Bredon motivic cohomology of the complex numbers

Jeremiah Heller †, Mircea Voineagu, Paul Arne Østvær †

Abstract

Over the complex numbers, we compute the $C_2$-equivariant Bredon motivic cohomology ring with $\mathbb{Z}/2$ coefficients. By rigidity, this extends Suslin’s calculation of the motivic cohomology ring of algebraically closed fields of characteristic zero to the $C_2$-equivariant motivic setting.

Keywords. Motivic homotopy theory, equivariant homotopy theory, Bredon cohomology.

1 Introduction

Bredon motivic cohomology (introduced in [7] and [8]) is a generalization of motivic cohomology to the setting of smooth varieties with finite group action. Part of a larger group of motivic $C_2$-invariants, such as Hermitian K-theory and motivic real cobordism, it plays an essential role in equivariant motivic homotopy theory. One distinguishing feature is that Bredon motivic cohomology appears as the zero slice of the equivariant motivic sphere [6].

Bredon motivic cohomology is ready for concrete computations, which will be crucial for applications of the theory to other motivic and topological invariants. In this paper, we compute the Bredon motivic cohomology ring with $\mathbb{Z}/2$-coefficients. The usual methods [13], [19], [20] generalize the computations to an algebraically closed field of characteristic zero. These can be seen as a first step in understanding the largely unknown and difficult to compute Bredon cohomology ring for an arbitrary field $k$ (for partial results in this direction see [18]) as well as the $C_2$-equivariant motivic Steenrod algebra of cohomology operations.

Our computations are organized via modules over Bredon cohomology of a point. Before presenting our computations, we recall this ring and introduce some notation used to explain our results.

1.1 Bredon cohomology

In equivariant topology, Bredon cohomology plays the role that singular cohomology plays in ordinary topology. Some of its key features are that it takes a Mackey functor as coefficients, it is graded by representations, and is represented by an equivariant Eilenberg-MacLane spectrum, see [11] for details. The case of interest to us is \( G = C_2 \), in which case we write \( \sigma \) for the sign representation. The group \( \text{RO}(C_2) \) is identified with \( \mathbb{Z} \oplus \mathbb{Z} \langle \sigma \rangle \). We adopt the convention that \( \ast \) stands for an \( \text{RO}(C_2) \)-grading and we use \( \ast \) for an integer grading. For an abelian group \( A \), the Bredon cohomology with coefficients in the constant Mackey functor \( \underline{A} \) of a \( C_2 \) spectrum \( X \) is written \( \check{H}^\ast_{\text{Br}}(X, \underline{A}) \). If \( X = \Sigma^\infty X_+ \) we simply write \( \check{H}^\ast_{\text{Br}}(X, \underline{A}) := \check{H}^\ast_{\text{Br}}(\Sigma^\infty X_+, \underline{A}) \).

The Bredon cohomology ring of a point with \( \mathbb{Z}/2 \)-coefficients was originally computed by Stong in unpublished work. Written accounts can be found in [1, Appendix] and [10, Proposition 6.2]. For the corresponding computation with \( \mathbb{Z} \)-coefficients see [3, Theorem 2.8] or [5, Section 2] for recent discussion of these computations. We write

\[ \mathcal{M}^C_2 := H^\ast_{\text{Br}}(pt, \mathbb{Z}/2). \]

Let \( \mathbb{Z}/2[a, u] \) be the polynomial ring generated by elements whose degrees are \( |a| = \sigma \) and \( |u| = -1 + \sigma \). Consider \( \mathbb{Z}/2[a^{-1}, u^{-1}] \) as a graded \( \mathbb{Z}/2[a, u] \)-module and write

\[ \text{NC} := \Sigma^{2 - 2\sigma} \mathbb{Z}/2[a^{-1}, u^{-1}], \]

where \( \Sigma^{m+n\sigma} M \) denotes the shifted graded module given by \( (\Sigma^{m+n\sigma} M)^{a^{-\sigma}u} = M^{a^{-m}(u-n)\sigma} \).

From Figure 1, one sees that \( \mathcal{M}^C_2 \) consists of two cones; \( \text{NC} \) is the “negative cone”. The Bredon cohomology ring of a point is

\[ \mathcal{M}^C_2 \cong \mathbb{Z}/2[a, u] \oplus \text{NC}, \quad (1.1) \]

where the multiplicative structure is determined by the action of \( \mathbb{Z}/2[a, u] \) on \( \text{NC} \) and all products between elements in \( \text{NC} \) are trivial. Writing \( \theta \in \text{NC} \) for the element which corresponds to \( 1 \in \mathbb{Z}/2[a^{-1}, u^{-1}] \), we express elements of \( \text{NC} \) in the form \( \frac{\theta}{a^{-m}u^n} \), for \( m, n \geq 0 \).

We introduce some auxiliary \( \mathcal{M}^C_2 \)-modules. See Figure 1 for graphical depictions. Recall the universal free \( C_2 \)-space \( EC_2 \); a geometric model is \( S(\infty \sigma) = \operatorname{colim}_n S(n\sigma) \), where \( S(n\sigma) \) is the unit sphere in the \( n \)-dimensional real sign representation. The space \( EC_2 \) is defined to be the unreduced suspension of \( EC_2 \), which by definition fits into the cofiber sequence of based \( C_2 \)-spaces, \( EC_2 \to S^0 \to \tilde{EC}_2 \).

The Bredon cohomology ring of \( EC_2 \) is

\[ H^\ast_{\text{Br}}(EC_2, \mathbb{Z}/2) \cong \mathbb{Z}/2[a, u \pm 1] \]

where \( |a| = -1 + \sigma \) and \( |u| = \sigma \), see e.g., [1, Lemma 27]. Then \( H^\ast_{\text{Br}}(EC_2, \mathbb{Z}/2) \cong \mathcal{M}^C_2[u^{-1}] \) and the ring map \( \mathcal{M}^C_2 \to H^\ast_{\text{Br}}(EC_2, \mathbb{Z}/2) \) is the localization map. In other words, it is the map which sends \( u \mapsto u \), \( a \mapsto a \) and maps \( \text{NC} \) to 0.

The Bredon cohomology of \( \tilde{EC}_2 \) is

\[ \check{H}^\ast_{\text{Br}}(\tilde{EC}_2, \mathbb{Z}/2) \cong \Sigma^{2 - 2\sigma} \mathbb{Z}/2[a^{\pm 1}, u^{-1}], \]

see e.g., [1, Lemma 28]. The right-hand side is a \( \mathbb{Z}/2[a, u] \)-module and hence an \( \mathcal{M}^C_2 \)-module (elements of \( \text{NC} \) act by 0) and this isomorphism is an \( \mathcal{M}^C_2 \)-module isomorphism. The negative cone is a quotient of this module,

\[ \text{NC} \cong \Sigma^{2 - 2\sigma} \mathbb{Z}/2[a^{\pm 1}, u^{-1}]/a \mathbb{Z}/2[a, u^{-1}]. \]

The \( \mathcal{M}^C_2 \)-module map

\[ \Sigma^{2 - 2\sigma} \mathbb{Z}/2[a^{\pm 1}, u^{-1}] \to \mathcal{M}^C_2, \quad (1.2) \]

induced by \( S^0 \to \tilde{EC}_2 \), is this quotient followed by the inclusion of the negative cone into \( \mathcal{M}^C_2 \). Explicitly, it is the map

\[ \frac{\theta}{a^{m}u^n} \mapsto \begin{cases} \frac{\theta}{a^{-m}u^n} & \text{if } m \leq 0 \\ 0 & \text{if } m > 0 \end{cases} \]

where \( \theta \in \Sigma^{2 - 2\sigma} \mathbb{Z}/2[a^{\pm 1}, u^{-1}] \) denotes the element corresponding to \( 1 \in \mathbb{Z}/2[u^{-1}, x^{\pm 1}] \).
Remark 1.3. It will be convenient to have notation for certain submodules of $\tilde{H}^i_{\text{Br}}(\tilde{E}C_2, \mathbb{Z}/2)$. For $i \geq 1$, write
\[ B_i := \Sigma^2 \mathbb{Z}/2[a^{\pm 1}, u^{-1}]/(u^{-2i}). \]
This is a $\mathbb{Z}/2[a, u]$-module and hence an $\mathcal{M}_2^{C^2}$-module (elements of NC act by 0). Note that there is an identification
\[ B_i \cong \bigoplus_{a \leq 2i+1} \tilde{H}^{i+i\sigma}_{\text{Br}}(\tilde{E}C_2, \mathbb{Z}/2). \]
For $i \leq 0$ we set $B_i = 0$. There are canonical $\mathcal{M}_2^{C^2}$-module quotients $B_{i+1} \rightarrow B_i$. Moreover, there are also $\mathcal{M}_2^{C^2}$-module inclusions
\[ B_i \hookrightarrow B_{i+1} \quad (1.4) \]
defined by the assignment $\frac{a^m}{u^n} \mapsto \frac{a^m}{u^n}$. Composing the inclusion $B_i \hookrightarrow \Sigma^2 \mathbb{Z}/2[a^{\pm 1}, u^{-1}]$ with (1.2), yields the $\mathcal{M}_2^{C^2}$-module map
\[ B_i \rightarrow \mathcal{M}_2^{C^2}. \]
Lastly we note that there are \( \mathbb{M}^C_2 \)-module maps

\[
\cdot u^2 : B_{i+1} \rightarrow B_i,
\]

defined by composing the quotient map with multiplication by \( u^2 \),

\[
\Sigma^{2-2\sigma}\mathbb{Z}/2[u^{-1}, a^{\pm 1}]/u^{-2i+2} \xrightarrow{u^2} \Sigma^{2-2\sigma}\mathbb{Z}/2[u^{-1}, a^{\pm 1}]/u^{-2i}.
\]

Explicitly it is the map

\[
\frac{\theta}{u^n} a^m \mapsto \begin{cases} 
\frac{\theta}{u^{n-2}} a^m & n \geq 2 \\
0 & \text{else.}
\end{cases}
\]

### 1.2 Our computation

We describe the main computations. Bredon motivic cohomology is graded by a 4-tuple of integers, written as \((a+p\sigma, b+q\sigma)\); this 4-tuple is viewed as a pair of \( C_2 \)-representations (here \( \sigma \) denotes the sign representation), the first one is the cohomological degree and the second representation is the weight. The grading by 4-tuples presents an organizational problem. Our solution is to organize Bredon motivic cohomology into \( \mathbb{M}^C_2 \)-modules, which we now explain. If \( X \) is a complex variety with \( C_2 \)-action, Betti realization induces a comparison homomorphism

\[
\text{Re} : H^*_{\text{Hr}}(X, \mathbb{Z}/2) \rightarrow H^*_{C_2}(X(C), \mathbb{Z}/2)
\]

between Bredon motivic cohomology of \( X \) and the Bredon cohomology of the \( C_2 \)-topological space \( X(C) \). When \( X = \text{Spec}(C) \), this induces an isomorphism of bigraded rings by Proposition 2.6,

\[
H^*_{C_2}(C, \mathbb{Z}/2) \xrightarrow{\cong} \mathbb{M}^C_2.
\]

In particular, we can view \( H^*_{C_2}(X, \mathbb{Z}/2) \) as an \( \mathbb{M}^C_2 \)-module, for each \( b, q \).

The free motivic \( C_2 \)-space \( \mathbf{EC}_2 \) can be modeled as \( \mathbb{A}(\infty \sigma) \setminus 0 \), where \( \mathbb{A}(n\sigma) \) is the \( n \)-dimensional sign representation. There is a motivic isotropy separation sequence \( \mathbf{EC}_2 \rightarrow S^0 \rightarrow \tilde{\mathbf{EC}}_2 \), where \( \tilde{\mathbf{EC}}_2 \) is defined so that this a cofiber sequence (see Section 2.1 for details), which breaks the problem of computing \( H^*_C(C, \mathbb{Z}/2) \) into pieces.

Each of \( \mathbf{EC}_2 \) and \( \tilde{\mathbf{EC}}_2 \) determine a region of \( H^*_{C_2}(C, \mathbb{Z}/2) \) and Betti realization determines the remaining nonzero region, see Theorem 4.1. These regions are shown in Figure 3. In this picture we have projected onto the plane determined by the weight. In particular, the displayed elements do not all live the same cohomological degree.
We keep track of weights via the elements $\zeta$, we leverage Voevodsky’s computation, where we find there is an isomorphism of $\mathbf{E}C_2$, we determine the Theorem 4.7

Figure 3: Regions of $H^*_{\mathbf{E}C_2}(\mathbf{C}, \mathbb{Z}/2)$ determined by $\mathbf{E}C_2$, Betti realization, and $\tilde{\mathbf{E}}C_2$. The degrees of the displayed elements are $|\xi| = (-2 + 2\sigma, -1 + \sigma)$, $|\mu| = (0, 1 - \sigma)$, $|\tau| = (0, \sigma)$.

In integer bidegrees, the Bredon motivic cohomology of $\mathbf{E}C_2$ agrees with ordinary motivic cohomology of $\mathbf{E}C_2/\mathbb{C} = B\mathbb{C}$. The motivic cohomology of $B\mathbb{C}$ was computed by Voevodsky \cite[Theorem 6.10]{voevodsky}. In our case, where the base field is $\mathbb{C}$, his computation takes the form

$$H^* \mathbf{E}C_2(\mathbb{Z}/2) \cong \mathbb{Z}/2[\tau][e_1, e_2]/(e_1^2 = e_2\tau), \quad (1.7)$$

where $|e_1| = (1, 1)$, $|e_2| = (2, 1)$, and $|\tau| = (0, 1)$. In Section 3, we leverage Voevodsky’s computation, Betti realization, and that the cohomology of $\mathbf{E}C_2$ is $(-2 + 2\sigma, -1 + \sigma)$-periodic, to find an equivariant lift of $\tau$ to an element $\tau_\sigma \in H^0_{\mathbf{E}C_2}(\mathbf{E}C_2)$ such that multiplication by $\tau_\sigma$ is an isomorphism whenever $b + q \geq 0$. Thus we find that

$$H^* \mathbf{E}C_2(\mathbb{E}C_2, \mathbb{Z}/2) \cong M_{\mathbb{Z}/2}[\xi^{\pm 1}, \tau_\sigma],$$

where $|\xi| = (-2 + 2\sigma, -1 + \sigma)$.

The cohomology of $\tilde{\mathbf{E}}C_2$ is both $(\sigma, 0)$ and $(0, \sigma)$-periodic and Betti realization identifies $\tilde{H}^* \mathbf{E}C_2(\tilde{\mathbf{E}}C_2)$ with the sub-$M_{\mathbb{Z}/2}$-module of $H^*_{\mathbf{E}C_2}(\tilde{\mathbf{E}}C_2)$

$$\tilde{H}^* \mathbf{E}C_2(\mathbb{E}C_2, \mathbb{Z}/2) \cong B_b,$$

where $B_b = \Sigma^{2 - 2\sigma}\mathbb{Z}/2[x^\pm 1, u^{-1}]/(u^{-2b})$ (if $b \geq 1$, it is 0 otherwise) is the $M_{\mathbb{Z}/2}$-module introduced in Remark 1.3. We keep track of weights via the elements $\tau_\sigma$ and $\mu$, where $|\tau_\sigma| = (0, \sigma)$ and $|\mu| = (0, 1 - \sigma)$, so that

$$\tilde{H}^* \mathbf{E}C_2(\mathbb{Z}/2) \cong \bigoplus_{i \geq 1, j \in \mathbb{Z}} B_i \left\{ \mu^i \tau_\sigma^j \right\}.$$

Having determined the $M_{\mathbb{Z}/2}$-module structures in all of the regions in Figure 3, we determine the multiplicative structure in Theorem 4.7, where we find there is an isomorphism of $M_{\mathbb{Z}/2}$-algebras

$$H^* \mathbf{E}C_2(\mathbb{C}, \mathbb{Z}/2) \cong M_{\mathbb{Z}/2}[\xi, \tau_\sigma, \mu]/(\xi \mu - u^2) \oplus \left( \bigoplus_{i \geq 1} B_i \left\{ \mu^i \right\} \right), \quad (1.8)$$
The left hand summand comes from the regions determined by $\mathbb{E}C_2$ and Betti realization in Figure 3. The right hand summand arises from the region determined by $\mathbb{E}C_2$. The multiplicative structure involving elements in this region is determined as follows.

(i) $\cdot : B_i \left\{ \frac{n^i}{\tau^i} \right\} \to B_{i+1} \left\{ \frac{n^{i+1}}{\tau^{i+1}} \right\}$ is the inclusion (1.4).

(ii) $\cdot : B_i \left\{ \frac{n^i}{\tau^i} \right\} \to B_{i-1} \left\{ \frac{n^{i-1}}{\tau^{i-1}} \right\}$ is (1.6), multiplication by $u^2$.

(iii) $\cdot \tau : B_i \left\{ \frac{n^i}{\tau^i} \right\} \to B_i \left\{ \frac{n^i}{\tau^i} \right\}$ is the identity if $j \geq 2$.

(iv) $\cdot$ a $\tau$-multiplication starting in weights $i-(i+1)\sigma$, is the map $\cdot \tau : B_i \left\{ \frac{n^i}{\tau^i} \right\} \to \mathbb{M}_2^{C_2} \{ \mu^i \}$ determined by (1.5). These are exactly the multiplications crossing the border from the region determined by $\mathbb{E}C_2$ into the region determined by Betti realization, see Figure 3.

(v) All products in the right hand summand are trivial.

Outline. A brief outline of the paper is as follows. Sections 1 and 2 are devoted to the introduction and preliminaries. The main computations of Bredon motivic cohomology are carried out in Sections 3 and 4. In the last section, we generalize the results to any algebraically closed field of characteristic zero via a rigidity result for Bredon motivic cohomology.

Notation.

- $H^{a+p\sigma,b+q\sigma}_C(X, \underline{A})$ is the Bredon motivic cohomology of a $C_2$-smooth scheme, with coefficients $\underline{A}$.
- $H^{a,q}_C(X, A)$ is motivic cohomology of a smooth scheme $X$.
- $H^{a,b}_B(X, \underline{A})$ is the Bredon cohomology of a $C_2$-topological space $X$ with coefficients in the constant Mackey functor $\underline{A}$.
- We write $\star$ for a RO($C_2$)-grading and $\star$ for a $\mathbb{Z}$-grading.

For example, $H^*_{C_2}(X) = \oplus_{a,b,p,q} H^{a+p\sigma,b+q\sigma}_C(X)$ and $H^{*,*}(X) = \oplus_{a,b} H^{a,b}_C(X)$.

- $S^\sigma$ is the topological sphere associated to the real sign representation $\sigma$.
- All $C_2$-varieties are over $\mathbb{C}$ and we view $C_2$ as a group scheme by $C_2 = \text{Spec}(\mathbb{C}) \sqcup \text{Spec}(\mathbb{C})$.
- $\mathbb{M}_2^{C_2} := H^*_B(\text{pt}, \mathbb{Z}/n)$.

Acknowledgements. The authors wish to thank Institut Mittag-Leffler, Stockholm, where the research of this paper started in 2017 during the program on Algebra-Geometric and Homotopical Methods. Heller and Østvær thank the Isaac Newton Institute for Mathematical Sciences for support and hospitality during the program on K-theory, algebraic cycles and motivic homotopy theory in 2020. We are grateful to the referee for useful comments on a previous draft of this paper.

2 Preliminaries

We record some background on Bredon motivic cohomology.

2.1 Equivariant motivic homotopy

The stable equivariant motivic homotopy category $\text{SH}^{C_2}(k)$ is the stabilization of Voevodsky’s category of equivariant motivic spaces $\text{SH}$, with respect to Thom spaces of representations. We recall a few key facts and the notation we use in the case $G = C_2$. See [9], [8], or [4] for details.

Let $V = a + p\sigma$ be a $C_2$-representation, where $a$ denotes the $a$-dimensional trivial representation and $p\sigma$ is the $p$-dimensional sign representation. We write $A(V)$ and $P(V)$ for the $C_2$-schemes $A^\dim(V)$ and $P^\dim(V)-1$ equipped with the corresponding action coming from $V$. The associated motivic representation sphere is

$$T^V := P(V \oplus 1)/P(V).$$

Indexing is based on the following four spheres. There are two topological spheres $S^1$, $S^\sigma$ and two algebra-geometric spheres $S_t = (\mathbb{A}^1 \setminus \{0\}, 1)$ equipped with trivial action, and $S_t^\sigma = (\mathbb{A}^1 \setminus \{0\}, 1)$ equipped the $C_2$-action $x \mapsto x^{-1}$. We write

$$S^{a+p\sigma,b+q\sigma} := S^{a-b} \wedge S^{(p-q)\sigma} \wedge S^b \wedge S^q.$$

In this indexing, we have $T \cong S^{2,1}$ and $T^\sigma \cong S^{2n,\sigma}$. The stable equivariant motivic homotopy category $\text{SH}^{C_2}(k)$ is the stabilization of (based) $C_2$-motivic spaces with respect to the motivic sphere $T^\rho$ corresponding to the regular representation $\rho = 1 + \sigma$.

We make use of two fundamental cofiber sequences in $\text{SH}^{C_2}(k)$. The first is

$$C_{2^1} \to S^0 \to S^\sigma. \quad (2.1)$$

The second is

$$\mathbb{E}C_{2^1} \to S^0 \to \tilde{\mathbb{E}}C_2. \quad (2.2)$$

Here, $\mathbb{E}C_2$ is the universal free motivic $C_2$-space. It has a geometric model, $\mathbb{E}C_2 \simeq \text{colim}_n A(n\sigma) \setminus \{0\}$, see [4, Section 3]. The quotient $\mathbb{E}C_2/C_2 \simeq \text{colim}_n (A(n\sigma) \setminus \{0\})/C_2$ is the geometric classifying space $\mathbb{B}C_2$ constructed by Morel-Voevodsky [12] and Totaro [14]. Note also that $\tilde{\mathbb{E}}C_2 = \text{colim}_n S^{2n\sigma,n\sigma}$. In particular, the maps $S^0 \to T^\sigma$ and $S^0 \to S^\sigma$ induce equivalences

$$\tilde{\mathbb{E}}C_2 \simeq T^\sigma \wedge \tilde{\mathbb{E}}C_2 \quad \text{and} \quad \tilde{\mathbb{E}}C_2 \simeq S^\sigma \wedge \tilde{\mathbb{E}}C_2,$$

see [8, Proposition 2.9].

Equipping a variety with trivial action $\text{Sm}_k \to \text{Sm}^{C_2}_k$ induces a functor $\text{SH}(k) \to \text{SH}^{C_2}(k)$.

### 2.2 Bredon motivic cohomology

Bredon motivic cohomology is represented in $\text{SH}^{C_2}(k)$ by the spectrum $M\mathbb{A}$ associated to an abelian group $A$, where $M\mathbb{A}_C = A_{tr,C_2}(T^\nu_\mathbb{P})$ is the free presheaf with equivariant transfers, see [8] for details.

**Definition 2.3** ([8]). The Bredon motivic cohomology of a motivic $C_2$-spectrum $E$ with coefficients in an abelian group $A$ is defined by

$$\widetilde{H}^{a+\rho,b+q\sigma}_{C_2}(E,A) = [E, S^{a+\rho,b+q\sigma} \wedge M\mathbb{A}]_{\text{SH}^{C_2}(k)}.$$

If $X \in \text{Sm}^{C_2}_k$ we typically write

$$H^{a+\rho,b+q\sigma}_{C_2}(X,A) := \widetilde{H}^{a+\rho,b+q\sigma}_{C_2}(X_+,A).$$

When $A$ is a ring, then $H^{C_2}_{-\mathbb{A}}(X,A)$ is a graded commutative ring by [8, Proposition 3.24]. Specifically this means that if $x \in H^{a+\rho,b+q\sigma}_{C_2}(X,A)$ and $y \in H^{c+\sigma,d+t\sigma}_{C_2}(X,A)$, then

$$x \cup y = (-1)^{ac+pa} y \cup x.$$

A few features of this theory, which we use are the following (see [8]).

- If $E$ is in the image of $\text{SH}(k) \to \text{SH}^{C_2}(k)$, i.e. it has “trivial action”, then there is an isomorphism in integral bidegrees with ordinary motivic cohomology,

$$\widetilde{H}^{a,b}_{C_2}(E,A) \cong \widetilde{H}^{a,b}(E,A).$$

- If $X$ has free action, then there is an isomorphism in integral bidegrees with ordinary motivic cohomology,

$$H^{a,b}_{C_2}(X,A) \cong H^{a,b}(X/C_2,A).$$

- $H^{a,\cdot}_{C_2}(\mathbb{E}C_2,A)$ is $(-2 + 2\sigma, -1 + \sigma)$-periodic.

### 2.3 Betti realization

The map of sites $\text{Sm}^{C_2}_k \to \text{Top}^{C_2}$, given by $X \to X(\mathbb{C})$, where the set of complex points is equipped with the analytic topology, extends to a functor $\text{Re} : \text{SH}^{C_2}(\mathbb{C}) \to \text{SH}^{C_2}$ between the stable equivariant motivic homotopy category over $\mathbb{C}$ and the classical stable equivariant homotopy category. We refer to this functor as the Betti realization.
The indexing of the spheres above was chosen to interact well with complex Betti realization; we have \( \text{Re}(S^{2p+1},b+q,a) \simeq S^{a+p} \).

By [8, Theorem A.29], \( \text{Re}(M_A) \simeq H_A \), where \( H_A \) is the equivariant Eilenberg-MacLane spectrum associated to the constant Mackey functor \( A \). In particular, for any smooth \( C_2 \)-scheme over \( C \) there is a map

\[
\text{Re} : H_{C_2}^{a+p},b+q (X, \Delta) \to H_{Br}^{a+p},b+q (X(C), \Delta).
\]

Betti realization takes the cofiber sequences (2.1) and (2.2) to the corresponding ones in \( \text{SH}^{C_2} \). Given \( X \) in \( \text{SH}^{C_2}(C) \), we obtain a comparison of long exact sequences

\[
\begin{align*}
\cdots & \to \tilde{H}_{C_2}^{a+(p-1)\sigma},b+q (X, \Delta) \to \tilde{H}_{C_2}^{a+p},b+q (X, \Delta) \to \tilde{H}_{a+p},b+q (X, A) \to \cdots \\
\downarrow & \quad \downarrow \\
\cdots & \to \tilde{H}_{Br}^{a+(p-1)\sigma} (\text{Re}(X), \Delta) \to \tilde{H}_{Br}^{a+p} (\text{Re}(X), \Delta) \to \tilde{H}_{Br}^{a+p} (\text{Re}(X), A) \to \cdots
\end{align*}
\]  

(2.4)

as follows. The top row of this sequence is obtained by smashing \( X \) with (2.1) and the bottom is obtained similarly via Betti realization. Here we use the identifications \( \tilde{H}_{C_2}^{a+p},b+q (C_2+ \wedge X) \cong \tilde{H}_{a+p},b+q (X) \) and \( \tilde{H}_{Br}^{a+p} (\text{Re}(X)) \cong \tilde{H}_{Br}^{a+p} (\text{Re}(X)) \) and the \( \text{Re} \) is compatible with these identifications, see [8, Proposition 3.14]. Smashing \( X \) with (2.2) we obtain the comparison of long exact sequences

\[
\begin{align*}
\cdots & \to \tilde{H}_{C_2}^{a+p},b+q (\tilde{EC}_2 \wedge X, \Delta) \to \tilde{H}_{C_2}^{a+p},b+q (X, \Delta) \to \tilde{H}_{a+p},b+q (X, A) \to \cdots \\
\downarrow & \quad \downarrow \\
\cdots & \to \tilde{H}_{Br}^{a+p} (\tilde{EC}_2 \wedge \text{Re}(X), \Delta) \to \tilde{H}_{Br}^{a+p} (\text{Re}(X), \Delta) \to \tilde{H}_{Br}^{a+p} (\text{Re}(X), A) \to \cdots
\end{align*}
\]  

(2.5)

Using the Beilinson-Lichtenbaum theorem proved by Voevodsky and Rost [15],[17], it is shown in [8] that Betti realization is an isomorphism in a suitable range, on Bredon cohomology of smooth schemes. In Section 4, we will see that a stronger result holds for \( X = \text{Spec}(C) \). For the moment, we note that in nonnegative integer weights, we always have an isomorphism for finite coefficients. In particular, Betti realization induces an isomorphism of rings \( H^*_{C_2} (C, \mathbb{Z}/n) \cong \mathcal{M}_n^C \) and so \( H^*_{C_2} (X, \mathbb{Z}/n) \) is a module over \( \mathcal{M}_n^C \). In fact, by [18] or the same argument below, Betti realization is an isomorphism in weight zero even with \( \mathbb{Z} \)-coefficients.

**Proposition 2.6.** Let \( A \) be a finite abelian group and \( b \geq 0 \). Betti realization induces an isomorphism for any \( a, p \)

\[
H^{a+p},b (C, \Delta) \xrightarrow{\cong} H_{Br}^{a+p} (\text{pt}, \Delta).
\]

**Proof.** If \( b \geq 0 \), then \( H^{a,b} (C, A) \to H^{a}_{\text{sing}} (C, A) \) is an isomorphism for all \( a \). In particular the result holds for \( p = 0 \). Using the comparison long exact sequence (2.4) and the five lemma, the result holds for all \( p \) by induction. \( \square \)

### 2.4 Vanishing of Bredon motivic cohomology

An important feature of motivic cohomology is its vanishing regions. If \( X \in \text{Sm}_k \) then \( H^{a,b} (X, \mathbb{Z}/n) = 0 \) in any of the following cases

1. \( a > 2b \),
2. \( a > b + \text{dim}(X) \),
3. \( b < 0 \).

The vanishing regions for \( H^*_{C_2} \) are more complicated. In this subsection \( k \) is a field with \( \text{char}(k) \neq 2 \).

**Proposition 2.7.**

1. \( H^*_{C_2} (\tilde{EC}_2, \mathbb{Z}/n) \cong \tilde{H}^{*} (\Sigma BC_2, \mathbb{Z}/n) \).
2. \( H_{C_2}^{a+p} (\mathbb{E}C_2, \mathbb{Z}/n) = 0 \) if \( b \leq 0 \)
To see this, we first note that $H^a(X, \mathbb{Z}/n)$ is (σ, 0) and (0, σ)-periodic, (2) follows from (1). The first statement follows from the long exact sequence induced by (2.2). Indeed, by [8, Proposition 3.16] the map $H^a_* (k, \mathbb{Z}/n) \to H^a_* (\mathcal{EC}_2, \mathbb{Z}/n)$ is isomorphic to the split monomorphism $f^* : H^a_* (k, \mathbb{Z}/n) \to H^a_* (\mathcal{BC}_2, \mathbb{Z}/n)$, where $f : \mathcal{BC}_2 \to \text{Spec}(k)$ is the projection. Thus $\tilde{H}^{a+1,*}_c (\mathcal{EC}_2, \mathbb{Z}/n)$ is isomorphic to the cokernel of $f^*$, which is $\tilde{H}^{a+1,*}_c (\Sigma \mathcal{BC}_2, \mathbb{Z}/n)$.

**Proposition 2.8.** Let $X \in \text{Sm}_k^{C_2}$ and suppose that $b + q < 0$ and $b < 0$. Then

$$H^b_{C_2} (X, \mathbb{Z}/n) = 0.$$ 

**Proof.** Since $b < 0$, we have $\tilde{H}^{a+\varphi,b+q}_c (\mathcal{EC}_2 \times X_+) = 0$. Using the cofiber sequence (2.2), we obtain

$$H^b_{C_2} (X, \mathbb{Z}/n) \cong H^a_{\mathcal{EC}_2} (X) \cong H^a_{\mathcal{EC}_2} (X).$$

Since $H^a_{\mathcal{EC}_2} (X) \cong H^a_{\mathcal{EC}_2} (X)$, it suffices to see that $H^a_{\mathcal{EC}_2} (X) = 0$ for $n < 0$. This follows from the case $p = 0$, by induction using (2.1).

**Proposition 2.9.** If $a \geq 2b + 2$ then for any $X \in \text{Sm}_k^{C_2}$,

1. $H^a_{C_2} (X \times \mathcal{EC}_2, \mathbb{Z}/n) = 0$, and
2. the projection $X \times \mathcal{EC}_2 \to X$ induces an isomorphism

$$H^a_{C_2} (X, \mathbb{Z}/n) \cong H^a_{\mathcal{EC}_2} (X \times \mathcal{EC}_2, \mathbb{Z}/n).$$

**Proof.** The two statements are equivalent using (2.2). Therefore, we will establish the first one. Since $H^a_{C_2} (X \times \mathcal{EC}_2, \mathbb{Z}/n) \cong H^a_{\mathcal{EC}_2} (X \times \mathcal{EC}_2, \mathbb{Z}/n)$, we can assume that $p = q = 0$. We can assume that $X$ has trivial action, since $H^a_{C_2} (X \times \mathcal{EC}_2, \mathbb{Z}/n) \cong H^a_{\mathcal{EC}_2} (X \times \mathcal{EC}_2, \mathbb{Z}/n)$ by [4, Proposition 4.10].

Consider the exact sequence from (2.2).

$$\cdots \to H^{a-1,b}_c (X \times \mathcal{EC}_2, \mathbb{Z}/n) \to H^{a,b}_c (X, \mathcal{EC}_2, \mathbb{Z}/n) \to H^{a,b}_c (X \times \mathcal{EC}_2, \mathbb{Z}/n) \to H^{a,b}_c (X \times \mathcal{EC}_2, \mathbb{Z}/n).$$

Now $H^{a,b}_c (X \times \mathcal{EC}_2, \mathbb{Z}/n) \cong H^{a,b}_c (X \times \mathcal{EC}_2, \mathbb{Z}/n)$, and if $a > 2b$ this last group is zero and so the proposition follows.

**Proposition 2.10.** For any $X \in \text{Sm}_k^{C_2}$, if $a \geq 2b + 2$ and $p \geq 2q$ then we have that

$$H^a_{C_2} (X, \mathbb{Z}/n) = 0.$$ 

**Proof.** By Proposition 2.9, it suffices to show that $H^a_{C_2} (X \times \mathcal{EC}_2, \mathbb{Z}/n) = 0$. By [8, Theorem 5.4],

$$H^a_{C_2} (X \times \mathcal{EC}_2) \cong H^{a+2b+2q}_c (X \times \mathcal{EC}_2).$$

If $p = 2q$, then $H^{a+2b+2q}_c (X \times \mathcal{EC}_2) \cong H^{a+2q}_c (X \times \mathcal{EC}_2)$. This group vanishes when $a > 2b$. To conclude the proposition, we use the long exact sequence obtained from (2.1) and induction on $p \geq 2q$.

The following example shows that the general vanishing range in the previous proposition can’t be improved.

**Example 2.11.** For any $p$, we have

$$H^{2+2n-2q}_{C_2} (P^{1*}, \mathbb{Z}/n) \neq 0.$$ 

to see this, we first note that $H^{2+2n-2q}_{C_2} (P^{1*}, \mathbb{Z}/n) = 0$ (see the proof of Proposition 3.3) and therefore from (2.2) we see that $H^{2+2n-2q}_{C_2} (P^{1*}, \mathbb{Z}/n) \cong H^{2+2n-2q}_{C_2} (P^{1*}, \mathbb{Z}/n)$. Since $P^{1*} \cong T \vee S^0$, we thus have

$$H^{2+2n-2q}_{C_2} (P^{1*}, \mathbb{Z}/n) \cong H^{2+2n-2q}_{C_2} (P^{1*}, \mathbb{Z}/n) \cong H^{2+2n-2q}_{C_2} (P^{1*}, \mathbb{Z}/n) \cong H^{2+2n-2q}_{C_2} (P^{1*}, \mathbb{Z}/n).$$

This group is nonzero since $H^{2+2n-2q}_{C_2} (P^{1*}, \mathbb{Z}/n) \cong \tilde{H}^{2+2n-2q}_{C_2} (P^{1*}, \mathbb{Z}/n)$.
3 Bredon motivic cohomology of $\text{EC}_2$

In this section, we compute the Bredon motivic cohomology ring of $\text{EC}_2$. Betti realization plays a key role in our determination of this ring and we start by leveraging motivic cohomology of $\mathcal{B}\text{C}_2$. From [8, Proposition 3.16], we have an isomorphism $H^a_{\mathcal{C}_2}(\text{EC}_2, A) \cong H^{a,b}(\mathcal{B}\text{C}_2, A)$ and this isomorphism fits into the commutative diagram.

$$
\begin{array}{ccc}
H^a_{\mathcal{C}_2}(\text{EC}_2, A) & \rightarrow & H^a(\mathcal{B}\text{C}_2, A) \\
\downarrow \text{Re} & & \downarrow \text{Re} \\
H^a_{\text{Br}}(\text{EC}_2, A) & \cong & H^a_{\text{sing}}(\mathcal{B}\text{C}_2, A).
\end{array}
$$

**Lemma 3.1.** Let $A$ be a finite abelian group. Betti realization

$$
\text{Re} : H^{a,b}(\mathcal{B}\text{C}_2, A) \rightarrow H^a_{\text{sing}}(\mathcal{B}\text{C}_2, A)
$$

is an isomorphism if $a \leq 2b$.

**Proof.** If $A = \mathbb{Z}/2$, this can be read off of Voevodsky’s computation (1.7), since Betti realization of $e_1$ is the generator of $H^1_{\text{sing}}(\mathcal{B}\text{C}_2, \mathbb{Z}/2)$. In general, we use that $\mathcal{B}\text{C}_2$ sits in the cofiber sequence, see [16, Section 6],

$$
\mathcal{B}\text{C}_2 \rightarrow \mathbb{P}^\infty_+ \rightarrow \text{Th}(O(-2)).
$$

The lemma follows from the comparison of long exact sequences induced by this cofiber sequence, the five lemma, the Thom isomorphism, and that $\text{Re} : H^{a,b}(\mathbb{P}^\infty_+; A) \rightarrow H^a_{\text{sing}}(\mathbb{P}^\infty_+, A)$ is an isomorphism if $a \leq 2b$. \hfill \square

**Proposition 3.2.** Suppose $b + q \geq 0$. Then

$$
H^{a+p+q}_C(\text{EC}_2, \mathbb{Z}/n) \cong \begin{cases} 
H^{a+p}\text{Br}(\text{EC}_2, \mathbb{Z}/n) & a \leq 2b \\
0 & a = 2b + 1 \\
H^{a+2q(p-2q)}\text{Br}(\text{EC}_2, \mathbb{Z}/n) & a \geq 2b + 2.
\end{cases}
$$

Furthermore, Betti realization is an isomorphism if $a \leq 2b$. It is multiplication by 2 if $a \geq 2b + 2$, $p = -a$, and $a$ is even. All other Betti realizations are zero.

**Proof.** Since $H^{a+p}_C(\text{EC}_2, \mathbb{Z}/n)$ is $(-2 + 2\sigma, -1 + \sigma)$ periodic by [8, Theorem 5.4] and the statement of the proposition is compatible with this periodicity, it suffices to treat the case $q = 0$. We now assume that $q = 0$.

When $p = 0$, then $H^{a,b}_C(\text{EC}_2, \mathbb{Z}/n) \cong H^{a,b}(\mathcal{B}\text{C}_2, \mathbb{Z}/n) = 0$ if $a > 2b$ and by Lemma 3.1, Betti realization is an isomorphism $a \leq 2b$.

We suppress the coefficient group for typographical simplicity and proceed by induction on $p$. To begin with, we use the comparison of exact sequences (2.4)

$$
\cdots \rightarrow H^{i+p,b}(C) \rightarrow H^{i+p}\text{Br}(\text{EC}_2) \rightarrow H^{i+p+1,\sigma,b}(\text{EC}_2) \rightarrow H^{i+1+p,b}(C) \rightarrow \cdots
$$

$$
\cdots \rightarrow H^{i+p}\text{Br}(\text{EC}_2) \rightarrow H^{i+\sigma,p}\text{Br}(\text{EC}_2) \rightarrow H^{i+1,\sigma}\text{Br}(\text{EC}_2) \rightarrow H^{i+1+p}\text{Br}(\text{EC}_2) \rightarrow \cdots
$$

A straightforward induction shows that for $p \geq 0$, Betti realization $H^{i+p}\text{Br}(\text{EC}_2) \rightarrow H^{i+\sigma,p}\text{Br}(\text{EC}_2)$ is an isomorphism if $i \leq 2b$ and $H^{i+p,\sigma,p}\text{Br}(\text{EC}_2) = 0$ if $i > 2b$. This establishes the result in case $p \geq 0$.

Now we establish the result for $p \leq 0$. Using the comparison of exact sequences (2.4) and the five lemma, we find that if the map $H^{i+p,\sigma}\text{Br}(\text{EC}_2) \rightarrow H^{i+\sigma,p}\text{Br}(\text{EC}_2)$ is an isomorphism for all $i \leq 2b$ when $n = p + 1$, then this map is also an isomorphism for all $i \leq 2b$ when $n = p$. By downward induction on $p$, starting with $p = 0$, we deduce the computation for $a \leq 2b$. 
Now assume that $H^{2b+1+n\sigma,b}(EC_2) = 0$ for $n = p+1$. If $p \geq -(2b+1)$, if follows from the exact sequence induced by (2.1) that this group vanishes for $n = p$ as well. Thus downward induction implies the result for $p < -(2b+1)$ once we treat the case $p = -(2b+1)$. Consider the comparison of exact sequences

$$
\begin{align*}
H^{2b-2\sigma}_{C_2}(EC_2) & \xrightarrow{\delta} H^{0,b}(C) \xrightarrow{\cong} H^{2b+1-(2b+1)\sigma,b}_{C_2}(EC_2) \rightarrow H^{2b+1-2\sigma,b}_{C_2}(EC_2) = 0 \\
H^{2b-2\sigma}_{Br}(EC_2) & \xrightarrow{\cong} H^{0}_{sing}(pt) \xrightarrow{\cong} H^{2b+1-(2b+1)\sigma}_{Br}(EC_2) \rightarrow H^{2b+1-2\sigma,b}_{Br}(EC_2).
\end{align*}
$$

That the bottom left horizontal arrow is an isomorphism can be seen by noting that this map can be identified with the restriction to the fiber homomorphism $H^{2b}_{sing}((\Th(\gamma), Z/n)) \rightarrow H^{2b}_{sing}(S^{2b}, Z/n)$, where $\gamma$ is the vector bundle on $BC_2$ determined by the $b$-dimensional complex sign representation. This map is an isomorphism because $\gamma$ is orientable. It follows that the map labeled $\phi$ is an isomorphism and so $H^{2b+1-(2b+1)\sigma,b}_{C_2}(EC_2) = 0$.

If $a \geq 2b+2$, then $H^{a+\sigma,b}_{C_2}(EC_2) \cong H^{a+\sigma,b}_{Br}(\tilde{EC}_2)$, since $H^{a+\sigma,b}(EC_2) \cong \tilde{H}^{a,b}(\Sigma BC_2) = 0$ for $a \geq 2b+2$. The case $a \geq 2b+2$ thus follows from Proposition 2.6.

For the last statement about Betti realization, we have already checked that it is an isomorphism if $a \leq 2b$. The remaining part of the statement follows from the commutative diagram, where $2b+2 \leq a$

$$
\begin{align*}
H^{a+\sigma,b}_{C_2}(C) & \xrightarrow{\cong} H^{a+\sigma,b}_{Br}(EC_2) \\
H^{a+\sigma}_{Br}(pt) & \xrightarrow{2} H^{a+\sigma}_{Br}(EC_2).
\end{align*}
$$

To see that the bottom arrow is multiplication by 2, note that for $2 \leq a$, $H^{a+\sigma}_{Br}(pt, Z) \cong H^{1-a-\sigma}_{Br}(EC_2, Z)$, see e.g., [5] for details, and under this identification the lower arrow is induced by the norm map $HZ_{hC_2} \rightarrow HZ_{hC_2}$.

\[ \square \]

Proposition 3.3. If $b + q < 0$ then $H^{*+b+q\sigma}_{C_2}(EC_2, Z/n) = 0$.

Proof. We have that $H^{*+b+q\sigma}_{C_2}(EC_2, Z/n) \cong H^{*+2q+(p-2q)\sigma}_{C_2}(EC_2, Z/n)$.

Using the vanishing $H^{*+2q+b\sigma}_{C_2}(EC_2, Z/n) \cong H^{*+2q+b\sigma}_{Br}(EC_2, Z/n) = 0$ together with the exact sequence induced by (2.1), the result follows by induction.

\[ \square \]

Notation 3.4. We introduce certain elements in the cohomology of Spec$(C)$ and $EC_2$. The stated isomorphisms between the cohomology of Spec$(C)$ and $EC_2$ all follow from the exact sequences associated to (2.2) together with the vanishing of the Bredon motivic cohomology of $\tilde{EC}_2$ in the relevant degrees, see Proposition 2.7.

- $\tau_\sigma \in H^{\sigma}_{C_2}(C, Z/n) \cong H^{\sigma}_{C_2}(EC_2, Z/n) \cong Z/n$ is a generator.
- $\xi \in H^{2+2\sigma,-1+\sigma}_{C_2}(C, Z/n) \cong H^{2+2\sigma,-1+\sigma}_{C_2}(EC_2, Z/n) \cong Z/n$ is a generator.

Next we compute the multiplicative structure. The $M^{C_2}_{n}$-modules $H^{*+b+q\sigma}_{C_2}(EC_2, Z/n)$ together with multiplicative structure are displayed in Figure 4 below.

Lemma 3.5. Let $b + q \geq 0$. Then

$$
\tau_\sigma : H^{*+\sigma,b+q\sigma}_{C_2}(EC_2, Z/n) \xrightarrow{\cong} H^{*+\sigma,b+(q+1)\sigma}_{C_2}(EC_2, Z/n)
$$

is an isomorphism.

Proof. By periodicity, it suffices to treat the case $q = 0$.

If $a \leq 2b$, the claim follows from Proposition 3.2, since $\Re(\tau_\sigma) = 1$. It holds for $a = 2b + 1$ as these groups are both zero. If $a \geq 2b+2$, then $\tilde{H}^{a+\sigma,b+q\sigma}_{C_2}(EC_2, Z/n) = 0$ by Proposition 2.7 which implies
that $H_{C_2}^{a+p\sigma,b+q\sigma}(C,\mathbb{Z}/n) \cong H_{C_2}^{a+p\sigma,b+q\sigma}(EC_2,\mathbb{Z}/n)$. Multiplication by $\tau_\sigma$ fits into the commutative triangle

$$
\begin{array}{ccc}
H_{C_2}^{a+p\sigma,b}(C,\mathbb{Z}/n) & \xrightarrow{\tau_\sigma} & H_{C_2}^{a+p\sigma,b+\sigma}(C,\mathbb{Z}/n) \\
\downarrow & & \\
H_{Br}^{a+p\sigma}(pt,\mathbb{Z}/n).
\end{array}
$$

It follows that $\cdot\tau_\sigma : H_{C_2}^{a+p\sigma,b}(EC_2,\mathbb{Z}/n) \to H_{C_2}^{a+p\sigma,b+\sigma}(EC_2,\mathbb{Z}/n)$ is injective. But it follows from Proposition 3.2 that either both of these groups are $\mathbb{Z}/n$ or both are 0. Thus the map is an isomorphism.

**Theorem 3.6.** Let $n \geq 2$. The canonical map is an isomorphism of rings

$$
\mathbb{M}^C_n[\xi^\pm, \tau_\sigma] \cong H_{C_2}^{*,*}(EC_2,\mathbb{Z}/n).
$$

**Proof.** Since $H_{C_2}^{*,0}(\tilde{EC}_2,\mathbb{Z}/n) = 0$, we have $H_{C_2}^{*,0}(C,\mathbb{Z}/n) \cong H_{C_2}^{*,0}(EC_2,\mathbb{Z}/n)$. Thus, together with periodicity, we have an isomorphism

$$
H_{C_2}^{*,0}(C,\mathbb{Z}/n)[\xi^\pm] \cong \bigoplus_{a,p,b} H_{C_2}^{a+p\sigma,b}(EC_2,\mathbb{Z}/n).
$$

The result now follows from Lemma 3.5.

**Remark 3.7.** Recall (1.7) that $H_{C_2}^{*,*}(EC_2,\mathbb{Z}/2) \cong H^{*,*}(BC_2,\mathbb{Z}/2) \cong \mathbb{Z}/2[[e_1,e_2]/\{e_1^2 = e_2\tau\}]$, where $|e_1| = (1,1)$ and $|e_2| = (2,1)$. In terms of the generators that appear in Theorem 3.6 we have $e_1 = \frac{u_2\tau}{\xi}, e_2 = \frac{u_2}{\xi}, \tau = \frac{u_2}{\xi}$.

The multiplicative structure of $H_{C_2}^{*,*}(EC_2)$ is displayed the following figure.

![Figure 4: $H_{C_2}^{*,b+q\sigma}(EC_2,\mathbb{Z}/n)$, the elements have degrees $|\xi| = (-2+2\sigma,-1+\sigma)$ and $|\tau_\sigma| = (0,\sigma)$. Vertical green lines are multiplication by $\tau_\sigma$, upward diagonal red lines indicate multiplication by $\xi$ and downward diagonal red lines indicate multiplication by $\xi^{-1}$.](image-url)
We end this section with a determination of $H^*_{C_2}(\tilde{E}C_2, \mathbb{Z}/2)$. The $\mathbb{M}^2_{C_2}$-submodules of $\tilde{H}^*_{Br}(\tilde{E}C_2, \mathbb{Z}/2)$, defined by $B_i := \Sigma^2-2\sigma\mathbb{Z}/2[a^{\pm 1}, u^{-1}]/(u-2^i)$ were introduced in Remark 1.3. In the following proposition $\mu$ and $\tau_\sigma$ are formal variables which serve the purpose of placing $B_i$ into the correct weight. The names of these formal variables are chosen to indicate the $H^*_{C_2}(C, \mathbb{Z}/2)$-module structure, which will be determined in the next section.

**Proposition 3.8.** There is an isomorphism of $\mathbb{M}^2_{C_2}$-modules

\[ \tilde{H}^{*,*}(\tilde{E}C_2, \mathbb{Z}/2) \cong \bigoplus_{i \geq 1, j \in \mathbb{Z}} B_i \{ \mu^i \tau_\sigma^j \}. \]

where $|\tau_\sigma| = (0, \sigma)$ and $|\mu| = (0, 1 - \sigma)$.

**Proof.** It follows from Proposition 2.7 and Lemma 3.1 that Betti realization

\[ \text{Re} : \tilde{H}^{a+p\sigma,b+qa}_{C_2}(\tilde{E}C_2, \mathbb{Z}/2) \to \tilde{H}^{a+p\sigma}_{Br}(\tilde{E}C_2, \mathbb{Z}/2) \]

is an isomorphism if $b \geq 0$ and $a \leq 2b + 1$ and $\tilde{H}^{a+p\sigma,b+qa}_{C_2}(\tilde{E}C_2, \mathbb{Z}/2) = 0$ if $b \leq 0$ or $a > 2b + 1$. In particular we see that for $b \geq 1$ Betti realization identifies $\tilde{H}^{*,b+qa}_{C_2}(\tilde{E}C_2)$ with the submodule

\[ \bigoplus_{i \leq 2b+1} \tilde{H}^{i+\sigma}_{C_2}(\tilde{E}C_2) \subseteq \tilde{H}^{*,b}_{Br}(\tilde{E}C_2). \]

This is precisely the submodule $B_b = \Sigma^2-2\sigma\mathbb{Z}/2[u^{-1}, a^{\pm 1}]/u-2^b$, see Remark 1.3.

We equip \( \bigoplus_{i \geq 1, j \in \mathbb{Z}} B_i \{ \mu^i \tau_\sigma^j \} \) with a $\mathbb{M}^2_{C_2}[\xi, \tau_\sigma, \mu]/(\xi \mu - u^2)$-module structure as follows,

- $\cdot_{\tau_\sigma} : B_i \{ \mu^i \tau_\sigma^j \} \to B_i \{ \mu^i \tau_\sigma^{j+1} \}$ is the identity.
- $\cdot : B_i \{ \mu^i \tau_\sigma^j \} \to B_{i+1} \{ \mu^{i+1} \tau_\sigma^j \}$ is the inclusion (1.4).
- $\cdot : B_i \{ \mu^i \tau_\sigma^j \} \to B_{i-1} \{ \mu^{i-1} \tau_\sigma^j \}$, for $i \geq 2$, is (1.6), multiplication by $u^2$.

We'll see in the next section that this describes the action of $H^*_{C_2}(C)$. The cohomology of $\tilde{E}C_2$, together with the module structure just described, is displayed in the following figure.

![Figure 5: $\tilde{H}^{*,b+q\sigma}_{C_2}(\tilde{E}C_2, \mathbb{Z}/2)$](image-url)

Vertical green lines are multiplication by $\tau_\sigma$, diagonal blue lines are multiplication by $\mu$. The curved red lines indicate the action of $\xi$, which acts as multiplication by $u^2$. 

\[ i = \Sigma^2-2\sigma\mathbb{Z}/2[u^{-1}, a^{\pm 1}]/u-2^i \]
4 Bredon motivic cohomology of $C$

This section identifies the Bredon motivic cohomology ring of the complex numbers with $\mathbb{Z}/2$ coefficients.

We begin with some additive structure.

**Theorem 4.1.** Let $n \geq 2$ be a natural number.

1. If $b \geq 0$ and $b + q \geq 0$ then Betti realization induces an isomorphism

$$\text{Re} : H^{*,b+q}_{C_2}(C, \mathbb{Z}/n) \xrightarrow{\cong} M^C_n.$$

2. If $b \geq 0$ and $b + q < 0$ then $H^{*,b+q}_{C_2}(C, \mathbb{Z}/n) \cong H^*_C(\tilde{C}, \mathbb{Z}/n)$. Moreover, Re is identified with the $M^C_n$-module map

$$\bigoplus_{a \leq 2b+1} H^{a+q}_{Br}(\tilde{C}, \mathbb{Z}/n) \to M^C_n.$$

3. If $b < 0$ and $b + q \geq 0$ then $H^{*,b+q}_{C_2}(C, \mathbb{Z}/n) \cong H^*_C(\tilde{C}, \mathbb{Z}/n) \cong M^C_n$.

Moreover Re is identified with the $M^C_n$-algebra map

$$M^C_n \to H^*_Br(\tilde{C}, \mathbb{Z}/n).$$

4. If $b < 0$ and $b + q < 0$, then $H^{*,b+q}_{C_2}(C, \mathbb{Z}/n) = 0$.

**Proof.** We make use of the comparison of long exact sequences, obtained from (2.1) and (2.2)

$$\cdots \to H^{a+p,b+q}(C) \to H^{a+\sigma,b+q}_{C_2}(C) \to H^{a+(p+1)\sigma,b+q}(C) \to H^{a+1+p,b+q}(C) \to \cdots$$

and

$$\cdots \to H^{a+p}_{\text{sing}}(pt) \to H^{a+\sigma}_{Br}(pt) \to H^{a+(p+1)\sigma}_{Br}(pt) \to H^{a+1+p}_{\text{sing}}(pt) \to \cdots$$

$$\cdots \to \tilde{H}^{a \sigma,b+q}_{\text{Br}}(\tilde{C}) \to H^{a \sigma,b+q}_{C_2}(C) \to H^{a \sigma,b+q}_{C_2}(\tilde{C}) \to \cdots$$

First we note that (4) follows since $H^{a,b+q}_{C_2}(\tilde{C}) = 0$ if $b + q < 0$ (see Proposition 3.3) and $\tilde{H}^{a \sigma,b+q}_{\text{Br}}(\tilde{C}) = 0$ if $b < 0$ (see Proposition 2.7).

To establish (1), we first observe that it suffices to show that $H^{a,b+q}_{C_2}(C) \to H^a_{Br}(pt)$ is an isomorphism for all $a$. Indeed the general case follows from the $p = 0$ case by induction (upwards and downwards) on $p$, using (4.2), since $H^{*,a}(C) \to H^*_{\text{sing}}(pt)$ is an isomorphism when $n \geq 0$. Next, we note that using (4.3) together with Proposition 3.2 and Proposition 2.7, we have that $H^{a,b+q}_{C_2}(C) \to H^a_{Br}(pt)$ is an isomorphism for $a \leq 2b$ and that $H^{a,b+q}_{C_2}(C) = 0$ for $a > 2b$. Since $b \geq 0$, for this implies that Re is also an isomorphism for $a > 2b$.

For part (2), consider the commutative diagram

$$\cdots \to \tilde{H}^{a \sigma,b+q}_{C_2}(\tilde{C}) \xrightarrow{\cong} H^{a \sigma,b+q}_{C_2}(C) \to H^a_{Br}(pt).$$

The upper horizontal arrow is an isomorphism since $H^{*,b+q}(\tilde{C}, \mathbb{Z}/n) = 0$ if $b + q < 0$. It follows from Lemma 3.1 and Proposition 2.7 that Betti realization identifies $\tilde{H}^{a \sigma,b+q}_{C_2}(\tilde{C})$ with $\bigoplus_{a \geq 2b+1} H^{a \sigma,b+q}_{Br}(\tilde{C}) \subseteq \tilde{H}^{a \sigma}_{Br}(\tilde{C})$.

The statements of (3) follow from Proposition 2.7 and Theorem 3.6. □
For simplicity, we now restrict to the case of \( \mathbb{Z}/2 \) coefficients, because this is the most interesting case. However, it is straightforward to adapt the following discussion to the general case of \( \mathbb{Z}/p \)-coefficients.

Define

\[
\mu \in H_{C_2}^{0,1-\sigma} (C, \mathbb{Z}/2) \cong \mathbb{Z}/2
\]

to be the generator. (Here we use that \( H_{C_2}^{0,1-\sigma} (C) \cong H_{C_2}^{0,1-\sigma} (EC_2) \).) Also recall that we defined elements \( \xi \in H_{C_2}^{2+2\alpha,-1+\sigma}(C, \mathbb{Z}/2) \) and \( \tau_\sigma \in H_{C_2}^{2\alpha}(C, \mathbb{Z}/2) \) each to be the generator of the displayed group (each of which is equal to \( \mathbb{Z}/2 \)).

**Remark 4.4.** In terms of these elements we have

\[
\tau = \mu \tau_\sigma \in H_{C_2}^{0,1}(C, \mathbb{Z}/2) \cong H_{C_2}^{0,1}(C, \mathbb{Z}/2).
\]

(this can be seen, for example, by noting that \( \text{Re}(\mu \tau_\sigma) = 1 \)).

**Proposition 4.5.** There is an \( M_2^{-2} \)-algebra isomorphism

\[
\phi : M_2^C_2 [\xi, \tau_\sigma, \mu]/(\xi \mu - u^2) \xrightarrow{\cong} \bigoplus_{b,q \geq 0} H_{C_2}^{b+q\sigma} (C, \mathbb{Z}/2)
\]

defined by \( \xi \mapsto \xi \), \( \tau_\sigma \mapsto \tau_\sigma \), \( \mu \mapsto \mu \).

**Proof.** First we note that the relation \( \xi \mu = u^2 \) holds in \( H_{C_2}^{*+0}(C, \mathbb{Z}/2) \), so that there is a well-defined \( M_2^{-2} \)-algebra map \( \phi \). To see that this relation holds, it suffices to note that it holds in \( H_{C_2}^{*+0}(EC_2) \) (since \( H_{C_2}^{*+0}(EC_2) = 0 \)). Now \( \mu \) is the generator of \( H_{C_2}^{0,1-\sigma}(EC_2) \), but by periodicity, this group is also generated by \( u^2 \) (since \( u^2 \) generates \( H_{C_2}^{-2+2\sigma,0}(EC_2) \cong H_{Br}^{-2+2\sigma}(pt) \)).

Examining the weights of elements, we see that

\[
\left( M_2^C_2 [\xi, \tau_\sigma, \mu]/(\xi \mu - u^2) \right)^{(b,q)} \cong \begin{cases} M_2^C_2 \cdot \{ b \} & b \geq 0 \\ M_2^C_2 \cdot \{ q \} & b \leq 0. \end{cases}
\]

If \( b \geq 0 \), consider the commutative diagram

\[
\begin{array}{ccc}
\left( M_2^C_2 [\xi, \tau_\sigma, \mu]/(\xi \mu - u^2) \right)^{(b,q)} & \xrightarrow{\phi} & H_{C_2}^{b+q\sigma} (C, \mathbb{Z}/2) \\
\cong & \cong \text{Re} & \cong \\
& \cong & H_{C_2}^{b+q\sigma} (C, \mathbb{Z}/2)
\end{array}
\]

The right vertical arrow is an isomorphism by **Theorem 4.1** and thus so is \( \phi \). If \( b \leq 0 \), consider the commutative diagram

\[
\begin{array}{ccc}
\left( M_2^C_2 [\xi, \tau_\sigma, \mu]/(\xi \mu - u^2) \right)^{(b,q)} & \xrightarrow{\phi} & H_{C_2}^{b+q\sigma} (C, \mathbb{Z}/2) \\
\cong & \cong & \cong \\
& \cong & H_{C_2}^{b+q\sigma} (EC_2, \mathbb{Z}/2)
\end{array}
\]

The vertical arrow is an isomorphism and therefore, so is \( \phi \).

Next we verify that the module structure on \( \widetilde{H}_{C_2}^{*+0}(EC_2, \mathbb{Z}/2) \), displayed in Figure 5 is the one induced by the isomorphism of the previous proposition.

**Lemma 4.6.** The \( M_2^{-2} \)-module structure on \( \widetilde{H}_{C_2}^{*+0}(EC_2, \mathbb{Z}/2) \), induced by the isomorphism of **Proposition 4.5.**, is determined as follows,

- \( \cdot \tau_\sigma : B_1 \{ \mu \tau_\sigma^2 \} \rightarrow B_1 \{ \mu \tau_\sigma^{2+1} \} \) is the identity.
- \( \cdot \mu : B_1 \{ \mu \tau_\sigma^2 \} \rightarrow B_{1+1} \{ \mu^{2+1} \tau_\sigma^2 \} \) is the inclusion (1.4).
Proposition 4.5, we conclude the Proposition 3.8 with the exception of the . Using defined by \( \xi \)

There is an \( \text{Theorem 4.7.} \)

\[
\begin{align*}
\tilde{H}^{*,b+qr}_{C_2}(\tilde{EC}_2, \mathbb{Z}/2) & \rightarrow \tilde{H}^{*,b+m+(q+n)}_{C_2}(\tilde{EC}_2, \mathbb{Z}/2) \\
\tilde{H}^*_{Br}(\tilde{EC}_2, \mathbb{Z}/2) & \rightarrow \tilde{H}^*_{Br}(\tilde{EC}_2, \mathbb{Z}/2).
\end{align*}
\]

The identification of the module structure follows using that \( \text{Re}(\tau_\sigma) = \text{Re}(\mu) = 1 \) and \( \text{Re}(\xi) = u^2. \)

**Theorem 4.7.** There is an \( M^2_{C_2} \)-algebra isomorphism

\[
M^2_{C_2}[\xi, \tau_\sigma, \mu]/(\xi \mu - u^2) \oplus \left( \bigoplus_{i,j \geq 1} B_i \left( \frac{\mu^i}{\tau^j} \right) \right) \xrightarrow{\cong} H^{*,*}_{C_2}(C, \mathbb{Z}/2).
\]

defined by \( \xi \mapsto \xi, \tau_\sigma \mapsto \tau_\sigma, \mu \mapsto \mu. \) The multiplicative structure on \( H^{*,*}_{C_2}(C, \mathbb{Z}/2) \) is determined as follows.

1. The left hand summand is the displayed quotient of a polynomial ring.
2. Multiplications between elements in the left hand and the right hand summands, are determined by
   \[
   \begin{align*}
   \cdot_{\tau_\sigma} & : B_i \{ \mu^i \tau^j \} \rightarrow B_i \{ \mu^i \tau^{j+1} \}, \text{ for } j \geq 2, \text{ is the identity.} \\
   \cdot_{\tau_\sigma} & : B_i \{ \mu^i \tau^j \} \rightarrow M^2_{C_2} \{ \mu^i \} \text{ is the map (1.5).} \\
   \cdot_{\mu} & : B_i \{ \mu^i \tau^j \} \rightarrow B_{i+1} \{ \mu^{i+1} \tau^j \} \text{ is the inclusion (1.4).} \\
   \cdot_{\xi} & : B_i \{ \mu^i \tau^j \} \rightarrow B_{i-1} \{ \mu^{i-1} \tau^j \} \text{ is (1.6), multiplication by } u^2.
   \end{align*}
\]

3. Products in the right hand summand are trivial.

**Proof.** In Proposition 4.5, we have already identified \( \bigoplus_{b+q \geq 0} H^{*,b+qr}_{C_2}(C) \). To identify the remaining piece, we use that the map \( \bigoplus_{b+q < 0} \tilde{H}^{*,b+qr}_{C_2}(\tilde{EC}_2, \mathbb{Z}/2) \xrightarrow{\cong} \bigoplus_{b+q < 0} H^{*,b+qr}_{C_2}(C, \mathbb{Z}/2) \) is an isomorphism by Proposition 3.3. Using Proposition 3.8, we conclude the \( M^2_{C_2} \)-module structure on \( H^{*,b+qr}_{C_2}(C, \mathbb{Z}/2) \) is as in the theorem. Products in \( \tilde{H}^{*,*}_{C_2}(\tilde{EC}_2, \mathbb{Z}/2) \) are trivial, since they are determined by products in \( \tilde{H}^{*,*}_{C_2}(\tilde{EC}_2, \mathbb{Z}/2) \cong H^{*,*}(\tilde{EC}_2, \mathbb{Z}/2) \), which are trivial. The multiplicative structure involving both the left and right hand summands follows from Lemma 4.6 with the exception of the \( \tau_\sigma \)-multiplications starting in weights \( i - (i+1) \), which follow from the commutative diagram

\[
\begin{align*}
\tilde{H}^{*,-(i+1)\sigma}_{C_2}(\tilde{EC}_2) & \xrightarrow{\cong} H^{*,-(i+1)\sigma}_{C_2}(C) \xrightarrow{\tau_\sigma} H^{*,i-\sigma}_{C_2}(C) \\
\tilde{H}^*_{Br}(\tilde{EC}_2) & \rightarrow \mathbb{M}^2_{C_2} \rightarrow \mathbb{M}^2_{C_2}. 
\end{align*}
\]

\( \square \)
5 Bredon motivic cohomology of algebraically closed fields

In this section we consider an algebraically closed field \( k \) and a natural number \( n > 1 \) coprime to \( \text{char}(k) \). Let \( V \) be a \( C_2 \)-equivariant smooth scheme over \( k \). First we note a rigidity theorem for rational points:

**Theorem 5.1.** For a connected smooth scheme \( X \) over \( k \) and \( k \)-rational points \( x_0, x_1 \) of \( X \),

\[
(x_0)_* = (x_1)_* : H^*_{C_2}(V \times X, \mathbb{Z}/n) \to H^*_{C_2}(V, \mathbb{Z}/n).
\]

According to [19], Theorem 5.1 follows if the functor \( F(-) = H^*_{C_2}(V \times -, \mathbb{Z}/n) \) is a homotopy invariant presheaf on \( Sm/k \) with weak transfers in the sense of [20]. The four conditions that need to be fulfilled according to [19] are:

1) Additivity: For \( X = X_0 \sqcup X_1 \) with corresponding embeddings \( i_m : X_m \hookrightarrow X \) for \( m = 0, 1 \) and \( f : X \to Y \) a map in \( Sm/k \), we have \( f_* = (f_0)_* i_0^* + (f_1)_* i_1^* \).

2) Base change: For every finite flat map \( f \), closed embedding \( g \), and cartesian diagram:

![Diagram](image-url)
we have $g^* f_* = f_1^* g_1^*$.

3) Normalization: If $f$ is the identity map on $k$ then $f_* = id_{H^n_{C_2}(V, \mathbb{Z}/(n))}$.

4) Homotopy invariance: The rational points 0 and 1 of the affine line $\mathbb{A}_k^1$ with trivial $C_2$-action yield equal pullback maps

$$0_* = 1_* : H^n_{C_2}(V \times_k \mathbb{A}_k^1) \to H^n_{C_2}(V).$$

The functor $F$ fulfills all four conditions above as it is a homotopy invariant presheaf with equivariant transfers ([8]). Moreover, because it is a homotopy invariant presheaf with equivariant transfers, according to [13], [19], [20], we have the following theorem:

**Theorem 5.2.** Suppose $k \subset K$ is an extension of algebraically closed fields and $X$ is a smooth $C_2$-equivariant scheme. If $n$ is coprime to char($k$), then $\pi : \text{Spec}(K) \to \text{Spec}(k)$ induces an isomorphism:

$$\pi^* : H^n_{C_2}(X, \mathbb{Z}/(n)) \cong H^n_{C_2}(X_K, \mathbb{Z}/(n)).$$

**Proof.** We can write $\text{Spec}(K) = \lim U(U)$, where $U$ is an affine smooth variety over $\text{Spec}(k)$. There is an induced map

$$\pi^* : H^n_{C_2}(X, \mathbb{Z}/(n)) \to H^n_{C_2}(X \times K, \mathbb{Z}/(n)) = \text{colim} H^n_{C_2}(X \times U, \mathbb{Z}/(n))$$

so if $\pi^*(x) = 0$ then there exists a map $\phi : U \to \text{Spec}(k)$ such that $\phi^*(x) = 0$. Because $U$ has a $k$-rational point, $\phi$ yields a splitting and $\phi^*$ is injective. This implies $x = 0$ so $\pi^*$ is injective.

Next we show that $\pi^*$ is surjective. For every $\beta \in H^{a+p+r, b+q+q}(X \times K)$ there exists a map $\phi : \text{Spec}(k) \to U$ such that $\phi^*(\beta') = \beta$ with $\beta' \in H^{a+1, r+q}(X \times U)$. If $\xi : \text{Spec}(k) \to U$ a rational point, the maps $\xi \circ \pi, \phi : \text{Spec}(K) \to U$ induce $K$-rational points $\phi', \xi' : \text{Spec}(K) \to U_K$. According to Theorem 5.1 we have that

$$\phi'^* = \xi'^* : H^{a+*}(X \times U \times K) \to H^{a+*}(X \times K).$$

For the base change $\pi_1 : U_K \to U$, we have $\beta - \pi^* \circ \xi^*(\beta') = \phi^*(\beta') - \pi^* \circ \xi^*(\beta') = (\phi'^* - \xi'^*)(\pi^*(\beta')) = 0$, and thus $\beta \in \text{Im}(\pi^*)$.

The next corollary computes Bredon motivic cohomology for different algebraically closed fields of characteristic zero.

**Corollary 5.3.** Let $K$ an algebraically closed field of characteristic zero and $n > 1$. Then

$$H^{a+p+r, b+q+q}(K, \mathbb{Z}/(n)) \cong H^{a+p+r, b+q+q}(C, \mathbb{Z}/(n))$$

and

$$H^{a+p+r, b+q+q}(EC_2, \mathbb{Z}/(n)) \cong H^{a+p+r, b+q+q}(EC_2, \mathbb{Z}/(n)),$$

for any choice of integers $a, b, p, q$.
