The image of \(m(u)\) in the group \(N/Z\) is the reflection \(s_{\alpha}\) associated with the root \(\alpha\). We denote by \(^W V\) the group generated by these reflections \(s_{\alpha}\), \(\alpha \in \Phi\), and call it the spherical Weyl group (associated to \(T\)). When \(G\) is connected one has \(^W V = N/Z\).

The normalizer \(N\) acts linearly on the real vector space \(V(T)\). Choose an \(N\)-invariant euclidean structure on \(V(T)\). There is a unique morphism \(\nu\) of the group \(Z\) into the vector space \(V(T)\) given by the formula

\[ \chi(\nu(z)) = -\omega(\chi(z)), \]
for all \( z \in \mathbb{Z} \) and \( \chi \in X^*(\mathbb{Z}) \) where on the left-hand side \( \chi \) is seen as a linear form on \( V(T) \).

Hence \( \mathbb{Z} \) acts by translation via \( \nu \) on the affine space \( E \) underlying \( V(T) \). Since \( \mathbb{N}/\mathbb{Z} \) is a finite group, one has \( H^2(\mathbb{N}/\mathbb{Z}, V(T)) = 0 \) and hence, this action extends to a morphism \( \nu : \mathbb{N} \to \text{Aff}(E) \). Such an extension is unique up to a translation. The hyperplane \( H^{\alpha}(u) \) fixed by \( \nu(m(u)) \) is defined by the equation \( \alpha(x) + \varphi_{\alpha}(u) = 0 \) for some \( \varphi_{\alpha}(u) \in \mathbb{R} \). For \( x \in E \), we introduce the set

\[
U_{\alpha,x} = \{ u \in U_{\alpha} \mid u = 1 \text{ or } \alpha(x) + \varphi_{\alpha}(u) \geq 0 \}.
\]

By [5], \( U_{\alpha,x} \) is in fact a subgroup. We also set \( N_x = \{ n \in \mathbb{N} \mid \nu(n)(x) = x \} \), which is clearly a subgroup.

Let \( K_x \) denote the subgroup of \( G \) generated by \( N_x \) and \( U_{\alpha,x} \), \( \alpha \in \Phi \). The subgroup \( K_x \) is a compact open subgroup of \( G \).

2.3 Bruhat–Tits buildings

The Bruhat–Tits building \( X_G \) of \( G \) is now defined to be the quotient of \( G \times E \) by the equivalence relation:

\[
(g, x) \sim (h, y) \iff \exists n \in \mathbb{N} \text{ such that } y = \nu(n)x \text{ and } g^{-1}hn \in K_x.
\]

This building is modeled on \( (E, W) \) where \( W \) is the affine Weyl group i.e. the group generated by the affine reflections \( \nu(m(u)) \) with \( u \in U_{\alpha}, u \neq 1 \) and \( \alpha \in \Phi \).

The apartments of \( X_G \) are parametrized by maximal \( k \)-split tori of \( G \): the apartment \( A^T \) of \( X_G \) corresponding to the torus \( T' = gTg^{-1} \) for some \( g \in G \) is the image of \( g \times E \) in \( X_G \).

The construction of \( X_G \) does not depend on the choice of a maximal \( k \)-split torus \( T \).

The \( G \)-action by left translations on the first factor of the product \( G \times E \) induces an isometric action of \( G \) on \( X_G \), which is proper and cocompact. The stabilizers in \( G \) of points in \( X_G \) are the conjugates of the subgroups \( K_x, x \in E \). Moreover, the kernel of this action is precisely the maximal normal compact subgroup of \( G \). When \( G \) is connected and simply connected, the action of \( G \) on \( X_G \) preserves the type of the facets.

According to [20, 2.1], the Bruhat–Tits building can be characterized as in the following proposition:
PROPOSITION 2.1 ([20]). The Bruhat–Tits building $X_G$ of $G$ is the unique $G$-set containing a subset $\mathcal{A}$ normalized by $N$ such that

- as an $N$-set, $\mathcal{A}$ is isomorphic to $E$,
- every $G$-orbit in $X$ meets $\mathcal{A}$,
- for each $x \in \mathcal{A} \cong E$, the stabilizer of a point $x$ contains $K_x$.

Uniqueness means that any $G$-set satisfying the above three properties is $G$-isomorphic to $X_G$. The $G$-isomorphism is unique only up to a translation of $X_G$. The vector space $V_0$ of translations of $X_G$ is equal to $V(S_0)$ where $S_0$ is the maximal $k$-split torus of the center of $G$.

2.4 Polar decomposition for $G$

We now recall the polar decomposition (also called Cartan decomposition) for the group $G$. This decomposition is an algebraic corollary of the following geometric fact: $G$ acts strongly transitively on the building $X_G$ i.e. $G$ acts transitively on the set of all pairs $(C, \mathcal{A})$ where $C$ is a chamber and $\mathcal{A}$ is an apartment containing $C$.

Choose a positive root system $\Phi^+$ in $\Phi$ and set

$$Z^+ = \{ z \in Z \mid \omega(n_\alpha z) \leq 0, \forall \alpha \in \Phi^+ \},$$

where $n_\alpha$ is a positive integer such that, for every root $\alpha \in \Phi^+$, the multiple $n_\alpha \alpha$ extends as a character of $Z$.

We also choose a special point $x$ contained in the apartment $\mathcal{A}_T$.

PROPOSITION 2.2 ([4]). For any non-Archimedean local field $k$ and any reductive $k$-group $G$, we have

$$G = K_x Z^+ K_x.$$  

The special case of the above decomposition when $G = \text{GL}(n, k)$ has the following interpretation, when we consider the action of $G$ on the set of all ultrametric norms on $k^n$.

Recall that a norm $N$ on $k^n$ is called ultrametric if

$$N(x + y) \leq \max(N(x), N(y)) \quad \text{for all} \quad x, y \in k^n.$$  

Noting that $K_x$ is any conjugate of $\text{GL}(n, \mathcal{O})$ for the valuation ring $\mathcal{O}$ of $k$ and that $Z^+$ is a conjugate of the semigroup consisting of all diagonal matrices in valuation decreasing order, Proposition 2.2 for $\text{GL}(n, k)$ implies the following fact.
FACT 2.3 ([7, Proposition 1.3]). For any two ultrametric norms $N_1$ and $N_2$ on $k^n$ there exists a basis of $k^n$ with respect to which both of $N_1$ and $N_2$ are diagonal i.e. of the form $N(x_1, \ldots, x_n) = \sup_{1 \leq i \leq n} (\alpha_i |x_i|)$ with $\alpha_i > 0$.

3 Structure of Symmetric Spaces

We collect in this section a few preliminary facts on symmetric spaces due to Helminck and Wang in [9] and [8].

Let $k$ be a field with $\text{char}(k) \neq 2$, $G$ a connected reductive $k$-group, $\sigma$ a $k$-involution of $G$ and $H$ an open $k$-subgroup of $G^\sigma$.

3.1 Existence of $(k, \sigma)$-split tori

Recall that a $k$-torus $S$ of $G$ is said to be $(k, \sigma)$-split if it is $k$-split and $\sigma(g) = g^{-1}$ for all $g$ in $S$.

Here is a criterion for the existence of a $(k, \sigma)$-split torus in $G$ [9, Proposition 4.3].

LEMMA 3.1 ([9]). The following are equivalent:

(a) Every $(k, \sigma)$-split torus of $G$ is trivial.
(b) Every $k$-split torus of $G$ is pointwise fixed by $\sigma$.
(c) Every minimal normal isotropic $k$-subgroup of $G$ is pointwise fixed by $\sigma$. □

3.2 Finiteness of $(k, \sigma)$-split tori

We will not need the whole description of the $H$-conjugacy classes of maximal $(k, \sigma)$-split tori of $G$.

We will only need the following proposition, which can be found in (4.5), (10.3), (6.10) and (6.16) of [9].

PROPOSITION 3.2 ([9]).

(a) Any maximal $k$-split torus of $G$ containing a maximal $(k, \sigma)$-split torus of $G$ is $\sigma$-invariant.
(b) Any two maximal $(k, \sigma)$-split tori of $G$ are conjugate to each other by an element of $G$.
(c) If $k$ is a local field, the number of $H$-conjugacy classes of maximal $(k, \sigma)$-split tori of $G$ is finite. □

Hence the maximal $(k, \sigma)$-split tori of $G$ have the same dimension, which is defined to be the $k$-rank of $G/H$. 

Downloaded from https://academic.oup.com/imrn/article-abstract/doi/10.1093/imrn/rnm121/685591 by guest on 30 October 2018
3.3 Finiteness of $\sigma$-invariant $k$-split tori

Once again, we will not need the precise description of the $H$-conjugacy classes of $\sigma$-invariant maximal $k$-split tori of $G$, but only need the following proposition.

Claim (a) below is a straightforward consequence of [9, Proposition 2.3] applied to the centralizer of $T$. For other claims, we refer to Proposition 2.3, Lemma 2.4 and Corollary 6.16 of [9]. We recall that every maximal $k$-split torus of $G$ is contained in a minimal parabolic $k$-subgroup $P$ of $G$.

**Proposition 3.3 ([9]).**

(a) Any maximal $\sigma$-invariant $k$-split torus $T$ of $G$ is a maximal $k$-split torus of $G$.

(b) Any minimal parabolic $k$-subgroup $P$ of $G$ contains a maximal $\sigma$-invariant $k$-split torus of $G$, unique up to conjugacy by $H \cap R_u(P)$.

(c) If $k$ is a local field, the number of $H$-conjugacy classes of minimal parabolic $k$-subgroups is finite. Hence the number of $H$-conjugacy classes of maximal $\sigma$-invariant $k$-split tori of $G$ is finite as well.

□

When $k$ is local with $\text{char}(k) = 0$, the claims (c) in both Propositions 3.2 and 3.3 are also consequences of the following theorem of Borel and Serre: for every $k$-group $L$ and its $k$-subgroup $M$, the number of $L$-orbits in the $k$-points of $L/M$ is finite [19, III.4.4 th. 5].

4 KAH Decomposition

To prove in Theorem 1.1, we first interpret it in geometric terms, which is possible using the Bruhat–Tits building.

4.1 Flats, parallelism and Levi subgroups

We need a few more results on the geometry of Euclidean buildings.

Let $X$ be an Euclidean building. A flat in $X$ is a subset isometric to some Euclidean vector space. A geodesic is a one-dimensional flat. The system of apartments of $X$ is complete if it is maximal or, equivalently, if every maximal flat is an apartment. In fact, every system of apartments can be extended to a complete system of apartments. Moreover, the system of apartments is complete if and only if every geodesic of $X$ is contained in some apartment [13, Proposition 2.18]. In this case every flat in $X$ is contained in some apartment.
By [4, 2.8.4], since the field $k$ is complete, the system of apartments of the Bruhat–Tits building $X_G$ is also complete.

We now suppose that the system of apartments of $X$ is complete. Two flats $F$ and $F'$ of $X$ are called parallel if their Hausdorff distance is finite i.e. if there exists a constant $C > 0$ such that $d(y, F') \leq C$ and $d(y', F) \leq C$ for every $y \in F$, $y' \in F'$. Parallelism is an equivalence relation among flats. According to [10, 2.3.3 and 4.8.1], we have

- Two flats $F$ and $F'$ are parallel if and only if they are both contained in the same apartment $A$ and are parallel in $A \simeq E$.
- For a given flat $F$, the union of flats $F'$ parallel to $F$, which is then the union of apartments containing $F$, is a subbuilding of $X$, denoted by $X_F$.

The singular hull of a flat $F$ is the largest flat $F_s$ contained in every apartment containing $F$. A flat is singular if it is equal to its singular hull. By construction, we have $X_F = X_{F_s}$. A geodesic is regular if its singular hull is an apartment.

For the Bruhat–Tits building $X = X_G$ of a reductive $k$-group $G$, one can describe the subbuilding $X_F$ as the Bruhat–Tits building $X_L$ associated to some Levi subgroup $L$ of $G$ [16, 3.10], which we explain below. A Levi $k$-subgroup $L$ of $G$ is the centralizer $Z(S)$ of some $k$-split torus $S$ of $G$. A $k$-split torus $S$ in $G$ is called singular if it is equal to the maximal $k$-split torus of the center of some Levi subgroup of $G$. Equivalently, a $k$-split torus is singular if it is either a maximal $k$-split torus or an intersection of maximal $k$-split tori. This gives a bijection between the Levi $k$-subgroups of $G$ and the singular $k$-split tori of $G$. The singular hull of a $k$-split torus $S$ is the smallest singular $k$-split torus containing $S$.

Let $L$ be a Levi $k$-subgroup of $G$. Note that any maximal $k$-split torus of $L$ is also a maximal $k$-split torus of $G$. According to [5, 4.2.17], the union of the apartments $A_T$ of $X_G$ associated to the maximal $k$-split tori $T$ of $L$ is a sub-building isometric to the Bruhat–Tits building $X_L$ of $L$. This sub-building is also denoted by $X_L$ by abuse of notation. One can also check this claim using the characterization (2.1) of the Bruhat–Tits buildings.

We can summarize the above discussion in the following proposition.

**Proposition 4.1** ([5], [10], [16]). Let $k$ be a non-Archimedean local field and $G$ a reductive $k$-group.

(a) For each singular flat $F$ in $X_G$, there exists a unique singular $k$-split torus $S$ of $G$ such that $X_F = X_{Z(S)}$. This induces a bijection between the set of the parallelism classes of singular flats of $X_G$ and the set of all singular $k$-split tori of $G$. 
The parallel singular flats associated to a singular $k$-split torus $S$ are exactly the $V(S)$-orbits in $X_{Z(S)}$. □

REMARK 4.2.
— Every apartment of $X_{Z(S)}$ is associated to a maximal $k$-split torus of the Levi subgroup $Z(S)$. Not all of them contain $F$.
— The group $Z(S)$ acts cocompactly on the set $X_{Z(S)}/V(S)$ of flats parallel to $F$, since it already acts co-compactly on the building $X_{Z(S)}$.

4.2 $\sigma$-Flats

For the rest of Section 4, we suppose as in our initial setting that $k$ is a non-Archimedean local field with $\text{char}(k) \neq 2$, $G$ is a connected reductive $k$-group, $\sigma$ is a $k$-involution of $G$ and that $H$ is an open $k$-subgroup of $G$.

We first remark that the involution $\sigma$ induces an involution, also denoted by $\sigma$, of the Bruhat–Tits building $X_G$. In fact, let $G' = \langle \sigma \rangle \ltimes G$ be the semidirect product of the group $\langle \sigma \rangle$ of order 2 with $G$. This is a reductive $k$-group whose Bruhat–Tits building $X_{G'}$ is the same as $X_G$. That is why $G'$ acts on $X_G$.

The following definition allows us to restate Theorem 1.1 in a geometric way.

DEFINITION 4.3. A $\sigma$-invariant flat of $X_G$ on which $\sigma$ has only one fixed point is called a $\sigma$-flat. A $\sigma$-flat in $X_G$ of maximal dimension is called a $\sigma$-apartment.

We will see below that the maximal dimension of a $\sigma$-flat in $X_G$ is equal to the $k$-rank of $G/H$. Note that a maximal $\sigma$-flat is not always a $\sigma$-apartment: for instance, if $k$-rank$(G) = k$-rank$(H)$, there exists a chamber in $X_G$ of which every point is $\sigma$-fixed. Certainly each point in this chamber is a maximal $\sigma$-flat but not of maximal dimension unless the $k$-rank of $G/H$ is zero.

This shows that the union of all $\sigma$-apartments of $X_G$ is not equal to $X_G$ in general. However, we will see in Theorem 4.7 that this is not far from being true.

We will need the following two lemmas. The first one is analogous to Lemma 3.1.

LEMMA 4.4.
(a) The following are equivalent:

(i) The $k$-rank of $G/H$ is equal to 0.
(ii) Every $\sigma$-apartment of $X_G$ is a point.
(iii) The involution $\sigma$ acts trivially on $X_G$.

(b) Any point $x \in X_G$ with $\sigma(x) \neq x$ lies in a one-dimensional $\sigma$-flat. □
PROOF. (i) $\Rightarrow$ (ii) Let $\mathcal{F}$ be a $\sigma$-flat of dimension 1. Note that the singular hull $\mathcal{F}'$ of $\mathcal{F}$ is a $\sigma$-invariant flat of $X_G$. By Proposition 4.1, there exists a singular $k$-split torus $S$ such that $X_{\mathcal{F}'} = X_{Z(S)}$. This torus $S$ and its centralizer $L$ is $\sigma$-invariant. The building $X_L$ is isometric to a product $X_L^{\text{ess}} \times V(S)$. The group $S$ acts on this product by translations on the Euclidean factor $V(S)$. Since the action of $\sigma$ on $V(S) \simeq \mathcal{F}'$ is nontrivial, the action of $\sigma$ on $S$ is also nontrivial. It follows that the $k$-rank of $G/H$ is nonzero.

(ii) $\Rightarrow$ (iii) For $x \in X_G$, suppose $\sigma(x) \neq x$. We want to prove that there exists a one-dimensional $\sigma$-flat $\mathcal{F}$ containing $x$. This will also prove the claim (b). Since there exists an apartment containing both $x$ and $\sigma(x)$, there exists a geodesic $\mathcal{F}_0$ containing both $x$ and $\sigma(x)$. The points $x$ and $\sigma(x)$ cut this geodesic into three pieces: two rays $\mathcal{F}_-$ and $\mathcal{F}_+$ and a segment $[x, \sigma(x)]$. Set

$$\mathcal{F} = \mathcal{F}_- \cup [x, \sigma(x)] \cup \sigma(\mathcal{F}_-)$$

This path $\mathcal{F}$ is indeed a geodesic since it is locally a geodesic and $X_G$ is a CAT(0)-space. By construction, $\mathcal{F}$ is also $\sigma$-invariant. Since $\sigma(x) \neq x$, the geodesic $\mathcal{F}$ is a one-dimensional $\sigma$-flat, as desired.

(iii) $\Rightarrow$ (i) Let $S$ be a maximal $(k, \sigma)$-split torus of $G$ and $T$ a maximal $k$-split torus of $G$ containing $S$. By Proposition 3.2 (a), the torus $T$ is $\sigma$-invariant. Hence the corresponding apartment $\mathcal{A}_T$ is also $\sigma$-invariant. If the $k$-rank of $G/H$ is nonzero, the action of $\sigma$ on $T$ is nontrivial. Hence the action of $\sigma$ on $\mathcal{A}_T$ is also nontrivial. This proves the claim.

4.3 $\sigma$-Apartments

Note that a maximal $(k, \sigma)$-split torus of $G$ may not be a singular $k$-split torus. Nevertheless, we have the following assertion analogous to Proposition 4.1.

**Lemma 4.5.**

(a) For any $\sigma$-apartment $\mathcal{F}$ of $X_G$, there exists a unique maximal $(k, \sigma)$-split torus $R$ of $G$ such that $X_{\mathcal{F}} = X_{Z(R)}$. This induces a bijection between the set of all parallelism classes of $\sigma$-apartments of $X_G$ and the set of all maximal $(k, \sigma)$-split tori of $G$.

(b) For a maximal $(k, \sigma)$-split torus $R$ of $G$, the parallel $\sigma$-apartments $\mathcal{F}$ associated to $R$ are exactly the $V(R)$-orbits in the building $X_{Z(R)}$ and the subgroup $H \cap Z(R)$ acts cocompactly on the quotient building $X_{Z(R)}/V(R)$.

(c) Every apartment of $X_G$ containing a $\sigma$-apartment is $\sigma$-invariant. □
As an immediate corollary, we obtain:

**Lemma 4.6.** The $k$-rank of $G/H$ is equal to the dimension of the $\sigma$-apartments of $X_G$. $\square$

**Proof of Lemma 4.5.** We will prove (a), (b) and (c) simultaneously.

Let $\mathcal{F}$ be a $\sigma$-apartment of $X_G$. Let $\mathcal{F}^\sigma$ be the singular hull of $\mathcal{F}$ and $S$ the unique singular $k$-split torus of $G$ such that $X_{Z(S)} = X_{\mathcal{F}^\sigma}$ (see Proposition 4.1). Note that the torus $S$ and its centralizer $L = Z(S)$ are also $\sigma$-invariant. Let $R$ be the maximal $(k, \sigma)$-split torus of $S$. Again by Proposition 4.1, the vector space $V(S)$ acts simply transitively on $\mathcal{F}^\sigma$. Since this action is $\sigma$-equivariant, and $\mathcal{F}$ is a $\sigma$-flat of maximal dimension in $\mathcal{F}^\sigma$, this flat $\mathcal{F}$ is a $V(R)$-orbit.

Since $\mathcal{F}^\sigma$ is the singular hull of $\mathcal{F}$, the torus $S$ is also the singular hull of $R$. It follows that $L$ is equal to the centralizer of $R$ and hence one has $X_{Z(R)} = X_{\mathcal{F}^\sigma}$.

By the maximality of the $\sigma$-flat $\mathcal{F}$, the quotient building $X_L/V(R)$ contains no one-dimensional $\sigma$-flat. Hence, by Lemma 4.4 (i), $L/R$ contains no nontrivial $(k, \sigma)$-split torus and hence the torus $R$ is a maximal $(k, \sigma)$-split torus in $L$. Since $L$ is the centralizer of $R$, the torus $R$ is also a maximal $(k, \sigma)$-split torus of $G$. To show the uniqueness of $R$, let $R'$ be any maximal $(k, \sigma)$-split torus of $G$ such that $X_{Z(R')} = X_{\mathcal{F}^\sigma}$. This torus $R'$ is contained in $S$ and hence in $R$ as well. By the maximality of $R'$, $R' = R$. This shows the first part of the claim (a).

By Lemma 3.1 (c), the group $H \cap L$ acts co-compactly on $X_L/V(R)$. This, together with the previous discussion, proves (b). By Lemma 4.4 (iii), the action of $\sigma$ on the building $X_L/V(R)$ is trivial. Therefore every flat containing $\mathcal{F}$ is $\sigma$-invariant. This proves (c).

To finish the proof of (a), letting $R$ be a maximal $(k, \sigma)$-split torus of $G$, we want to prove that there exists a $\sigma$-apartment $\mathcal{F}$ of $X_G$ such that $X_{Z(R)} = X_{\mathcal{F}^\sigma}$ and we want to prove that such an apartment is unique up to parallelism.

The singular hull $S$ of $R$ and its centralizer $L = Z(R)$ are $\sigma$-invariant. The associated building $X_L$ is also $\sigma$-invariant, and the action of the vector space $V(S)$ on $X_L$ commutes with $\sigma$. Hence the $V(R)$-orbits in $X_L$ are $\sigma$-flats which are parallel to one another. Let $\mathcal{F}$ be one of these $\sigma$-flats. Since $R$ is maximal, the reductive $k$-group $L/R$ contains no nontrivial $(k, \sigma)$-split torus.

By Lemma 4.4 (iii), $\sigma$ acts trivially on the quotient building $X_L/V(R)$. Hence $\mathcal{F}$ is a $\sigma$-flat of maximal dimension, i.e. a $\sigma$-apartment. Since the torus $S$ is the singular hull of $R$, the $V(S)$-orbit $\mathcal{F}^S$ containing $\mathcal{F}$ is the singular hull of $\mathcal{F}$ and we have $X_{Z(R)} = X_{\mathcal{F}^\sigma}$.

Finally, if $\mathcal{F}'$ is any $\sigma$-apartment such that $X_{Z(R)} = X_{\mathcal{F}'}$, then $\mathcal{F}'$ is contained in a $V(S)$-orbit and hence in a $V(R)$-orbit in $X_L$. Therefore since $\mathcal{F}'$ is of maximal dimension, $\mathcal{F}'$ is equal to a $V(R)$-orbit in $X_L$. Hence $\mathcal{F}'$ is parallel to $\mathcal{F}$. This completes the proof of (a).
4.4 Geometric interpretation

Here is a geometric reformulation of Theorem 1.1.

For $C > 0$, a subset $Y$ of a metric space $X$ is $C$-dense if every point of $X$ has distance at most $C$ from $Y$. A subset $Y$ is quasi-dense in $X$ if it is $C$-dense for some $C > 0$.

**Theorem 4.7.** Let $k$ be a non-Archimedean local field with $\text{char}(k) \neq 2$, $G$ a connected reductive $k$-group and $\sigma$ a $k$-involution of $G$. The union of all $\sigma$-apartments is quasi-dense in the Bruhat–Tits building $X_G$. □

We begin by proving the following lemma:

**Lemma 4.8.** Either $\sigma$ acts trivially on $X_G$ or the set $\{x \in X_G \mid \sigma(x) \neq x\}$ is quasi-dense in $X_G$. □

**Remark 4.9.** When the residual characteristic of $k$ is not 2, according to Prasad and Yu [15], the set $X_G^\sigma$ of $\sigma$-fixed points can be identified with the Bruhat–Tits building $X_H$ of $H$, when the action of $\sigma$ is nontrivial on $X_G$. This gives a proof of Lemma 4.8 in this case. We present below a short proof of the above lemma assuming only that $\text{char}(k) \neq 2$.

**Proof of Lemma 4.8.** Suppose that the action of $\sigma$ on $X_G$ is nontrivial. We will show that there exists a constant $C > 0$ such that, for every $x \in X_G$, the ball $B(x, C)$ is not pointwise fixed by $\sigma$.

Suppose not. Then there exists a sequence $\{x_n \in X_G\}$ such that the balls $B(x_n, n)$ are pointwise fixed by $\sigma$. We may - and shall - assume that for a fixed $x_0 \in X_G$, $x_n = g_n x_0$ for some $g_n \in G$. Then the element $\sigma_n = g_n \sigma g_n^{-1}$ is an involutive automorphism of $G$ which acts trivially on $B(x_0, n)$. Hence the sequence $\sigma_n$ subconverges to the identity in $\text{Aut}(G)$. Hence any compact open subgroup of $\text{Aut}(G)$ contains $\sigma_n$ for all sufficiently large $n$. On the other hand, if $\text{char}(k) = 0$, then $\text{Aut}(G)$ contains a compact open subgroup which is torsion free. If the residual characteristic of $k$ is $p \neq 2$, the group $\text{Aut}(G)$, as any group $G'$ of $k$-points of a $k$-group $G'$, contains a compact open subgroup which is a pro-$p$-group. Since a pro-$p$-group has no elements of order 2, the order of $\sigma_n$ is 2, and we obtain a contradiction in either case. □

**Proof of Theorem 4.7.** We want to prove that there exists a constant $C_G > 0$ such that every point $x \in X_G$ has distance at most $C_G$ from some $\sigma$-apartment $F$ of $X_G$.

We argue by induction on the dimension of $G$. Writing, as in Section 2, $X_G \cong X_G^{\text{ess}} \times V(S_0)$ where $S_0$ is the maximal $k$-split torus of the center of $G$, we may - and shall - assume that $G$ is semisimple.
If $\sigma$ acts trivially on $X_G$ then every point of $X_G$ is a $\sigma$-apartment in which case our claim trivially holds. Hence we assume that $\sigma$ does not act trivially on $X_G$. By Lemma 4.8 and Lemma 4.4 (b), we may then assume that $x$ lies in a one-dimensional $\sigma$-flat $F$. Then $x$ belongs to the subbuilding $X_{\mathfrak{F}}$, where $\mathfrak{F}$ is the singular hull of $F$. By Proposition 4.1 and Lemma 4.5, the subbuilding $X_{\mathfrak{F}}$ is equal to the building $X_L$ associated to some $\sigma$-invariant Levi-subgroup $L \subseteq G$ such that every $\sigma$-apartment in $X_L$ is also an $\sigma$-apartment in $X_G$. We apply our induction hypothesis to the reductive subgroup $L$ to conclude.

Note that the distance on the building $X_G^{ess}$ is unique only up to some scalar factors, one for each quasi-simple isotropic normal $k$-subgroup of $G$. The constant $C_G$ will depend on this normalization of those scalar factors. The same is true for $L$.

Each $\sigma$-invariant Levi subgroup $L$ gives rise to some constant $C_L$. This constant $C_L$ depends only on the $H$-conjugacy class of $L$.

To obtain a finite upper bound for these $C_L$, we need to know that there are only finitely many $H$-conjugacy classes of $\sigma$-invariant Levi subgroup of $G$. Since a $k$-split torus contains only finitely many singular $k$-split sub-tori, this assertion is a direct consequence of the finiteness of the number of $H$-conjugacy classes of maximal $\sigma$-invariant $k$-split tori of $G$ (Proposition 3.3).

4.5 Orbits of $(k, \sigma)$-split tori in $X_G$

The following corollary is the link between Theorem 1.1 and Theorem 4.7.

As in the introduction, we choose maximal $(k, \sigma)$-split tori $A_1, \ldots A_n$, which are representatives of $H$-conjugacy classes of all maximal $(k, \sigma)$-split tori of $G$ (cf. Proposition 3.2). Let $A$ be the union of the groups of $k$-points $A_i$, $1 \leq i \leq n$.

**COROLLARY 4.10.** Let $k$ be a non-Archimedean local field with $\text{char}(k) \neq 2$, $G$ a connected reductive $k$-group, $\sigma$ a $k$-involution of $G$ and $H$ an open $k$-subgroup of $G^\sigma$.

For any fixed $x_0 \in X_G$, there exists a constant $C > 0$ such that for all $x \in X_G$, there exist $h \in H$ and $1 \leq i \leq n$ with

$$d(hx, A_ix_0) \leq C.$$

In other words, the union of the $H$-orbits meeting $Ax_0$ is quasi-dense in $X_G$. □
PROOF. By Theorem 4.7, the set of $\sigma$-apartments are $C_0$-dense in $X_G$ for some $C_0 > 0$. Hence $d(x,x_1) < C_0$ for some $x_1$ contained in a $\sigma$-apartment $F$. Then by Lemma 4.5, $x_1$ is contained the sub-building $X_{Z(S)}$ of the centralizer of a maximal $(k,\sigma)$-split torus $S$ of $G$. By Proposition 3.2 (c), $S$ is conjugate to one of $A_i$ by an element of $H$ and hence for some $h \in H$, $hx_1 \in X_{Z(A_i)}$.

Fix a $\sigma$-apartment $F_i$ associated to $A_i$ as in Lemma 4.5 for each $1 \leq i \leq n$ and let $e_i$ denote the Hausdorff distance between $F_i$ and $A_ix_0$. By Lemma 4.5, the group $H \cap Z(A_i)$ acts co-compactly on the quotient building $X_{Z(A_i)}/V(A_i)$. In other words, there is $d_i > 0$ such that any point in $X_{Z(A_i)}$ is within distance $d_i$ from any $\sigma$-apartment in $X_{Z(A_i)}$ parallel to $F_i$, up to translation by $H \cap Z(A_i)$.

Therefore one has

$$d(h'hx_1,F_i) < d_i$$

for some $h' \in H \cap Z(A_i)$.

Hence one gets

$$d(h'hx,A_ix_0) \leq d(x,x_1) + d(h'hx_1,F_i) + d(F_i,A_ix_0) \leq C_0 + d_i + e_i.$$

It remains to put $C = C_0 + \max_{1 \leq i \leq n}(d_i + e_i)$. ■

PROOF OF THEOREM 1.1. It is now very easy to conclude. Fixing a point $x_0 \in X_G$, let $C > 0$ be a constant given by Corollary 4.10 and $K$ the compact subset of $G$ given by

$$K = \{ k \in G \mid d(x_0,kx_0) \leq C \}.$$

For any $g \in G$, we apply Corollary 4.10 to $x = g^{-1}x_0$ to obtain elements $h \in H$, $a \in \cup_{i=1}^{n}A_i$ such that

$$d(hx,a^{-1}x_0) \leq C,$$

or, equivalently,

$$d(x_0,gh^{-1}a^{-1}x_0) \leq C.$$

In other words, we have $g = kah$ for some $k \in K$. ■

5 Examples

In order to put our polar decomposition in perspective, we now recall some well-known examples.
5.1 The real case

We first discuss the Archimedean case $k = \mathbb{R}$ and recall the proof of the following basic fact:

**FACT 5.1.** Every nondegenerate quadratic form $q$ on the Euclidean space $\mathbb{R}^n$ can be put into diagonal form by an orthogonal base change. □

**PROOF.** Choose a point $e_1$ on the Euclidean unit sphere in $\mathbb{R}^n$ where $q$ achieves the maximum. Note that the Euclidean orthogonal of $e_1$ is also orthogonal for $q$. Hence we can use an induction argument. ■

**REMARK 5.2.** Fact 5.1 is a special case of the polar decomposition $G = KAH$ for a real symmetric space $G/H$ with $G = \text{GL}(n, \mathbb{R})$, with $K = O(n)$, with $A$ the subgroup of diagonal matrices and with $H = O(p, n - p)$ for any $0 \leq p \leq n$: Write $q = q_0 \circ g^{-1}$ with $q_0 = x_1^2 + \cdots + x_p^2 - x_{p+1}^2 - \cdots - x_n^2$ and $g \in G$. If we write $g = kah \in KAH$, then the quadratic form $q \circ k = q_0 \circ a^{-1}$ is diagonal.

We now recall more precisely the “real” polar decomposition and its proof. Let $G$ be a connected reductive $\mathbb{R}$-group, $\sigma$ an $\mathbb{R}$-involution of $G$ and $H$ an open $\mathbb{R}$-subgroup of $G^\sigma$. Recall that an $\mathbb{R}$-involution $\theta$ of $G$ is called Cartan if the group $K = G^\theta$ of $\theta$-fixed points is a maximal $\mathbb{R}$-anisotropic subgroup of $G$.

The following facts are well-known [18]:

— There exists a Cartan involution $\theta$ of $G$ which commutes with $\sigma$, i.e. such that $\sigma \theta = \theta \sigma$.

— A maximal $(\mathbb{R}, \sigma)$-split torus $A$ of the group $H' = G^\sigma$ of $\sigma \theta$-fixed points is a maximal $\mathbb{R}$-split torus of $H'$ as well as a maximal $(\mathbb{R}, \sigma)$-split torus of $G$.

Moreover, all maximal $(\mathbb{R}, \sigma)$-split tori of $G$ are $H$-conjugate.

Letting $K = G^\theta$ and $A$ a maximal $(\mathbb{R}, \sigma)$-split torus of the group $H'$, the polar decomposition for $G/H$ is given as follows:

**PROPOSITION 5.3** ([18]). We have $G = KAH$ with $K = K_\mathbb{R}$, with $A = A_\mathbb{R}$ and $H = H_\mathbb{R}$. □

We recall here a sketch of proof to emphasize both analogies and differences with our proof in the non-Archimedean case.

**Sketch of proof** As in the proof of Fact 5.1, the proof uses a minimizing argument. Let $g \in G$. Fix a base point $x_0 = K/K$ in the Riemannian symmetric space $X_0 = G/K$ and and set $x = g^{-1}x_0$. Let $y = h^{-1}x_0$, with $h \in H$, be the nearest point to $x$ on the totally geodesic sub-manifold $X_H = H/(H \cap K)$. The geodesic from $x_0$ to $hx$ is orthogonal to $X_H$. Hence
the point $hx$ is in the symmetric subspace $X_{H'} = H'/(H' \cap K)$ “orthogonal at $x_0$” to $X_H$. Therefore we have $x_0 = h'hx$ with $h' \in H'$, or, in other words, $g = kh'h$ with $k \in K$. Using the Cartan decomposition $H' = (H \cap K)A(H \cap K)$ for the subgroup $H'$, we then obtain $g \in KAH$, as desired. 

5.2 Quadratic forms

We now discuss the diagonalization of quadratic forms in the non-Archimedean case. The following fact is analogous to Fact 5.1:

**Fact 5.4** ([7, Proposition 4.19]). Let $k$ be a non-Archimedean local field of residual characteristic not 2. Every nondegenerate quadratic form on $k^n$ can be put into diagonal form by a base change preserving the sup norm.

Recall that the stabilizer of the sup norm $|x| = \sup_{1 \leq i \leq n} |x_i|$ is the maximal compact subgroup $K_0 = \text{GL}(n, \mathcal{O}) \subset \text{GL}(n, k)$ where $\mathcal{O}$ is the valuation ring of $k$.

**Proof.** Choose a point $e_1$ on the unit ball $\mathcal{O}^n$ where $|q|$ is maximum. Note that $e_1$ is primitive, i.e. $ke_1 \cap \mathcal{O}^n = \mathcal{O}e_1$. Hence $e_1$ can be completed to a basis, say $(e_1, \ldots, e_n)$, of $\mathcal{O}^n$. Write $q(\sum x_ia_i) = \sum a_{ij}x_ix_j$ where the matrix $b = (a_{ij})$ is symmetric. One can assume $a_{11} = 1$. By the maximality of $|q(e_1)| = a_{11} = 1$, we have $|q(e_i)| = |a_{1,i}| \leq 1$ for each $i$. It follows from $|q(e_1 + e_i)| \leq 1$ that $2|a_{1,i}| \leq 1$ for each $i$. Since the residual characteristic is not 2, we have $|a_{1,i}| \leq 1$. Therefore the $n$-tuple $(e_1, e_2', \ldots, e_n')$ with $e_i' = e_i - a_{1,i}e_1$ is also a basis of $\mathcal{O}^n$ and $e_2', \ldots, e_n'$ are orthogonal to $e_1$. We then use an induction argument to conclude.

We may translate Fact 5.4 in terms of our polar decomposition. Let $q_0$ be a nondegenerate diagonal quadratic form on $k^n$, set $G = \text{GL}(n)$, $K_0 = \text{GL}(n, \mathcal{O})$, $A_0$ the $k$-group of diagonal matrices, $H = \mathcal{O}(q_0)$, so that $X = G/H$ is the space of nondegenerate quadratic forms and $X = G/H$ is the space of quadratic forms $G$-equivalent to $q_0$. The subset of diagonal quadratic forms is $X_{\text{diag}} = X \cap A_0q_0$. Fact 5.4 gives the equality

$$X = K_0X_{\text{diag}} \text{ or } G = K_0(A_0H)_k.$$ 

The set $(A_0H)_k$ is a finite union of double classes $A_0g_iH$, where the set of indices $i$ is given by $(k'/k^{2^n})$. Letting $A_i = g_i^{-1}A_0g_i$, $A$ the union of $A_i$’s and $K$ the union of $K_0g_i$’s, we obtain the polar decomposition $G = KAH$ as in Theorem 1.1. Note here that $K$ is a compact subset.
REMARK 5.5. If the residual characteristic is 2 but the characteristic of $k$ is not 2, the same argument shows that there exists a compact subset $K_0$ of $\text{GL}(n, k)$ such that every nondegenerate quadratic form on $k^n$ can be put into diagonal form by a base change in $K_0$ i.e. $G = K_0(A_0H)_k$. One can easily find an example where $K_0$ cannot be chosen to be a subgroup.

5.3 The group case

The following is a well-known corollary of Proposition 2.2.

COROLLARY 5.6. Let $k$ be a non-Archimedean local field, $G$ a reductive $k$-group and $A$ a maximal $k$-split torus of $G$. Then there exists a compact subset $K$ of $G$ such that $G = KAK$. □

PROOF. We keep the same notation as in Proposition 2.2. Let $Z_c = K_x \cap Z$ be the maximal compact subgroup of $Z$. The quotient $Z/Z_c$ is an abelian group of rank $r$ and the image of $T$ in $Z/Z_c$ is a subgroup of finite index. ■

This corollary is also a special case of our polar decomposition (Theorem 1.1) for the group $G \times G$ with the involution given by $\sigma(g_1, g_2) = (g_2, g_1)$ for which $H$ is the diagonal embedding of $G$ into $G \times G$. In this example there exists only one $H$-conjugacy class of maximal $(k, \sigma)$-split tori of $G \times G$.

REMARK 5.7. Note that even in this corollary one can not always choose the compact subset $K$ to be a subgroup of $G$ because the map from $T$ to $Z/Z_c$ is not surjective in general.

5.4 All $\sigma$-apartments are useful

The following lemma with Lemma 4.5 (a) shows that all the representatives $A_i$ of $H$-conjugacy classes of maximal $(k, \sigma)$-split tori of $G$ are useful in our polar decomposition (Theorem 1.1 or 4.7).

LEMMA 5.8. Let $k$ be a non-Archimedean local field with $\text{char}(k) \neq 2$, $G$ a connected reductive $k$-group, $\sigma$ a $k$-involution of $G$ and $H$ an open $k$-subgroup of $G^\sigma$.

Let $\mathcal{F}, \mathcal{F}_1, \ldots, \mathcal{F}_\ell$ be maximal $\sigma$-apartments (see Definition 4.3) of $X_G$ such that

$$\sup_{x \in \mathcal{F}} d(x, \bigcup_{1 \leq i \leq \ell} H.\mathcal{F}_i) < \infty.$$ 

Then $\mathcal{F}$ is parallel to one of the translates $h.\mathcal{F}_i$ with $h \in H$ and $1 \leq i \leq \ell$. □
PROOF. Since there are only finitely many directions of singular flats in \( \mathcal{F} \), we can choose a \( \sigma \)-invariant geodesic \( t \mapsto c_t \) in \( \mathcal{F} \) with the same singular hull as \( \mathcal{F} \) and satisfying \( \sigma(c_t) = c_{-t} \) for all \( t \). By hypothesis we can find \( C_0 > 0 \), \( 1 \leq i \leq \ell \) and sequences \( t_n \to \infty \), \( h_n \in H \) such that
\[
d(c_{t_n}, h_n \mathcal{F}_i) \leq C_0.
\]
Applying \( \sigma \), we have
\[
d(c_{-t_n}, h_n \mathcal{F}_i) \leq C_0.
\]
Using the fact that in a CAT(0)-space, the distance function to a convex subset is a convex function, we deduce that for all \( s \in [-t_n, t_n] \)
\[
d(c_s, h_n \mathcal{F}_i) \leq C_0
\]
and that
\[
d(c_0, h_n x_i) \leq C_0
\]
where \( x_i \) denotes the unique point of \( \mathcal{F}_i \) which is \( \sigma \)-invariant. The sequence \( h_n \) remains in a compact subset of \( G \) and hence converges to an element \( h \in H \), after passing to a sub-sequence. We then have that for all \( s \in \mathbb{R} \),
\[
d(c_s, h \mathcal{F}_i) \leq C_0.
\]
Hence, by [10, 2.3.3], the geodesic \( \mathbb{G} = \{ c_t \, : \, t \in \mathbb{R} \} \) is parallel to a geodesic in \( h \mathcal{F}_i \). But then \( h \mathcal{F}_i \) is included in the subbuilding \( X_\mathbb{G} \). Since \( \mathbb{G} \) and \( \mathcal{F} \) have the same singular hull, we have \( h \mathcal{F}_i \subset X_\mathbb{G} = X_\mathcal{F} \). Therefore Lemma 4.5 implies that \( h \mathcal{F}_i \) is parallel to \( \mathcal{F} \).
