ABSTRACT
To overcome the influence from deterministic type load disturbance with unknown dynamics, a bias-eliminated subspace identification method is proposed for consistent estimation. By decomposing the output response into three parts, deterministic, disturbed and stochastic components, in terms of the linear superposition principle, an LQ decomposition approach is developed to eliminate the disturbance and noise effect for unbiased estimation of the deterministic system state. Subsequently, a shift-invariant approach is given to retrieve the state matrices. Consistent estimation on the state matrices is analyzed with a proof. Illustrative example of open-loop system identification is shown to demonstrate the effectiveness and merit of the proposed method.

Subspace identification; load disturbance; Kalman innovation form; LQ decomposition; consistent estimation

1. Introduction
Subspace identification methods (SIMs) have been continuously developed in the last three decades, owing to uniform state-space description of multiple-input multiple-output (MIMO) systems for control system design such as model predictive control (MPC). There are a few well recognized subspace identification methods for practical application, e.g. the CVA approach (Larimore, 1990), the MOESP method (Verhaegen & Dewilde, 1992), the N4SID algorithm (Overschee & Moor, 1994), and the IVM algorithm (Viberg, 1995). It was clarified in the reference (Overschee & Moor, 1995) that some of these SIMs are equivalent to each other besides the use of different weights for data matrix analysis. The asymptotic properties of these SIMs were investigated in the references (Bauer, 2009; Bauer & Jansson, 2000; Chiuso & Picci, 2004).

For closed-loop system identification, the plant input is correlated with the output measurement noise due to the feedback mechanism, which may result in biased estimation if using the above SIMs based on open-loop identification tests. Closed-loop SIMs have therefore been explored to ensure consistent estimation in the recent years. The closed-loop SIMs can be roughly classified into three types: 1. The instrumental variable (IV) based SIMs, e.g. SSARX (Jansson, 2003), WFA (Chiuso & Picci, 2005), and PBSID-opt (Chiuso, 2007), where a high order ARX model was used to estimate the Markov parameters; 2. The innovation pre-estimation based SIMs, e.g. PARSIM-E (Qin & Ljung, 2003), PARSIM-K (Pannocchia & Calosi, 2010), and OKID-rw (Phan, Horta, Juang, & Longman, 1995), where the innovation sequence was pre-estimated to avoid correlation between the input and noise for Markov parameter estimation.

Note that many industrial processes and system operations suffer from deterministic type load disturbance which may occur randomly with varying magnitude or lasting time, such as the injection velocity response of a polymer injection moulding machine during the mould filling process (Liu, Zhou, Yang, & Gao, 2010). However, there are only a few papers that propose bias-eliminated SIMs method against certain types of load disturbance. To deal with a deterministic type disturbance with continuous-time dynamics, a bias-eliminated SIM was proposed (Liu, Huang, & Qin, 2015) which required a fixed occurrence time of load disturbance such that effective approximation along the time sequence could be obtained. Concerning periodic type disturbance, a difference operator was proposed to remove the disturbance effect for consistent estimation (Houtzager, van Wingerden, & Verhaegen, 2013).
In this paper, a bias-eliminated SIM is proposed to cope with load disturbance that may occur randomly with unknown dynamics but finally settle down to a steady value or zero as often encountered in engineering practice. The proposed SIM can be used for both open and closed-loop system identification in the presence of such disturbance. To identify the deterministic system response, the output response is decomposed into three parts, deterministic, disturbed and stochastic components, based on the linear superposition principle. Correspondingly, an LQ decomposition approach is developed to eliminate the influence from load disturbance and stochastic noise, such that unbiased estimation can be obtained for the deterministic system state. Consequently, a shift-invariant approach is given to retrieve the state matrices from the state estimation.

For clarity, the paper is organized as follows. In Section 2, the problem description is briefly stated. The proposed SIM for state estimation is presented in Section 3. In Section 4, consistent estimation is analyzed with a strict proof. Two illustrative examples are shown in Section 5. Finally, some conclusions are drawn in Section 6.

Throughout this paper, the following notations and operations will be used: \( \mathbb{R}^{m \times n} \) denotes a real matrix space, while \( \mathbb{R}^n \) denotes a real vector. Subscript \( I \) (or 0) denotes an matrix with appropriate dimension. The identity (or zero) vector/matrix with appropriate dimensions is denoted by \( I (or 0) \), while \( I_m (or 0_m \times n) \) means \( I_m \in \mathbb{R}^{m \times m} (or 0_m \times n \in \mathbb{R}^{m \times n}) \). For any matrix \( P \in \mathbb{R}^{m \times m} \) of full rank, denote by \( P^{-1} \) the inverse of \( P \), by \( P^T \) the transpose of \( P \), and by \( \| P \|_2 \) the matrix 2-norm. For \( P \in \mathbb{R}^{m \times n} \) of full row (or column) rank, \( P^T \) denotes the Moore-Penrose pseudo-inverse of \( P \). Denote by \( \tilde{P} \) an estimate of \( P \). For \( Q_1 \in \mathbb{R}^{p \times q}, Q_2 \in \mathbb{R}^{p' \times q}, \) and \( Q_3 \in \mathbb{R}^{q' \times q} \) with appropriate dimensions, the orthogonal complement of the row space of \( Q_1 \) is denoted by \( Q_1^\perp \).

2. Problem description

For an industrial process subject to load disturbance, consider the following state-space model of predictor form,

\[
S : \begin{align*}
x(t + 1) &= Ax(t) + Bu(t) + w(t) \\
y(t) &= Cx(t) + v(t)
\end{align*}
\( \tag{1} \)

where \( u(t) \in \mathbb{R}^{nu}, x(t) \in \mathbb{R}^{nx}, y(t) \in \mathbb{R}^{ny} \) denote the input, process state, and output measurement, respectively; \( A, B, C \) are the state matrices with appropriate dimensions and \( w(t) \in \mathbb{R}^{nw} \) indicates an unknown load disturbance which has deterministic dynamics and settles down to a steady value including zero (due to feedback mechanism in a close-loop system) within a finite time, i.e. \( w(t) = 0 \) for \( t > t_{d_w} \) where \( t_{d_w} \) denotes a finite time length, as often encountered in engineering practice; \( v(t) \in \mathbb{R}^{nv} \) denotes the output measurement noise which is assumed to be a Gaussian white noise with zero mean and unknown variance, while assuming that \( w(t) \) and \( v(t) \) are uncorrelated, i.e. \( E[w(t)v^T(t)] = 0 \).

Assume that the system description in (1) is minimal in the sense that \( (A, B) \) is reachable and \( (A, C) \) is observable. It may be transformed into the Kalman innovation form,

\[
S_K : \begin{align*}
\dot{x}(t + 1) &= A\hat{x}(t) + Bu(t) + \omega(t) + Ke(t) \\
y(t) &= C\hat{x}(t) + e(t)
\end{align*}
\( \tag{2} \)

where \( \hat{x}(t) \) denotes the estimated state and \( K \) is the Kalman filter gain; The innovation \( e(t) \) is a zero-mean white noise which is independent of the input \( u(k) \) and output \( y(k) \) for \( k < t \). For the convenience of analysis, in the rest of this paper \( x(t) \) is used instead of \( \hat{x}(t) \).

Denote \( \bar{A} = A - KC \), the innovation form in (2) can also be represented by the equivalent predictor form,

\[
S_p : \begin{align*}
x(t + 1) &= \bar{A}x(t) + Bu(t) + \omega(t) + Ky(t) \\
y(t) &= Cx(t) + e(t)
\end{align*}
\( \tag{3} \)

where all the eigenvalues of \( \bar{A} \) lie inside the unit circle.

Without loss of generality, the predictor form in (3) is studied herein for model identification, which can be applied for both an open-loop process and a closed-loop system.

We decompose the system state into deterministic and disturbed components in terms of the linear superposition principle,

\[
x(t) = x_u(t) + x_d(t)
\( \tag{4} \)

where \( x_u(t) \) denotes the state response arising from the input \( u(t) \), and \( x_d(t) \) is the disturbance response.

Correspondingly, the output response is decomposed into three parts, deterministic, disturbed and stochastic components, i.e.

\[
y(t) = y_u(t) + y_d(t) + y_s(t)
\( \tag{5} \)

where \( y_u(t) \) denotes the output arising from measurement noise \( v(t) \), i.e. \( y_u(t) = e(t) \).

Therefore, the system description in (3) can be decomposed into two subsystems, namely deterministic \( (S_u) \) and disturbed \( (S_d) \) subsystems, as below

\[
S_u : \begin{align*}
x_u(t + 1) &= \bar{A}x_u(t) + Bu(t) + Ky(t) \\
y_u(t) &= Cx_u(t)
\end{align*}
\( \tag{6} \)

\[
S_d : \begin{align*}
x_d(t + 1) &= \bar{A}x_d(t) + B\Delta u(t) \\
y_d(t) &= Cx_d(t)
\end{align*}
\( \tag{7} \)

where \( \Delta u(t) = B\Delta u(t) \) is assumed to facilitate analysis, with \( \Delta u(t) \) being regarded as the disturbance input that
is unknown and time-varying, but finally recovers to a steady value including zero, i.e. $\Delta u(t) = 0$.

The identification task is therefore formulated as estimating the system matrices $(A, B, C)$ from the deterministic subsystem $(S_d)$ while eliminating the influence from the disturbed $(S_d)$ subsystem and the innovation from measurement noise $(e(t))$.

3. Bias-eliminated subspace identification

Based on the above system description, a two-step SIM method is proposed for bias-eliminated model identification. The first step is estimation of the deterministic state and the second step is identification of the state matrices, which are detailed in the following subsections, respectively.

3.1. State estimation

Denote by $p$ and $f$ the past and future horizons. The past and future input stacked vectors are defined, respectively, by

$$u_p(t) = [u(t-p)^T, \ldots, u(t-2)^T, u(t-1)^T]^T$$

$$u_f(t) = [u(t)^T, \ldots, u(t+f-2)^T, u(t+f-1)^T]^T$$

Similar definitions are given for $y_p(t), y_f(t), \Delta u_p(t), \Delta u_f(t), e_p(t)$, and $e_f(t)$.

Correspondingly, the past and future input block-Hankel matrices are denoted by

$$U_p = [u_p(t), u_p(t+1), \ldots, u_p(t+N-1)]$$

$$U_f = [u_f(t), u_f(t+1), \ldots, u_f(t+N-1)]$$

Similar definitions are given for $Y_p, Y_f, \Delta U_p, \Delta U_f, E_p$ and $E_f$.

By iterating (3) using the above definitions on the ‘past’ and ‘future’ sequences, we obtain

$$x(t) = \bar{A}^p x(t-p) + L[u_p^T(t) y_p^T(t)]^T + L_1 \Delta u_p(t)$$

$$y_f(t) = \Gamma x(t) + H u_{f-1}(t) + G y_{f-1}(t) + e_f(t)$$

where the initial state is regarded as $x(k-p)$.

The extended observability matrix and the lower triangular Toeplitz matrices are, respectively,

$$\Gamma = [C^T, \bar{A}^T C^T, \ldots, (\bar{A}^{f-1} C^T)]^T$$

$$H = \begin{bmatrix} H_1 \\ H_2 \\ \vdots \\ H_f \end{bmatrix} = \begin{bmatrix} 0 & \cdots & 0 \\ CB & \cdots & 0 \\ \vdots & \ddots & \vdots \\ C\bar{A}^{f-2} B & \cdots & CB \end{bmatrix}$$

$$G = \begin{bmatrix} G_1 \\ G_2 \\ \vdots \\ G_f \end{bmatrix} = \begin{bmatrix} 0 & \cdots & 0 \\ CK & \cdots & 0 \\ \vdots & \ddots & \vdots \\ C\bar{A}^{f-2} K & \cdots & CK \end{bmatrix}$$

When $p$ is sufficiently large, there exists $\bar{A}^p \rightarrow 0$ as can be verified from (3). Correspondingly, substituting (12) into (13) yields

$$y_f(t) = \Gamma L_1 [u_p(t) + \Delta u_p(t)] + \Gamma L_2 y_p(k) + H[u_{f-1}(t) + \Delta u_{f-1}(t)] + G y_{f-1}(t) + e_f(t)$$

where

$$\Gamma L_1 = \begin{bmatrix} [\Gamma L_1]_1 \\ [\Gamma L_1]_2 \\ \vdots \\ [\Gamma L_1]_f \end{bmatrix} = \begin{bmatrix} C\bar{A}^{p-1} B & \cdots & \bar{A} B & CB \\ \bar{C} A^p B & \cdots & \bar{C} A^2 B & \bar{C} A B \\ & \ddots & \ddots & \ddots \\ & & & \bar{C} \bar{A}^{f-p-2} B & \cdots & \bar{C} A^{f-1} B & \bar{C} \bar{A}^{f-1} B \end{bmatrix}$$

$$\Gamma L_2 = \begin{bmatrix} [\Gamma L_2]_1 \\ [\Gamma L_2]_2 \\ \vdots \\ [\Gamma L_2]_f \end{bmatrix} = \begin{bmatrix} C\bar{A}^{p-1} K & \cdots & \bar{A} K & CK \\ \bar{C} A^p K & \cdots & \bar{C} A^2 K & \bar{C} A K \\ & \ddots & \ddots & \ddots \\ & & & \bar{C} \bar{A}^{f-p-2} K & \cdots & \bar{C} A^{f-1} K & \bar{C} \bar{A}^{f-1} K \end{bmatrix}$$

It follows from (17) that

$$Y_f = \Gamma L_1 (U_p + \Delta U_p) + \Gamma L_2 Y_p + H(U_{f-1} + \Delta U_{f-1}) + G Y_{f-1} + E_f$$

Note that the last $n_f$ rows of $Y_f$ are in the form of

$$Y_{f(i)} = [y(t+f-1), y(t+f), \ldots, y(t+f+N-2)]$$

It can be seen from (20) that

$$Y_{f(i)} = [\Gamma L_1]_r (U_p + \Delta U_p) + [\Gamma L_2]_r Y_p + H_{i-1} (U_{f-1} + \Delta U_{f-1}) + G_{i-1} Y_{f-1} + E_{f(i)}$$

where $E_{f(i)} = [e(t+f-1), e(t+f), \ldots, e(t+f+N-2)]$. 

---

**SYSTEMS SCIENCE & CONTROL ENGINEERING: AN OPEN ACCESS JOURNAL**
In view of that \([\Gamma L_1]_r, [\Gamma L_2]_r, H_r, \) and \(G_r\) contain all of the Markov parameters in \(\Gamma L, H\) and \(G,\) model identification is therefore focused on (22) so as to avoid redundant estimation.

Based on the subsystem descriptions in (6) and (7), we decompose \(Y_{f(i)}\) into three parts, the deterministic output denoted by \(Y_{df(i)}\), the disturbed output denoted by \(Y_{d,i}\), and the stochastic output denoted by \(E_{f(i)}\), i.e.

\[
Y_{f(i)} = Y_{df(i)} + Y_{d,i} + E_{f(i)} \tag{23}
\]

It can be derived from (22) that

\[
Y_{df(i)} = [[\Gamma L_1]_r \ H_r \ [\Gamma L_2]_r \ G_r][U_p^T \ U_{f-1}^T \ Y_p^T \ Y_{f-1}^T]^T \tag{24}
\]

\[
Y_{d,i} = [[\Gamma L_1]_r \ H_r] [\Delta U_p^T \ \Delta U_{f-1}^T]^T \tag{25}
\]

Since the load disturbance response becomes a steady value after the time \(t_{dy},\) i.e. \(y_d(t + f + m - 2) = \ldots = y_d(t + f + N - 2),\) where \(m = t_{dy} - t - f + 2,\) the disturbance response can be written as

\[
Y_{d,i} = \theta_{yd} \phi_N \tag{26}
\]

where

\[
\theta_{yd} = [y_d(t + f - 1), \ldots, y_d(t + f + m - 3)] \in \mathbb{R}^{ny \times m},
\]

\[
\phi_N = \begin{bmatrix} I_{m-1} & 0_{(m-1) \times (N-m+1)} & 0_{1 \times (N-m+1)} \end{bmatrix} \quad \text{for } m > 1.
\]

**Remark 1:** For \(m = 1,\) it means that the disturbance is a constant type, which is indeed a special case of a deterministic type disturbance. Since the dynamics of load disturbance is often unknown in practice, it is suggested to take \(m\) as a sufficiently large value to ensure that the disturbance response has recovered to a steady value at the time step \(k - p + m - 1\), for which the effectiveness can be verified by comparing the identification results based on taking different values of \(m.\)

Substituting (24) and (26) into (23), we obtain

\[
Y_{f(i)} = \theta_1 Z + \theta_{yd} \phi_N + E_{f(i)} \tag{27}
\]

where

\[
Z = [U_p^T \ U_{f-1}^T \ Y_p^T \ Y_{f-1}^T]^T \tag{28}
\]

\[
\theta_1 = [[\Gamma L_1]_r \ H_r \ [\Gamma L_2]_r \ G_r] \tag{29}
\]

\[
\phi_N = \begin{bmatrix} I_{m-1} & 0_{(m-1) \times (N-m+1)} & 0_{1 \times (N-m+1)} \end{bmatrix} \in \mathbb{R}^{ny \times N} \quad \text{for } m > 1. \tag{30}
\]

By performing a LQ decomposition on \([Z^T \ \phi_N^T \ Y_{f(i)}^T]^T,\) we have

\[
\begin{bmatrix} Z \\ \phi_N \\ Y_{f(i)} \end{bmatrix} = \begin{bmatrix} \theta_1 & 0 & 0 \\ 0 & \theta_{yd} & 0 \\ 0 & 0 & \theta_{yr} \end{bmatrix} \begin{bmatrix} Q_1^T \\ Q_2^T \\ Q_3^T \end{bmatrix} \tag{31}
\]

where \(\theta_{yd} \in \mathbb{R}^{ny \times (f+p-1)ny}, \theta_{yr} \in \mathbb{R}^{ny \times m},\) and \(\theta_{yr} \in \mathbb{R}^{ny \times (f+p-1)nu}.

By postmultiplying \(Q_1\) to both sides of (31), we obtain

\[
Y_{f(i)} Q_1 = \theta_1 Z Q_1 + \theta_{yd} \phi_N Q_1 + E_{f(i)} Q_1 \tag{32}
\]

In the same way, we postmultiply \(Q_2\) to both sides of (31), obtaining

\[
Y_{f(i)} Q_2 = \theta_1 Z Q_2 + \theta_{yd} \phi_N Q_2 + E_{f(i)} Q_2 \tag{33}
\]

According to (31), there are

\[
Y_{f(i)} Q_1 = R_{31}, \quad Z Q_1 = R_{31}, \quad \phi_N Q_1 = R_{31} \tag{34}
\]

\[
Y_{f(i)} Q_2 = R_{32}, \quad Z Q_2 = 0, \quad \phi_N Q_2 = R_{32} \tag{35}
\]

Substituting (34) and (35) into (32) and (33) respectively yields

\[
R_{31} = \theta_1 R_{11} + \theta_{yd} R_{21} + E_{f(i)} Q_1 \tag{36}
\]

\[
R_{32} = \theta_{yd} R_{22} + E_{f(i)} Q_2 \tag{37}
\]

In view of that \(E_{f(i)}\) is uncorrelated with either \(Z\) or \(\phi_N,\) it follows from (36) and (37) that

\[
R_{31} = \theta_1 R_{11} + \theta_{yd} R_{21} \tag{38}
\]

\[
R_{32} = \theta_{yd} R_{22} \tag{39}
\]

Therefore, an estimate of \(\theta_1\) can be derived from (38) and (39) as

\[
\hat{\theta}_1 = (R_{31} - R_{32} R_{22}^{-1} R_{21}) R_{11}^{-1} \tag{40}
\]

Denote

\[
\hat{\theta}_1 = [\alpha_{f,p-1}, \ldots, \alpha_{1}, \beta_{f,p-1}, \ldots, \beta_{1}] \tag{41}
\]

where \(\alpha_i \in \mathbb{R}^{nym \times 2(f+p-1)nu}\) and \(\beta_i \in \mathbb{R}^{nym \times 2(f+p-1)nu}.\)
Using (18) and (19), the estimates of $\Gamma L_1$ and $\Gamma L_2$ are retrieved from $\hat{\theta}_1$ in (29) as follows

$$
\hat{\Gamma} \hat{L}_1 = \begin{bmatrix}
\alpha_1 & \cdots & \alpha_2 & \alpha_1 \\
\alpha_5 & \cdots & \alpha_6 & \alpha_2 \\
\vdots & \ddots & \vdots & \vdots \\
\alpha_{p-1} & \cdots & \alpha_p & \alpha_1
\end{bmatrix}
$$

(42)

$$
\hat{\Gamma} \hat{L}_2 = \begin{bmatrix}
\beta_1 \\
\beta_2 \\
\vdots \\
\beta_{r+1}
\end{bmatrix}
$$

(43)

Correspondingly, the product of the extended observability matrix and the deterministic state is estimated using (13) and (20) as

$$
\hat{\Gamma} \hat{X}_u = \hat{\Gamma} [\hat{L}_1 \hat{L}_2] [U_p] \gamma_p^T
$$

(44)

where the deterministic state is $X_u = [x_u(t), x_u(t+1), \ldots, x_u(t+N-1)]$. A similar definition is given for $X_d$.

Performing a singular value decomposition (SVD) on (44), we obtain

$$
\hat{\Gamma} \hat{X}_u^{SVD} = \begin{bmatrix}
\hat{U}_1 & \hat{U}_2
\end{bmatrix} \begin{bmatrix}
\Sigma_1 \\
\Sigma_2
\end{bmatrix}
\begin{bmatrix}
\hat{V}_1^T \\
(V_2^T)
\end{bmatrix}
$$

(45)

where $\hat{V}_1$ corresponds to the front $n_x$ eigenvalues of $\hat{\Gamma} \hat{X}_u$.

Hence, the deterministic subsystem state is estimated as

$$
\hat{X}_u = \hat{V}_1^T T
$$

(46)

Remark 2: Given the input and output observation data, there may be different state-space realizations, all of which are related to each other by a similarity transformation matrix $T$. Without loss of generality, it is suggested to take $T = I$ for simplicity.

### 3.2. Identification of the state matrices

Denote $J_1 = [0_{1 \times 1} I_{N-1}]^T$, $J_2 = [I_{N-1} 0_{1 \times 1}]^T$, $J_{ny} = [J_{ny} = [J_{ny} 0_{ny-1 \times (f-1) n_y}]$, $J_{ny} = [J_{ny} 0_{ny-1 \times (f-1) n_y}]^T$, and $J_{nu} = [J_{nu} 0_{nu-1 \times (f-1) n_u}]$. By iterating (5), (6) and (7) using the input and output observation data, we have

$$
J_{ny} Y_{fJ} = C(X_u + X_d)J_2 + J_{nu} E_{fJ} J_2
$$

(47)

$$
X_uJ_1 = \ddot{A}X_uJ_2 + BJ_{na}U_J J_2 + K_{ny} Y_{fJ} J_2
$$

(48)

Similar to (26), the disturbed state response can be written as

$$
X_dJ_2 = \theta_d(\varphi) \varphi_1
$$

(49)

where $\varphi = [x_d(t), \ldots, x_d(t + m - 1)]$, and

$$
\varphi = \begin{bmatrix}
I_{m-1} & 0_{(m-1) \times (N-m)} & 1_{1 \times (N-m)}^T
\end{bmatrix} \in \mathbb{R}^{m \times (N-1)}
$$

Denote two short-hands,

$$
\psi_1 = \begin{bmatrix}
\tilde{U}_2 X_u^T J_2 & \tilde{J}_2 \tilde{U}_2^T J_2 & \tilde{J}_2 \tilde{V}_1^T J_2
\end{bmatrix}
$$

(50)

$$
\theta_2 = [\tilde{A} \tilde{B} \tilde{K}]
$$

(51)

It follows from (47) and (48) that

$$
X_uJ_1 = \theta_2 \psi_1
$$

(52)

$$
J_{ny} Y_{fJ} J_2 = C X_u J_2 + C \theta_d(\varphi) \varphi_1 + J_{ny} E_{fJ} J_2
$$

(53)

The least-squares (LS) estimates of $\theta_2$ and $\tilde{C}$ are therefore obtained as

$$
\tilde{\theta}_2 = \tilde{X}_{nu} J_1 \hat{\psi}_1 \hat{\psi}_1^{-1}
$$

(54)

$$
\hat{\tilde{C}} = J_{ny} Y_{fJ} J_2 \Sigma_{n_y-1}^{-1} J_2 \tilde{X}_{nu} J_1 \hat{\psi}_1 \hat{\psi}_1^{-1}
$$

(55)

Based on the estimates of $\hat{A}$, $\hat{\tilde{B}}$ and $\hat{\tilde{K}}$ from $\tilde{\theta}_2$, the state matrix $A$ can be estimated from the relationship $A = \tilde{A} - K \tilde{C}$ as

$$
\hat{A} = \hat{\tilde{A}} + \hat{\tilde{K}} \hat{\tilde{C}}
$$

(56)

Remark 3: The disturbance effect on the deterministic state and output, $\theta_{\varphi_d}$ and $\theta_{\varphi_d}$, can be similarly estimated as above, which may be used to estimate the dynamics of load disturbance in terms of the decomposed subsystem in (7), therefore facilitating model validation.

### 4. Consistent convergence analysis

The estimation error on $\hat{\theta}_1$ can be computed by (36) and (40) as

$$
\Delta \varphi_1 = \hat{\varphi}_1 - \varphi_1 = E_{f_1} Q_1 R_{11}^{-1} - E_{f_0} Q_2 R_{22}^{-1} R_{21} R_{11}^{-1}
$$

(57)

Recall that the innovation $e(t)$ is a zero-mean white noise which is independent of the input $u(k)$ and output $y(k)$ for $k < t$. Thus, the innovation process $E_{f_1}$ is uncorrelated with the past inputs and outputs and future inputs. Meanwhile, the innovation process $E_{f_0}$ is uncorrelated with $\varphi$, i.e.

$$
\lim_{N \to \infty} \frac{1}{N} E_{f_1} [Z^T \varphi] = 0
$$

(58)

Moreover, it follows from (31) that

$$
\begin{bmatrix}
\varphi \\ \varphi \\ \varphi \\ \varphi
\end{bmatrix}
= \begin{bmatrix}
R_{11} & 0_{1 \times (N-1)} & 0_{1 \times (N-1)}^T \\ R_{21} & R_{22}
\end{bmatrix}
$$

(59)

where $R_{11}$ and $R_{22}$ are nonsingular.
Hence, we have
\[ \lim_{N \to \infty} \frac{1}{N} E[f(i)[Q_1 \ Q_2] = 0 \] (60)

This implies that the orthogonal matrices \( Q_1^T \) and \( Q_2^T \) are uncorrelated with the future noise \( E[f(i)] \).

It follows from (57) and (60) that
\[ \lim_{N \to \infty} \Delta \theta_1 = 0 \] (61)

The estimation error of \( \hat{\Gamma}_1 \) and \( \hat{\Gamma}_2 \) can be derived from (42) and (43),
\[ \Delta \Gamma_1 = \hat{\Gamma}_1 - \Gamma_1 \] (62)
\[ \Delta \Gamma_2 = \hat{\Gamma}_2 - \Gamma_2 \] (63)

It follows from (62) and (63) that
\[ \hat{\Gamma}_1 = \begin{bmatrix} \alpha_1 \\ \vdots \\ \alpha_p \end{bmatrix} = \hat{\theta}_1 \alpha_1 \] (64)
\[ \hat{\Gamma}_2 = \begin{bmatrix} \beta_1 \\ \vdots \\ \beta_p \end{bmatrix} = \hat{\theta}_1 \beta_1 \] (65)

where \( \hat{\theta}_1 \) consists of \( \hat{\theta}_1 \) with a multiple number of \( f \), i.e.
\[ \hat{\theta}_1 = \begin{bmatrix} \hat{\theta}_1 \\ \vdots \\ \hat{\theta}_1 \end{bmatrix}^T \] (66)

and
\[ H_1 = [H_{11} \ H_{12} \ldots \ H_{1f}]^T \] (67)
\[ H_2 = [H_{21} \ H_{22} \ldots \ H_{2f}]^T \] (68)
\[ H_{1i} = [0_{f-1} \ 1_1 \ 0_{f-p+i-2}]^T, \quad i = 1, 2, \ldots, f \] (69)
\[ H_{2i} = [0_{f-1} \ 1_p \ 0_{f-p+i-1}]^T, \quad i = 1, 2, \ldots, f \] (70)

Similarly, we obtain
\[ \Gamma L_1 = \theta_11 H_1 \] (71)
\[ \Gamma L_2 = \theta_11 H_2 \] (72)

where \( H_1 \) and \( H_2 \) are totally the same as the \( H_1 \) and \( H_2 \) in (64) and (65), and \( \theta_11 \) consists of \( \theta_1 \) with a multiple number of \( f \), i.e.
\[ \theta_11 = [\theta_1 \ \ldots \ \theta_1]^T \] (73)

By substituting (64) and (71) into (62), we have
\[ \Delta \Gamma L_1 = \hat{\Gamma}_1 L_1 - \Gamma L_1 = \hat{\theta}_11 \alpha_1 - \theta_11 \alpha_1 = \Delta \theta_11 L_1 \] (74)

Similarly, by substituting (65) and (72) into (63), we have
\[ \Delta \Gamma L_2 = \hat{\Gamma}_2 L_2 - \Gamma L_2 = \hat{\theta}_11 \beta_1 - \theta_11 \beta_1 = \Delta \theta_11 L_2 \] (75)

where the \( \Delta \theta_11 \) is consist of \( \Delta \theta_1 \) and its number is \( f \), i.e.
\[ \Delta \theta_11 = [\Delta \theta_1 \ \ldots \ \Delta \theta_1]^T \] (76)

Therefore, it can be seen from (73), (74) and (61) that
\[ \lim_{N \to \infty} \Delta \Gamma L_1 = 0 \] (77)
\[ \lim_{N \to \infty} \Delta \Gamma L_2 = 0 \] (78)

The estimation error on \( \hat{\Gamma} \mathbf{X}_u \) can be computed by using (44) as
\[ \Delta \Gamma \mathbf{X}_u = \hat{\Gamma} \mathbf{X}_u - \Gamma \mathbf{X}_u = [\Delta \Gamma L_1 \ \Delta \Gamma L_2] [\mathbf{U}_p \ \mathbf{Y}_p]^T \] (79)

Clearly, it can be seen from (77) and (78) that
\[ \lim_{N \to \infty} \Delta \Gamma \mathbf{X}_u = 0 \] (80)

Take the SVD of \( \Gamma \mathbf{X}_u \) in the form of
\[ \Gamma \mathbf{X}_u = \begin{bmatrix} \mathbf{U}_1 \ \mathbf{U}_2 \end{bmatrix} \left[ \begin{array}{cc} \Sigma_1 & 0 \\ 0 & 0 \end{array} \right] \left[ \begin{array}{c} \mathbf{V}_1^T \\ (\mathbf{V}_1^L)^T \end{array} \right] = \mathbf{U}_1 \Sigma_1 \mathbf{V}_1^T \] (81)

The estimation error of \( \hat{\mathbf{X}}_u \) can be computed by using (46) with the same \( T = I \) as
\[ \Delta \mathbf{X}_u = \hat{\mathbf{X}}_u - \mathbf{X}_u = \hat{\mathbf{V}}_1^T - \mathbf{V}_1^T = \Delta \mathbf{V}_1^T \] (82)

It follows from (45) that
\[ \hat{\mathbf{X}}_u = \mathbf{U}_1 \Sigma_1 \mathbf{V}_1^T + \mathbf{U}_2 \Sigma_2 (\mathbf{V}_1^L)^T \] (83)

By premultiplying \( \mathbf{U}_1^T \) and postmultiplying \( \mathbf{V}_1^T \) to both sides of (83), and using \( \mathbf{U}_1^T \mathbf{U}_1 = I \) and \( \mathbf{V}_1^T \mathbf{V}_1^L = 0 \), we obtain
\[ \mathbf{U}_1^T \Delta \mathbf{X}_u \mathbf{V}_1^T = \mathbf{U}_1^T \Delta \hat{\mathbf{X}}_u \mathbf{V}_1^T \] (84)

Also, by premultiplying \( \mathbf{U}_1^T \) and postmultiplying \( \mathbf{V}_1^T \) to both sides of (83), and using \( \mathbf{U}_1^T \mathbf{U}_1 \Sigma_2 (\mathbf{V}_1^L)^T = 0 \), we
obtain
\[ \hat{U}_1^T \hat{\Gamma} \hat{\chi}_u V_1^T = \hat{\Sigma}_1 \hat{V}_1^T V_1^T \]  \(\text{(85)}\)

Since \( \Delta V_1^T = \hat{U}_1^T - V_1^T \), it can be easily derived that
\[ \hat{\Sigma}_1 \Delta V_1^T V_1^T = \hat{\Sigma}_1 \hat{V}_1^T V_1^T \]  \(\text{(86)}\)

It follows from (84), (85) and (86) that
\[ \hat{V}_1^T \Delta \chi_{u}(k) V_1^T = \hat{\Sigma}_1 \Delta V_1^T V_1^T \]  \(\text{(87)}\)

Substituting \( \hat{U}_1^T = U_1^T + \Delta U_1^T \) and \( \hat{\Sigma}_1 = \Sigma_1 \Delta \Sigma_1 \) into (87) yields
\[ (U_1^T + \Delta U_1^T) \Delta \chi_{u}(k) V_1^T = (\Sigma_1 + \Delta \Sigma_1) \Delta V_1^T V_1^T \]  \(\text{(88)}\)

It follows from (88) that
\[ U_1^T \Delta \chi_{u}(k) V_1^T = \Sigma_1 \Delta V_1^T V_1^T + \Delta \Sigma_1 \Delta V_1^T V_1^T \]  \(\text{(89)}\)

By neglecting the second term of a higher order infinitesimal with respect to \( \| \Delta \chi_{u}(k) \| ^2 \) in (89), we have
\[ \Delta V_1^T = \Sigma_1^{-1} U_1^T \Delta \chi_{u} + O(\| \Delta \chi_{u} \|^2) \]  \(\text{(90)}\)

The estimation error on \( \hat{\chi}_u \) can be computed by using (82) and (90) as
\[ \Delta \chi_{u} = \Sigma_1^{-1} U_1^T \Delta \chi_{u} + O(\| \Delta \chi_{u} \|^2) \]  \(\text{(91)}\)

According to (80), we have
\[ \lim_{N \to \infty} \Delta \chi_{u} = 0 \]  \(\text{(92)}\)

Using (47) and (48), we obtain
\[ J_n \gamma J_2 = C(\hat{\chi}_u - \Delta \chi_{u}) J_2 + C \theta \phi_{N-1} + J_n \gamma J_2 \]  \(\text{(93)}\)

\[ (\hat{\chi}_u - \Delta \chi_{u}) J_1 = \hat{A}(\hat{\chi}_u - \Delta \chi_{u}) J_2 + B J_n \gamma J_2 + K J_n \gamma J_2 \]  \(\text{(94)}\)

The estimation errors on \( \hat{\theta}_2 \) and \( \hat{\chi} \) can therefore be derived, respectively, as
\[ \Delta \theta_2 = (\Delta \chi_{u} J_1 - \hat{A} \Delta \chi_{u} J_2) \psi_1^T \]  \(\text{(95)}\)

\[ \Delta C = (J_n \gamma J_2 - C \Delta \chi_{u} J_2) \Pi_{\phi_{N-1}} J_2^T \hat{\chi}_u J_2 \Pi_{\phi_{N-1}} J_2^T \hat{\chi}_u J_2 \]  \(\text{(96)}\)

By omitting the second order infinitesimal with respect to \( \| \Delta \chi_{u}(k) \|^2 \) involved with the above computation, there follows
\[ \lim_{N \to \infty} \Delta \theta_2 = 0 \]  \(\text{(97)}\)

In view of that \( e(t) \) is uncorrelated with the deterministic system state \( x_u(t) \), there is
\[ \lim_{N \to \infty} J_n \gamma J_2 \Pi_{\phi_{N-1}} J_2^T \hat{\chi}_u J_2 = 0 \]  \(\text{(98)}\)

\[ \lim_{N \to \infty} \hat{\hat{\theta}} = 0 \]  \(\text{(99)}\)

Hence, it can be concluded that the estimates on \( \hat{A}, \hat{B}, \hat{C} \) and \( \hat{K} \) are surely consistent for \( N \to \infty \).

\section{5. Illustration}

Consider an injection moulding process studied in the references (Liu et al., 2015),
\[ x(t + 1) = \begin{bmatrix} 1.582 & -0.592 \\ 1 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 1 \end{bmatrix} u(t) + \begin{bmatrix} 1 \end{bmatrix} \sigma(t) \]
\[ y(t) = \begin{bmatrix} 1.69 \\ 1.419 \end{bmatrix} x(t) + v(t) \]

where \( \sigma(t) \) denotes an inherent type load disturbance arising from the mould cavity pressure that affects the injection velocity, which was estimated in terms of a transfer function, \( G_d(z) = (-0.15z^{-1} + a_1z^{-2})/(1 - 0.993z^{-1}) \), where \( a_1 = 0.15 \), by assuming the disturbance magnitude to be less than unity while the disturbance occurred at \( t_0 = 0 \) (Liu et al., 2015). In fact, the disturbance dynamics is time varying while having variable occurrence time from cycle to cycle. It is therefore assumed that \( \sigma(t) = G_d(z) \delta(t - t_0) \), where \( \delta(t) \in [0.005, 0.01] \) for \( t > t_0 \) and \( \delta(t) = 0 \) for \( t < t_0 \). The proposed method using the N4SID (Overschee & Moor, 1994) gives the estimation results on the eigenvalues of the disturbance matrix \( \hat{A} \) listed in Table 1, where the result is shown by the mean value of the estimation accuracy with 100% success ratio, while the bias-eliminated SIM (BESIM) (Liu et al., 2015) with \( p = f = 10 \) and \( q = 7 \) for approximation are also listed in Table 1 for comparison. Scattered plot of the estimated poles are shown in Figure 1.

It is seen that the proposed method gives good estimation accuracy with 100% success ratio, while the recently developed BESIM cannot provide consistent results owing to using the Maclaurin time series for approximation of the load disturbance response, which

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|}
\hline
\text{Method} & \text{\( \hat{\sigma} \)} & \text{\( \sigma \)} & \text{\( r \)} \\
\hline
N4SID & \text{0.15} & \text{0.15} & \text{0} \\
BESIM & \text{0.15} & \text{0.15} & \text{0} \\
\hline
\end{tabular}
\caption{Comparison of estimation results.}
\end{table}
requires \( t_0 = 0 \) for the occurrence of load disturbance. In contrast, the low success ratio resulted from the well-known N4SID may confuse the determination of the true plant model structure in practice.

### 6. Conclusions

A bias-eliminated subspace identification method has been proposed to cope with deterministic type load disturbance with unknown but deterministic dynamics, which can be applied to both open-loop and closed-loop system identification. The output response is decomposed into three parts including deterministic, disturbed and stochastic components in the predictor form, based on the linear superposition principle. Correspondingly, an LQ decomposition approach is established to eliminate the influence from load disturbance and stochastic noise for estimating the deterministic system state. Meanwhile, the disturbance dynamics can also be estimated for reference. The state matrices are retrieved by using a shift-invariant approach. The consistent estimation is clarified with a proof. An illustrative example has well demonstrated the effectiveness and advantage of the proposed method.
