Abstract

We investigate finite energy solutions of Yang–Mills–Chern–Simons systems in odd spacetime dimensions, $d = 2n + 1$, with $n > 2$. This can be carried out systematically for all $n$, but the cases $n = 3, 4$ corresponding to seven- and nine-dimensional spacetimes are treated concretely. These are static and spherically symmetric configurations, defined in a flat Minkowski background. The value of the electric charge is fixed by the Chern–Simons coupling constant.

1. Introduction

Yang–Mills (YM) fields in $d = D + 1$ dimensional spacetime have interesting properties, especially in the static limit where the solutions to the equations of motion describe finite energy topologically stable solutions. Famously, in the case $D = 3$ these are the ’t Hooft–Polyakov monopoles [1, 2] on $\mathbb{R}^3$ whose topological charge is the magnetic flux. In fact, monopoles exist also on all $\mathbb{R}^D$ [3]. Monopoles are supported by Yang–Mills–Higgs (YMH) systems, where the Higgs field (which is always an iso-$D$-vector) defines the topology completely by virtue of the requirement of finiteness of energy [4, 5].

However, in $d = 3 + 1$ dimensional spacetime, there also exists the Julia–Zee (JZ) dyon [6], which in addition to magnetic flux also possesses an electric flux. Unlike the magnetic charge, the electric charge of a dyon, while it is a global charge, is not a topological charge. The topological charge appearing in the JZ dyon is the magnetic monopole charge given by the space-like component $A_i$ of the gauge connection (and the Higgs field $\Phi$), while the electric flux is given by the time-like component $A_0$ (and $\Phi$). By construction, $A_0$ and $\Phi$ are proportional in the absence of a Higgs potential. Now the existence of the JZ dyon is predicated on the presence of a monopole, as well as the availability of the ’t Hooft electromagnetic tensor. This mechanism is restricted to $(3 + 1)$-dimensional spacetime. Although monopoles can be constructed in all dimensions, the definition of a ’t Hooft tensor in higher dimensional space is
problematic, as discussed in [3]. So it is not open to us to exploit the $D$-dimensional monopoles for the purpose of constructing dyons in higher dimensions.

To the best of our knowledge, the only dyon in higher dimensions is the dyonic instanton of Lambert and Tong [14] (LT) in $(4 + 1)$-dimensional spacetime. The topological charge of the LT dyon is the usual instanton number on the $\mathbb{R}^4$ subspace, described by the space-like component $A_i$ of the gauge connection. The electric flux is again given by the time-like component $A_0$ and the Higgs field $\Phi$, as for the JZ dyon. Unlike in the case of the latter however, $A_0$ of the LT dyon is actually equal to $\Phi$ and not just proportional to it. The dyonic instanton describes a global electric flux in addition to the Pontryagin charge (of the second Chern class), the latter being the topological charge analogous to the magnetic charge of the JZ dyon.

Our aim in this work is to construct a new type of instantonic dyons in (higher) odd-dimensional spacetimes. For these solutions, the space-like sector is stabilized by a topological charge, and which supports also an electric flux. As in the case of the LT dyonic instanton, where the ‘magnetic charge’ is the second Chern–Pontryagin (CP) charge, the topological charge here is the $n$th CP charge on $\mathbb{R}^D$, $D = 2n$. The latter is given by the space-like, or ‘magnetic’, component $A_i$ of the gauge connection. Our solutions share this property with the LT dyonic instanton. Naturally, in our case too, the electric flux associated with the solutions proposed is given by the time-like, or ‘electric’, component $A_0$.

The models proposed here differ from those of JZ [6] and of LT [14] in two respects. In common with these, they feature non-Abelian YM fields, but in contrast they contain no Higgs field. The Higgs field is employed to support the magnetic (topological) charge of the JZ dyon, and in the case of the LT dyonic instanton, it supports the component $A_0$. The role corresponding to the Higgs (kinetic) term is here played by the non-Abelian Chern–Simons (CS) density. Employing a CS term in the action for the purpose of supporting $A_0$ is standard, both for Abelian [15, 16] and non-Abelian [17] systems in $2 + 1$ dimensions, as well as in higher dimensions [18].

It is important to emphasize the difference in using the instanton number as the topological charge, rather than the monopole charge. The connection $A_i$ of the instanton behaves asymptotically as a pure-gauge, in contrast to that of monopole which behaves as half-pure-gauge. In other words, the latter is a Dirac–Yang [7–9] monopole decaying as $r^{-1}$, more slowly than the instanton. As a consequence, the energy density functionals of monopoles in higher (than three space-like) dimensions cannot involve the usual quadratic YM term whose energy integral diverges. This is not the case for the faster (pure-gauge) decay of the instanton, which enables the retention of a quadratic YM density in all dimensions, with converging ‘energy integral’. From a physical standpoint, this alone could be considered a motivation for employing instanton numbers in preference to monopole charges as topological charges in higher dimensions.

The models we will introduce will feature the YM sector, consisting of some or all possible terms of the YM hierarchy [11, 12] (to be introduced below), and the CS density in the appropriate dimension. The topological charge is the instanton number of the given YM system on the ‘space-like’ subspace $\mathbb{R}^{15}$ (or $\mathbb{R}^{2n}$), which always includes the usual (quadratic) YM density, as well as at least one other member of the YM hierarchy which is of sufficiently high order in the YM curvature to enable the Derrick scaling requirement for the convergence of the ‘energy integral’ to be satisfied. The application of the Derrick scaling requirement YM sector (on a Euclidean space) is rigorous.

It is important to distinguish the status of the Derrick scaling requirement in the case of dyons where the electric YM connection $A_0$ is introduced in the covariant derivative of the Higgs field as is the case for the JZ and LT dyons, and in our case when it is introduced via a
CS term in the action as was done in the case of the gravitating YMCS system in $4 + 1$ and higher dimensions \cite{18, 19}. (Note also the Abelian \cite{15, 16} and non-Abelian \cite{17} CS–Higgs vortices in $2 + 1$ dimensions, where $A_0$ enters both in the Higgs covariant derivative and the CS density.) The status of Derrick scaling is subtle when there is a CS term in the action, and the non-Abelian case is less transparent than the Abelian. In the Abelian case, the electric gauge connection $A_0$ can be found explicitly by solving the Gauss law equation, and substituting it into the static energy density functional exposes the (Derrick) scaling properties. In the non-Abelian cases \cite{17–19} by contrast, it is not practical to solve the Gauss law equation to yield the (non-Abelian) electric gauge connection $A_0$ explicitly. In those cases, the solution of the Gauss law equation is implicit in the numerical process, resulting nonetheless in the required scaling contribution of the CS term appearing in the action, now in the static energy density. Thus, the CS density acts as a higher order term enabling the Derrick scaling requirement for the finiteness of energy to be satisfied.

Our formulation is in principle for all spacetime dimensions $d = 2n + 1$, $n \geq 3$. We have considered spherically symmetric static solutions, and the asymptotic analysis for these is given for arbitrary $D = 2n$. Explicit, numerical, constructions however are restricted to the $n = 3, 4$ cases.

In section 2, the models are introduced, and the imposition of spherical symmetry as well as the resulting field equations is given in section 3. The solutions are presented in section 4, which includes the asymptotic analysis in the general case, as well as the concrete numerical construction for the dyons in seven- and nine-dimensional spacetimes. In addition, we supply three appendices. Appendix A presents a simplification of the (dynamical) CS density in the static limit. This simplifies the algebraic calculations considerably, in particular enabling the formulation of the arbitrary dimensional case. Appendix B gives the spherically symmetric Ansatz for the full $SO(D + 2)$ YM system. Appendix C gives an attempt at generalizing the LT \cite{14} dyonic instanton in $d = 4 + 1$ to $d = 4p + 1$. While this attempt is not completely satisfactory, the review of that material exposes the essential difference of our instantonic dyons in 7, 9, ... dimensions and the LT dyonic instanton in five dimensions.

2. The models

In selecting the models in $d = D + 1$, with $D = 2n$, we have invoked two criteria, that of the topological stability of the ‘magnetic’ sector, and, that of the existence of a global electric charge. Our first criterion is that the space-like components of the non-Abelian gauge fields describe a topologically stable (static) field configuration characterized by an instanton charge. (The usual action integral here is interpreted as the ‘energy integral’.) For these configurations to have finite energy, it is necessary to employ at least two appropriately scaling members of the YM hierarchy \cite{11, 12, 3} on $\mathbb{R}^D = \mathbb{R}^{2n}:

\begin{equation}
L_{\text{YM}}^{(p)} = \frac{1}{2 \cdot (2p)!} \text{Tr}(F(2p)^2),
\end{equation}

in terms of the ‘magnetic’ field $A_i$. Later, when we introduce the ‘electric’ field $A_0$, this definition will be retained, but then on $d = D + 1$ dimensional spacetime with Minkowskian signature. In (2.1), $F(2p)$ is the totally antisymmetrized $p$-fold product of the YM curvature 2-form $F(2)$. We shall refer to the system (2.1) as a $p$–YM system, with the 1-YM system being the usual YM density. Note that the $p$–YM density scales as $L^{-4p}$. In any given spacetime dimension $d$, the constraint of antisymmetry of $F(2p)$ requires that the highest order curvature term $F(2p_{\text{max}})$ is that with $d = 2p_{\text{max}}$, which scales as $L^{-4p_{\text{max}}}$. 

Subject to this constraint, the most general YM system is the superposition of terms (2.1)

$$L_{YM} = \sum_{p=1}^{p_{\text{max}}} \frac{1}{2 \cdot (2p)!} \text{Tr}[F(2p)^2],$$

(2.2)

with the $p = 1$ term being the usual YM system. Finiteness of the ‘energy’ requires that Derrick scaling be satisfied, and given that the lowest order curvature term with $p = 1$ scales as $L^{-4}$ and the highest with $p = p_{\text{max}}$ as $L^{-2(D+1)}$, this is (more than) sufficient for Derrick scaling to be satisfied on $\mathbb{R}^D$. A subsystem of the superposition (2.2) will be adopted as the YM sector of our models.

Our choice of the YM sector is made such that the solutions on $\mathbb{R}^D$, i.e. the ‘magnetic’ field configurations, have finite ‘energy’ and be topologically stable, as is the case for the $\text{IZ dyon}$ and the dyonic instanton. The topological stability stems from the following sets of inequalities:

$$\text{Tr}[F(2p_1) - (F(2p_2))(2p_1)]^2 \geq 0,$$

(2.3)

where *(F(2p_2)) is the Hodge dual of F(2p_2), which is of course a 2p_1-form, provided that the (p_1, p_2) pair is a partition of 2(p_1 + p_2) = D = 2n. This means that topological stability constrains the highest order curvature term in (2.2), Tr(F(2p_{\text{max}})^2) be the $p_{\text{max}} = D$ term, rather than $p_{\text{max}} = D + 1$ in Minkowski space.

It follows that for any $D = 2n$, one has the ‘energy’ lower bound

$$L_{YM}^{(p_1, p_2)} \overset{\text{def}}{=} \tau_1 L_{YM}^{(p_1)} + \tau_2 L_{YM}^{(p_2)} \geq C_n,$$

(2.4)

for any partition $n = p_1 + p_2$. Here, $C_n$ is the nth CP density, and $(\tau_1, \tau_2)$ are dimensionful (coupling) constants.

The criterion of topological stability (2.4) requires the presence of at least two YM terms. Thus, for simplicity we shall restrict our definitions to systems consisting of exactly two $p$-YM terms. Moreover, for ‘physical’ reasons, we will fix $p_1$ to $p_1 = 1$, so as to retain the usual (quadratic) 1-YM term. This in turn fixes $p_2$ to $p_2 = n - 1$, finally fixing the YM system to the superposition of the 1-YM and the (n − 1)-YM terms:

$$L_{YM} = \tau_1 L_{YM}^{(1)} + \tau_2 L_{YM}^{(n-1)}.$$

(2.5)

Finally, the existence of ‘instantons’ of these systems requires that the YM connection takes its values in the chiral representation of $SO(D) = SO(2n)$, such that the gauge group $G$ must contain the subgroup $SO(D)$. This completes the definition of the YM sector.

Concerning the introduction of the CS term (which fulfils our second criterion, namely that of supporting an electric field), this is uniquely fixed by the dimension $D + 1$ of the spacetime, and is accompanied with the introduction of the ‘electric’ connection $A_0$ to the whole system. The smallest simple gauge group that supports a nonvanishing CS density is $G = SO(D + 2)$, which finally fixes our choice of gauge group. In practice, the gauge group will be truncated to $G = SO(D) \times SO(2)$ because in the spherically symmetric case studied here, it transpires from the asymptotic analysis in section 4 that only $G = SO(D) \times SO(2)$ solutions can be found. (We expect that in the presence of a negative cosmological constant there exist full $SO(D + 2)$ solutions, as was found in [18] for $d = 5$. It is for this reason that the full $SO(D + 2)$ spherically symmetric ansatz is given in appendix B.)

As in all dyonic systems, the topological stability of the purely ‘magnetic’ sector no longer guarantees the existence of finite energy solutions. (Indeed, analytic proofs of existence

---

4 When $p_1 = p_2 = p$, with $D = 4p$, the topological inequalities (2.3) and (2.4) are saturated and there result self-dual BPST [10] configurations [11], with the $p = 1$ case being the usual BPST instanton. We have eschewed this choice here since no solutions exist for such systems when the CS terms are introduced. A discussion of this will be given in section 5.
for dyons are problematic and their existence is usually established numerically, as for the JZ
dyon (in the presence of a Higgs potential), or by explicit construction in a closed form as in
the case of the LT dyonic instanton.)

Therefore the Lagrangians we adopt are

\[ L_{YMCS} = L_{YM} + \kappa L_{CS}^{(n)}, \]

(2.6)
in which \( L_{YM} \) is given by (2.5) and \( L_{CS}^{(n)} \) is the CS density in \( d = 2n + 1 \) dimensional spacetime.

The definition of the CS densities is standard, if complicated, but here we are interested only in static field configurations, in which case it simplifies considerably. The relevant formulas are presented in the appendix, and here we simply state the simplified definition of the static CS densities. With \( \partial_i A_\mu = 0 \), one can show that, up to a total divergence term (which we ignore here since we are only interested in the Euler–Lagrange equations), the effective arbitrary \( n \) CS Lagrangian reduces to the effective density

\[ L_{CS}^{(n)} = (n + 1) \varepsilon_{i_1 i_2 \cdots i_{2n}} \text{Tr}(A_0 F_{i_1 i_2} F_{i_3 i_4} \cdots F_{i_{2n-1} i_{2n}}). \]

(2.7)

To our knowledge, this is a new result, and its derivation is given in appendix A.

Finally, we define the scalar-valued global charges of our solutions. The global charges of a dyon are the magnetic and the electric fluxes. The ‘magnetic’ flux on \( \mathbb{R}^D \) here is the \( n \)th CP charge \( C^{(n)} \), appearing e.g. in (2.4) and (2.3). The definition is familiar in terms of the static ‘magnetic’ curvature \( F_{ij} \).

Next, the definition of the electric flux. As always, the appearance of a CS term in the Lagrangian gives rise to a nontrivial time-like, or ‘electric’, component of the gauge field. The electric flux here

\[ q \simeq \int dS_i E_i \]

(2.8)

\((E_i = F_{i0})\) is a non-Abelian quantity. However, this flux takes its values always in one single element of the \( SO(D + 2) \) algebra, and can therefore be interpreted as the global electric charge. The reason is that at infinity the field is radially symmetric, and subject to spherical symmetry the solutions are restricted to the \( SO(D) \times SO(2) \) subalgebra of \( SO(D + 2) \), and, \( A_0 \) takes its values along the \( SO(2) \) subalgebra. This fact will become clear from the asymptotic analysis below (see (4.3)).

An alternative definition for the electric flux can be given such that it is expressed as a scalar-valued global charge \textit{ab initio}. This is in the same spirit as in [14], the only difference here being that we do not have a Higgs field, instead of which we employ the non-Abelian gauge connection \( A_0 \):

\[ q \overset{\text{def}}{=} \int dS_i \text{Tr}(A_0 E_i) = \int dS_i \text{Tr}(A_0 D_i A_0) = \frac{1}{2} \int dS_i \partial_i \text{Tr} A_0^2 = \frac{1}{2} \int d\Omega_D(D) \frac{d}{dr} \text{Tr} A_0^2, \]

(2.9)

where \( d\Omega_D(D) \) is the angular volume element in \( \mathbb{R}^D \). Both definitions (2.8) and (2.9) give, up to normalization, the same result.

Before proceeding to the consideration of specific models considered, we return to our statement in footnote 4, namely that the choice of the YM sector \( L_{YM} \) in (2.6), given by \( p_1 = p_2 = \frac{D}{2} \) in (2.4), is excluded in this work. There exist no finite energy solutions to those systems, but as seen in the \( D = 4 \) \((n = 2)\) case in five-dimensional spacetime such solutions can be constructed when a suitable scalar field is introduced [20]. Whether such solutions can be constructed in higher dimensional spacetimes with \( n \geqslant 3 \) by the introduction of a scalar field is an open question.
In our concrete numerical constructions, we will consider the following two actions, in $d = 6 + 1$ and $d = 8 + 1$ spacetime dimensions, $n = 3$ and $n = 4$, with $D = 2n$.

\begin{equation}
S_1 = \int_{M} d^{D}x \sqrt{-g} \left[ \frac{\tau_1}{2 \cdot 2!} \text{Tr}[F_{\mu\nu}F^{\mu\nu}] + \frac{\tau_2}{2 \cdot 4!} \text{Tr}[F_{\mu\nu\rho\sigma}F^{\mu\nu\rho\sigma}] \right] + \kappa \int_{M} d^{D}x L^{(3)}_{\text{CS}} \tag{2.10}
\end{equation}

\begin{equation}
S_2 = \int_{M} d^{D}x \sqrt{-g} \left[ \frac{\tau_1}{2 \cdot 2!} \text{Tr}[F_{\mu\nu}F^{\mu\nu}] + \frac{\tau_2}{2 \cdot 6!} \text{Tr}[F_{\mu\nu\rho\sigma\tau\lambda}F^{\mu\nu\rho\sigma\tau\lambda}] \right] + \kappa \int_{M} d^{D}x L^{(4)}_{\text{CS}} \tag{2.11}
\end{equation}

where $F_{\mu\nu} = \partial_{\mu}A_{\nu} - \partial_{\nu}A_{\mu} + [A_{\mu}, A_{\nu}]$ is the gauge field strength tensor, and $\kappa$ is the CS coupling constant.

3. The ansatz and field equations

In appendix B, the static $SO(D + 2)$ YM system on $\mathbb{R}^{D}$ ($D = 2n$) is subjected to spherical symmetry. In this work, we use a particular truncation of this ansatz, namely one where the functions $\phi$ and $\chi$ (which define the magnetic and electric potentials, respectively) are replaced by

\begin{align*}
\tilde{\phi} &= (w, 0, 0) \quad \text{and} \quad \tilde{\chi} = (V, 0, 0).
\end{align*}

This is because subject to spherical symmetry, we could construct only $SO(D) \times SO(2)$ solutions, and not the ones for the full $SO(D + 2)$ gauge group. We have presented the general case in appendix B since we expect that introduction of a negative cosmological constant (i.e., anti-de Sitter spacetime background) would enable the systematic extension of the solution presented here to the full $SO(D + 2)$ case $^5$. The $SO(D) \times SO(2)$ truncated version of the ansatz employed in this work is

\begin{equation}
A = \frac{w(r)}{r} \sum_{i,j} \frac{x^{i}}{r} d^{i} + V(r) \sum_{D+1, D+2} d^{i} \, dt, \quad \text{with} \quad i, j = 1, \ldots, D, \tag{3.1}
\end{equation}

with $\Sigma_{ij}$ being the chiral representation matrices of $SO(D)$, and $\Sigma_{D+1, D+2}$ of the $SO(2)$, subalgebras in $SO(D + 2)$, defined in appendix B. $r$ and $t$ are the radial and time coordinate in the $(D + 1)$-dimensional Minkowski space, while $x^{i}$ are the usual Cartesian coordinates, with $x^{i} x^{i} = r^{2}$. It is convenient to use the following chiral Sigma matrices in $(D + 2)$ dimensions:

\begin{align*}
\Sigma_{i} &= - \tilde{\Sigma}_{i} = i \Gamma_{i}, \quad \Sigma_{D+1} = - \tilde{\Sigma}_{D+1} = i \Gamma_{D+1}, \quad \Sigma_{D+2} = \tilde{\Sigma}_{D+2} = 1 \tag{3.2}
\end{align*}

in terms of the gamma matrices $\Gamma_{M} = (\Gamma_{i}, \Gamma_{m})$ in $(D + 2)$ dimensions.

Subject to the spherical symmetry ansatz (3.1) the $p$–YM ansatz density on $\mathbb{R}^{D}$ reduces to the following one-dimensional functional of $r$:

\begin{align*}
\text{Tr}[F(2p)^{2}] \sqrt{-g} &\simeq \frac{(D - 1)!}{(D - 2p + 1)!} r^{D-p-1} \left( \frac{w^{2} - 1}{r^{2}} \right)^{2(p-1)} \\
&\quad \times \left[ -(2p) V^{2} + (2p - 1)(D - 2p + 1) \\
&\quad \times \left( \frac{w}{r} \right)^{2} + (D - 2p) \left( \frac{w^{2} - 1}{r^{2}} \right)^{2} \right], \tag{3.3}
\end{align*}

where the power of $r^{D-1}$ in the volume element is included.

The corresponding one-dimensional residual density pertaining to (2.7) for arbitrary $D = 2n$ can readily be calculated

\begin{equation}
L^{(n)}_{\text{CS}} = \kappa n (n + 1) V (w^{2} - 1)^{n-1} w'. \tag{3.4}
\end{equation}

$^5$ In [18] (for $D = 4$), the presence of a negative cosmological constant resulted in the full $SO(D + 2)$ solutions being realized for the gravitating YMCS system.
Substituting this ansatz in (2.6), we find the one-dimensional reduced Lagrangian
\[ S_{\text{eff}} = \int dt dr \left[ r^{D-1} \left( -\frac{1}{2} V'^2 + (D-1) \left( \frac{w'^2}{2r^2} + \frac{(D-2)(1-w^2)^2}{4r^4} \right) \right) + \frac{\tau}{2(2p-1)!} r^{D-1} \left( 1 - \frac{w^2}{r^2} \right)^{2(p-1)} \left( - V'^2 + (2p-1)(D-2p+1) \right. \right. \]
\[ \times \left. \left( \frac{w'^2}{r^2} + \frac{(D-2p)(1-w^2)^2}{2pr^4} \right) \right) - \kappa D(D+2)V(w^2 - 1)^{\frac{1}{2}}(D-2)w' \right]. \]
(3.5)

where a prime denotes a derivative with respect to \( r \). Here we have scaled out the factor \( \tau_1 \) (rescaling \( \kappa \) accordingly) and denoted \( \tau = \tau_2 \frac{D+2}{(2p-1)!} ; \) also to simplify the relations we have denoted \( p_2 = p \) henceforth.

The corresponding energy of the solutions is given by the integral
\[ E = V_{D-1} \int_0^\infty dr \left[ r^{D-1} \left( \frac{1}{2} V'^2 + (D-1) \left( \frac{w'^2}{2r^2} + \frac{(D-2)(1-w^2)^2}{4r^4} \right) \right) + \frac{\tau}{2(2p-1)!} r^{D-1} \left( 1 - \frac{w^2}{r^2} \right)^{2(p-1)} \right. \]
\[ \times \left. \left( V'^2 + (2p-1)(D-2p+1) \left( \frac{w'^2}{r^2} + \frac{(D-2p)(1-w^2)^2}{2pr^4} \right) \right) \right] . \]
(3.6)

The resulting (ordinary differential) equations are
\[ w'' \left( 1 + \frac{\tau}{(2p-1)!} \right) \frac{1}{(D-2p+1)} \left( 1 - \frac{w^2}{r^2} \right)^{2(p-1)} + \frac{(D-3)w'}{r} - \frac{(D-2)w(w^2 - 1)}{r^2} \]
\[ - \frac{D(D+2)\kappa}{r^{D-3}(D-1)} \frac{dF(w)}{dw} + \frac{\tau}{(2p-1)!} \frac{2(p-1)}{D-1} \left( 1 - \frac{w^2 - 1}{r^2} \right)^{2p-3} \]
\[ \times \left( wV'^2 + \frac{(2p-1)(D-2p+1)}{2(p-1)r^2} (rw' (D-4p+1) (w^2 - 1)) \right. \]
\[ + 2(p-1)rw'w') - (D-2p)w(1-w^2)^2 \right) = 0 , \]
(3.7)

and
\[ \left[ r^{D-1}w' \left( 1 + \frac{\tau}{(2p-1)!} \right) \left( 1 - \frac{w^2}{r^2} \right)^{2(p-1)} \right] - \kappa D(D+2)F(w) \right] = 0 , \]
(3.8)

the last one being the Gauss law equation. The function \( F(w) \) in (3.7)–(3.8) has the following general expression in terms of the hypergeometric function \( \_2F_1 \):
\[ F(w) = - (-1)^{\frac{D}{2}} \_2F_1 \left( \frac{1}{2}, \frac{D}{2}; \frac{3}{2}; w^2 \right) / w . \]
(3.9)

As seen from relation (3.8), an important generic feature of YMCS models within the \( SO(D) \times SO(2) \) truncation is the existence of the first integral for the electric potential \( V(r) \),
\[ V' + \frac{1}{r^{D-1}} \frac{P - \kappa D(D+2)}{1 + \frac{(2p-1)!}{(2p-1)!} \left( \frac{w^2 - 1}{r^2} \right)^{2(p-1)}} F(w) = 0 , \]
(3.10)

with \( P \) an integration constant, which, as we shall see, for regular solutions is fixed by \( \kappa \).

One can note that equations (3.7) and (3.10) are invariant under the scaling
\[ r \rightarrow \lambda r, \ w \rightarrow w, \ V \rightarrow V / \lambda, \ \tau \rightarrow \lambda^{D-1} \tau, \ \text{and} \ \kappa \rightarrow \lambda^{D-4} \kappa , \]
(3.11)
with \( \lambda \) being an arbitrary positive parameter. Then, without any loss of generality one can set in this way \( \tau \) or \( \kappa \) to take an arbitrary nonzero value.

Another symmetry of the equations of the model (3.7), (3.8) consists in simultaneously changing the sign of the CS coupling constant together with the electric or magnetic potential

\[
\kappa \to -\kappa, \quad V \to -V, \quad \text{or} \quad \kappa \to -\kappa, \quad w \to -w.
\]

(3.12)

In what follows, we shall use this symmetry to study solutions with a positive \( \kappa \) only.

4. The solutions

We start by presenting the expansion of the solutions at near the origin \( r = 0 \). The regularity of the gauge field implies \( w \to \pm 1 \) there. Then it follows that the parameter \( P \) in the first integral (3.10) is fixed by the value of the CS coupling constant. Technically, this results from the fact that the term \( P - \kappa D(D + 2)F(\pm 1) \) should vanish as \( r \to 0 \). Restricting oneself without any loss of generality to \( w(0) = 1 \), one finds

\[
P = \kappa D(D + 2)F(1).
\]

(4.1)

Then one finds the following expansions near the origin:

\[
w(r) = 1 - br^2 + O(r^4), \quad V(r) = \kappa \left( -2 \right) \frac{b}{\sqrt{2\pi}} \frac{b}{\Gamma(2p + 1)} r^2 + O(r^6).
\]

(4.2)

The only free parameters here is \( b = -\frac{1}{2} w''(0) \). The coefficients of all higher order terms in the \( r \to 0 \) expansion are fixed by \( b \).

The solutions have the following expansion\(^6\) as \( r \to \infty \):

\[
w(r) = -1 - \frac{J}{r^{D-2}} + O(1/r^D), \quad V(r) = V_0 - \left( \frac{Q}{r^{D-2}} + O(1/r^D) \right).
\]

(4.3)

In the above relations, \( J \) and \( V_0 \) are the parameters given by numerics which fix all higher order terms, while \( Q \) is a constant fixing the electric charge of the solutions,

\[
Q = \kappa \left( -1 \right)^{\frac{D}{2}} \sqrt{\pi} \frac{D(D + 2)}{D - 2} \frac{\Gamma\left( \frac{D}{2} \right)}{\Gamma\left( \frac{D-1}{2} \right)}.
\]

(4.4)

The solutions interpolating between the asymptotics (4.2) and (4.3) were constructed by using a standard Runge–Kutta ordinary differential equation solver. In this approach, we evaluate the initial conditions at \( r = 10^{-5} \), for global tolerance \( 10^{-12} \), adjusting for shooting parameters and integrating toward \( r \to \infty \). The input parameters are \( \tau \) and \( \kappa \). (Note that only the ratio of these two constants is relevant.)

Our numerical analysis gives evidence for the existence of nontrivial solutions of equations (3.7) and (3.8) for \( D = 6, 8 \), with these cases being studied in a systematic way. However, solutions with similar properties should exist for all higher values of \( D = 2n \). The profile of a typical solution for the case \( D = 6, p = 2 \) is given in figure 1. For all solutions we have constructed, the gauge function \( w(r) \) has a monotonic behavior, with a single node for an intermediate value of \( r \). A monotonic behavior has been also noted for the electric potential \( V(r) \). For moderate values of the ratio \( \tau \kappa \), the energy density is mainly concentrated in a shell, its maximum corresponding to the position of the node of the magnetic gauge function.

The dependence of solutions on the parameters \( \kappa, \tau \) is shown in figure 2. Starting with the dependence on the parameter \( \kappa \), we note that nontrivial solutions with finite mass are also found in the absence of a CS term, \( \kappa = 0 \). However, these configurations have a vanishing

---

\(^6\) Note that although \( w(\infty) = 1 \) is also allowed, we could not find such multinode solutions.
electric potential and correspond to the instantons in [13]. The total mass of solutions increases almost linearly with $\kappa$, while the shooting parameter $b = -\frac{1}{2}w''(0)$ decreases. Also, as one can see in figure 2 (right), one can find finite energy solutions of the YMCS equations even in the absence of the $\mathcal{L}_n^{(n-1)}$ term in (2.5), i.e. for $\tau_2 = 0$.

5. Summary and discussion

We have formulated the construction of dyon solutions to a family of Yang–Mills–Chern–Simons systems in $(2n + 1)$-dimensional ($n \geq 3$) flat spacetime. These are static spherically symmetric field configurations carrying both magnetic and electric fluxes. The components of the non-Abelian gauge connection $A_\mu = (A_i, A_0)$ are defined to be in the algebra of $SO(D+2)$, but subject to spherically symmetry the solutions turn out to take their values in the subalgebra $SO(D) \times SO(2)$.

Just as for the other known dyonic solutions in four-dimensional [6] and five-dimensional [14] spacetimes, the ‘magnetic’ flux is a topological charge. In four dimensions the topological charge of the Julia–Zee (JZ) dyon is the monopole charge on $\mathbb{R}^3$, which is a descendant [3] of the second Chern–Pontryagin (CP) charge. In five dimensions, the topological charge of the Lambert–Tong (LT) dyonic instanton, it is the second CP charge itself on $\mathbb{R}^4$. In our case
here, the topological charge is the \( n \)th CP charge on \( \mathbb{R}^n \), \( n \geq 3 \). In the above, we have referred to the topological charges as ‘magnetic’ charges, in analogy with [6], and also because these are defined exclusively in terms of the static space-like (or ‘magnetic’) components of the connection \( A_i \), with the time-like (or ‘electric’) components \( A_0 \) entering the definition of the ‘electric’ flux.

In this context, the JZ dyon can be described as a monopolic dyon\(^7\), while the LT dyon and our solutions can be described as an instantonic dyons. The salient difference between the two types of topological charge is that the former decay like Dirac–Yang [9] monopoles and hence in all but \( 3 + 1 \) dimensions the energy integral of the usual (quadratic) Yang–Mills (YM) term diverges, while the latter decay (like instantons) faster and the ‘energy’ integral of the usual YM term converges. This can be seen as a desirable ‘physical’ feature.

Concerning the detailed choice of the models proposed, the gauge field system supporting the topological (magnetic) charge is directly specified like in the known dyonic models. In the case of the JZ dyon, this is the usual \( SU(2) \) Georgi–Glashow model \(^8\). In the case of the LT dyon, this is the usual (quadratic) \( SO_4(4) = SU_{LR}(2) \) YM model. In our case, like LT, the sector supporting the topological charge is described by the non-Abelian gauge field only, and the natural system is then the superposition of members of the YM hierarchy (2.2). Now the number of terms in (2.2) grows with increasing \( D \) (or \( n \)) and it may be reasonable to retain the minimum number of these necessary for the Derrick scaling requirement to be satisfied. For this, one can select any pair of terms, both with even \( p \), for which the topological inequality (2.3) can be satisfied. Of such pairs, it may be reasonable to privilege the pair \( p_1 = 1, \ p_2 = n - 1 \), if only for ‘physical’ reasons favoring the presence of the usual (quadratic) YM term. This is not necessary, but it is what we have done and as it happens in the two examples in seven and nine dimensions studied quantitatively, these are the unique possibilities.

Alternatively, one might have opted to retain only the \( p = \frac{D}{4} \) term in (2.2), i.e. with \( \tau_1 = 0 \) in (2.5), which on its own satisfies the Derrick scaling requirement. (See footnote 4.) After the introduction of the CS term (and of \( A_0 \)), however, such solutions were not found. This is because the appearance of the CS term in the action results in the effective presence of a higher order term in the static energy density functional, as explained in section 1. This effective higher order CS term, which scales as \( L^{-1} \), then destroys the previous Derrick scaling balance. This is why we have proposed models in \( d = 2n + 1 \) for \( n \geq 3 \) only, since in \( d = 5 \) the only choice for the (magnetic) YM sector is the \( p = 1 \) YM term. How this obstacle is circumvented in the case of the LT dyonic instanton [14] (and all higher analogues in \( d = 4p + 1 \) dimensional spacetime) can be seen in appendix C.

As a final comment, we note that the solutions discussed here are exclusively spherically symmetric. One would expect that there exist dyons of these systems subject to less stringent symmetries, though technically the numerical construction of these putative dyons would be a formidable task.

Acknowledgments

We thank Neil Lambert, David Tong and Yisong Yang for discussions on dyons of non-Abelian Yang–Mills–Chern–Simons systems, and Jurgen Burzlaff for helpful comments. This work is

\(^7\) Configurations carrying non-Abelian ‘electric’ fields in all dimensions can be readily constructed by riding on the back of monopoles on \( \mathbb{R}^D \). But the existence of a scalar-valued global electric flux relies on the definition of a ‘t Hooft electromagnetic, something that is problematic in flat spacetime dimensions higher than 4.

\(^8\) Although in that case one can employ instead any one of the excited Georgi–Glashow models, or any superposition thereof, which descend from higher than 4 dimensions [3].

**Appendix A. Static limit of the Chern–Simons density in 2n + 1 dimensions**

To illustrate our statement, namely the result (2.7), we carry out the relevant computations explicitly in three-, five- and seven-dimensional spacetimes. The CS densities \( \Omega^{(2n+1)}_{CS} \) in question, for \( n = 1, 2 \) and 3, are

\[
\begin{align*}
\Omega^{(3)}_{CS} &= \varepsilon_{\mu\nu\rho} \text{Tr} \{ A_i [F_{\mu\nu} - \frac{2}{3} A_{\mu} A_{\nu}] \}, \\
\Omega^{(5)}_{CS} &= \varepsilon_{\mu\nu\rho\sigma\tau} \text{Tr} \{ A_i [F_{\mu\nu} F_{\rho\sigma} - F_{\mu\rho} A_{\nu} A_{\sigma} + \frac{2}{5} A_{\mu} A_{\nu} A_{\rho} A_{\sigma}] \}, \\
\Omega^{(7)}_{CS} &= \varepsilon_{\mu\nu\rho\sigma\tau\kappa} \text{Tr} \{ A_i [F_{\mu\nu} F_{\rho\sigma} F_{\tau\kappa} - \frac{4}{7} F_{\mu\nu} F_{\rho\sigma} A_{\tau} A_{\kappa} - \frac{2}{5} F_{\mu\nu} A_{\rho} F_{\sigma\tau} A_{\kappa} \\
&\quad + \frac{2}{7} F_{\mu\nu} A_{\rho} A_{\sigma} A_{\tau} A_{\kappa} - \frac{8}{35} A_{\mu} A_{\nu} A_{\rho} A_{\sigma} A_{\tau} A_{\kappa}] \},
\end{align*}
\tag{A.1}
\]

which are by construction gauge variant. Their variations however are by contrast gauge covariant and are easily expressed in the general 2n + 1 case as

\[
\delta A_i \Omega^{(2n+1)}_{CS} = (n + 1) \varepsilon^{\mu\nu\rho\sigma\tau\kappa} F_{\mu\nu} F_{\rho\sigma} F_{\tau\kappa} \cdot F_{A_i} + \cdots + F_{A_1} F_{A_2} \cdots F_{A_{2n-1}} F_{A_{2n}}.
\tag{A.2}
\]

The statement here is the following: for static fields, the CS density \( \Omega^{(2n+1)}_{CS} \) on \( d = 2n + 1 \) dimensional spacetime reduces to (3.4), namely to

\[
\Omega^{(2n+1)}_{CS} = \nabla \cdot \Omega^{(2n+1)} + (n + 1) \text{Tr} [ A_0 F \wedge F \wedge \cdots \wedge F ], \quad n \text{ times.}
\tag{A.3}
\]

To illustrate this, we give the explicit total divergence expressions for \( n = 1, 2 \) and 3 (A.3) are

\[
\begin{align*}
\Omega^{(3)}_{CS} &= 2 \varepsilon_{ij} \text{Tr} [ A_0 F_{ij} ] + \nabla \cdot \Omega^{(3)} \\
\Omega^{(5)}_{CS} &= 3 \varepsilon_{ijkl} \text{Tr} [ A_0 F_{ijkl} ] + \nabla \cdot \Omega^{(5)} \\
\Omega^{(7)}_{CS} &= 4 \varepsilon_{ijklmn} \text{Tr} [ A_0 F_{ijkl} F_{mn} ] + \nabla \cdot \Omega^{(7)},
\end{align*}
\tag{A.4}
\]

with \( \Omega^{(2n+1)} \equiv \Omega^{(2n+1)}_{CS} \) given by

\[
\begin{align*}
\Omega^{(3)}_i &= -2 \varepsilon_{ij} \text{Tr} [ A_0 A_j ], \\
\Omega^{(5)}_i &= -2 \varepsilon_{ijkl} \text{Tr} [ A_0 ( A_j F_{ik} + F_{ik} A_j ) - A_k A_l A_j ], \\
\Omega^{(7)}_i &= -2 \varepsilon_{ijklm} \text{Tr} [ A_0 \left( (F_{ik} F_{jm} A_n + A_n F_{ik} F_{jm} + A_{ij} F_{kl} F_{mn} ) - \frac{4}{7} (A_k A_l A_n F_{ij} + F_{ij} A_k A_l A_n) \\
&\quad + \frac{2}{7} (A_k A_l F_{ij} A_n + A_n F_{ij} A_k A_l) + \frac{2}{5} A_l A_k A_j A_0 A_n ) \right] ].
\end{align*}
\tag{A.5}
\]

**Appendix B. Spherically symmetric ansatz for SO(D + 2) YM on \( \mathbb{R}^D \)**

The static spherical symmetric ansatz for the SO(6) Yang–Mills (YM) system on \( \mathbb{R}^6 \), used in [18], is extended to the SO(D + 2) YM on \( \mathbb{R}^D \), i.e. in \( (D + 1) \)-dimensional spacetime with \( D = 2n \). Since \( D \) is even, we can take the YM connection to take its values in one or other chiral representation of \( SO(2, D + 2) \), such that our spherically symmetric ansatz is expressed in terms of the representation matrices

\[
\Sigma^{(+)}_{\alpha\beta} = -\frac{1}{4} \left( \frac{1 \pm \Gamma_{2n+3}}{2} \right) [\Gamma_{\alpha}, \Gamma_{\beta}], \quad \alpha, \beta = 1, 2, \ldots, 2n + 2,
\tag{B.1}
\]

\( \Gamma_{\alpha} = (\Gamma_{\alpha}, \Gamma_{\alpha}) \), with the index \( M = (2n + 1, 2n + 2) \), being the gamma matrices in \( 2n + 2 \) dimensions and \( \Gamma_{2n+3} \), the corresponding chiral matrix.
Our spherically symmetric ansatz for the YM connection $A_{\mu} = (A_0, A_i)$ is
\begin{equation}
A_0 = - (\varepsilon \chi)^M \hat{x}_j \Sigma^{(\pm)}_{jm} - \chi^{2n+3} \Sigma^{(\pm)}_{2n+1,2n+2} \tag{B.2}
\end{equation}

\begin{equation}
A_i = \left( \frac{\phi^{2n+3} + 1}{r} \right) \Sigma^{(\pm)}_{ij} \hat{x}_j + \left( \frac{\phi^M}{r} \right) \left( \delta_{ij} - \hat{x}_i \hat{x}_j \right) + (\varepsilon A_i)^M \hat{x}_i \hat{x}_j \right) \Sigma^{(\pm)}_{jm} + A^M_{2n+3} \chi \Sigma^{(\pm)}_{2n+1,2n+2} \tag{B.3}
\end{equation}

in which the summed over indices $M, N = 2n + 1, 2n + 2$ run over two values such that we can label the functions $(\phi^M, \phi^{2n+3}) \equiv \tilde{\phi}$, $(\chi^M, \chi^{2n+3}) \equiv \tilde{\chi}$ and $(A^M_i, A^M_{2n+3}) \equiv \tilde{A}_i$ like three isotriplets $\tilde{\phi}, \tilde{\chi}$ and $\tilde{A}_i$, all depending on the $2n$-dimensional space-like radial variable $r$. $\varepsilon$ is the two-dimensional Lévi-Civitá symbol.

The parametrization used in the ansatz (B.2)–(B.3) results in a gauge covariant expression for the YM curvature $F_{\mu\nu} = (F_{ij}, F_{0i})$:
\begin{equation}
F_{ij} = \frac{1}{r} \left( (|\tilde{\phi}|^2 - 1) \right) \Sigma^{(\pm)}_{ij} + \frac{1}{r} \left( D_r \phi^{2n+3} + \frac{1}{r} (|\tilde{\phi}|^2 - 1) \right) \hat{x}_i \Sigma^{(\pm)}_{jk} \hat{x}_k + \frac{1}{r} D_r \phi^M \chi \Sigma^{(\pm)}_{jm} \tag{B.4}
\end{equation}

\begin{equation}
F_{0i} = - \frac{1}{r} \phi^M (\varepsilon \chi)^M \Sigma^{(\pm)}_{ij} \hat{x}_j + \frac{1}{r} \left( \phi^{2n+3} (\varepsilon \chi)^M - \chi^{2n+3} (\varepsilon \phi)^M \right) \Sigma^{(\pm)}_{jm} \tag{B.5}
\end{equation}

in which we have used the notation
\begin{equation}
D_r \phi^a = \partial_r \phi^a + \varepsilon^{abc} A^b_r \phi^c, \quad D_r \chi^a = \partial_r \chi^a + \varepsilon^{abc} A^b_r \chi^c \tag{B.6}
\end{equation}
as the $SO(3)$ covariant derivatives of the two triplets $\tilde{\phi} \equiv \phi^a$, $\tilde{\chi} \equiv \chi^a$, with respect to the $SO(3)$ gauge connection $\tilde{A}_i \equiv A^i$. This gauge connection (in one dimension, $r$) is of course trivial and hence does not appear in the field equations, but it serves to give the constraint equation.

Appendix C. Dyonic instantons in $d = 4p + 1$ dimensional spacetimes

The dyonic instanton is a (static) solution to the Yang–Mills–Higgs model in $4 + 1$ dimensions. It shares with the IZ dyon, the presence of a Higgs term in the action, which is to be identified with the electric non-Abelian connection $A_0$ leading to the definition of the electric flux. This is in direct contrast with the models proposed here, which feature no Higgs field and $A_0$ appears through the CP terms in the action.

In contrast to the IZ dyon, however, static energy density functional of the Lambert–Tong (LT) dyonic instanton does not depend on the Higgs field and consists solely of the usual YM action density. More specifically, the YM field is the (anti-)self-dual instanton on $\mathbb{R}^4$. As such the Higgs field plays an auxiliary role in the description of the LT dyonic instanton, and is needed only for the definition of the global electric flux. This makes it possible to generalize the construction of dyonic instantons to $(4p + 1)$-dimensional spacetimes, albeit in a rather limited context. This is our aim in this appendix.

We limit our considerations here to the recovery of the $(4 + 1)$-dimensional LT dyonic instanton, and proceed to its $(8 + 1)$-dimensional version. The $(4p + 1)$-dimensional case then follows systematically. The Lagrangian $L_{D+1}$ for $D = 4$ is
\begin{equation}
L_{4+1} = - \frac{1}{2} \frac{1}{2!} \text{Tr}[F_{ij}F^{ij}] + \frac{1}{2} \text{Tr}[D_r \Phi D^r \Phi], \tag{C.1}
\end{equation}
yielding the following gauge field equations:
\begin{align}
D_\mu F_{\mu 0} - [\Phi, D_0 \Phi] &= 0 \\
D_\mu F_{\mu \nu} - D_0 F_{0 \nu} - [\Phi, D_\nu \Phi] &= 0,
\end{align}
and the Higgs field equation
\[ D_0^2 \Phi - D_\mu^2 \Phi = 0 \]

having used the Minkowskian metric \( \eta_{ij} = \text{diag}(+, -, -, -) \), with \( \eta_{00} = 1 \) and \( \eta_{\mu \nu} = -\delta_{\mu \nu}, \ i = 0, \mu \).

Equation (C.2) is the Gauss law equation, and (C.3) the Ampere equations. The Hamiltonian is
\begin{align}
H_{4+1} &= \frac{1}{4} \text{Tr} \left\{ \frac{1}{2} F_{\mu \nu}^2 + F_{0 \nu}^2 + D_\nu \Phi^2 + D_0 \Phi^2 \right\} \\
&= \frac{1}{4} \text{Tr} \left\{ \frac{1}{2} F_{\mu \nu}^2 + (F_{0 \mu} - D_\mu \Phi)^2 + D_\nu \Phi^2 + 2 D_\mu \Phi F_{0 \mu} \right\}.
\end{align}

Following [14], we have expressed the second line of (C.6) such that after substituting the Gauss law equation (C.2) and discarding the surface term arising from
\[ \partial_\mu \text{Tr} \left\{ \Phi F_{0 \mu} \right\}, \]
(C.6) takes the form
\[ H_{4+1} = \frac{1}{4} \text{Tr} \left\{ \frac{1}{2} F_{\mu \nu}^2 + (F_{0 \mu} - D_\mu \Phi)^2 + D_\nu \Phi^2 \right\}. \]

We now restrict our attention to static solutions and choose
\[ A_0 = \Phi \Rightarrow D_0 \Phi = 0, \quad F_{0 \mu} = D_\mu \Phi, \]
(C.8)
as a result of which the static limit of the Hamiltonian (C.7) just reduces to the action density of the 1-YM system, i.e. only the first term in (C.7), whose action is minimized absolutely by the 1-BPST solution [10].

Using (C.8), one can readily verify that the Ampere law equation (C.3) reduces to
\[ D_\mu F_{\mu \nu} = 0 \]
which is solved by the self-dual BPST fields, and the Gauss law equation (C.2) and Higgs equation (C.4) become identical, reducing to
\[ D_\mu D_\mu \Phi = 0. \]

There remains to find a regular solution to (C.9), which we delay till after treating the \((8 + 1)\)-dimensional case, next.

The Lagrangian \( \mathcal{L}_{D+1} \) in the \( D = 8 \) case is
\[ \mathcal{L}_{8+1} = -\frac{1}{2 \cdot 4!} \text{Tr}[F_{ijkl} F^{ijkl}] + \frac{1}{2 \cdot 3!} \text{Tr}[F_{ijk} F^{ijk}] \]
(C.10)
in which we have used the notation
\begin{align}
F_{ijkl} &= \{ F_{ij}, F_{kl} \} = \{ F_{ij}, F_{kl} \} + \{ F_{ik}, F_{lj} \} + \{ F_{il}, F_{kj} \} \\
F_{ijk} &= \{ F_{ij}, D_k \Phi \} = \{ F_{ij}, D_k \Phi \} + \{ F_{ik}, D_j \Phi \} + \{ F_{il}, D_j \Phi \}. \quad (C.11) \end{align}

The choice of the Higgs kinetic term \( \text{Tr}[F_{ijkl} D_k \Phi]^2 \) here, instead of the usual one \( \text{Tr} D_\mu \Phi^2 \), is made so that the static Euler–Lagrange equation for \( A_0 = \Phi \) becomes identical to the corresponding Higgs equation after the identification \( A_0 = \Phi \) is made.
Using the same Minkowskian metric as above (but in $8 + 1$ dimensions now) we have the following Yang–Mills equations:

\[
D_\mu [F_{\rho\sigma}, F_{\mu\nu\rho\sigma}] + 2D_\mu [D_\rho \Phi, F_{\mu\nu\rho}] + [\Phi, [F_{\rho\sigma}, F_{\mu\nu\rho\sigma}]] = 0 \tag{C.13}
\]

\[
D_\mu [F_{\rho\sigma}, F_{\mu\nu\rho\sigma}] + 2D_\mu [D_\rho \Phi, F_{\mu\nu\rho}] - 2D_\mu (D_\rho \Phi, F_{0\mu\nu\rho}) - D_\mu [D_\rho \Phi, F_{0\mu\nu\rho}] = 0
\]

\[
- D_\rho [D_\sigma \Phi, F_{\nu\rho}] - 2[D_\rho, [F_{\rho\sigma}, F_{\nu\rho}]] = 0 \tag{C.14}
\]

and the Higgs equation

\[
D_\mu [F_{\rho\sigma}, F_{\mu\nu\rho\sigma}] + 2D_\mu [F_{0\mu}, F_{0\mu\nu\sigma}] - D_\rho [F_{0\mu\nu}, F_{0\mu\nu\sigma}] = 0. \tag{C.15}
\]

Equation (C.13) is the Gauss law equation and (C.14) is the Ampere equation.

The Hamiltonian of (C.10) is

\[
\mathcal{H}_{8+1} = \frac{1}{4!} \text{Tr} \left( \frac{1}{4} F_{\mu\nu\rho\sigma}^2 + F_{0\mu\nu\rho}^2 + F_{\mu\nu}^2 + 2 F_{0\mu\nu}^2 \right) \tag{C.16}
\]

\[
= \frac{1}{4!} \text{Tr} \left( \frac{1}{4} F_{\mu\nu\rho\sigma}^2 + (F_{0\mu\nu\rho} - F_{\mu\nu\rho})^2 + 2 F_{0\mu\nu}^2 + 2 F_{0\mu\nu\sigma} F_{\sigma\mu\nu} \right) \tag{C.17}
\]

where again, as in the $D = 4$ case above, we have expressed the second line of (C.17) such that after substituting the Gauss law equation (C.13) and discarding the surface term arising from

\[
\partial_\nu \text{Tr} \Phi [F_{\mu\nu}, F_{\mu\nu\sigma}]
\]

(C.17) takes the form

\[
\mathcal{H}_{8+1} = \frac{1}{4!} \text{Tr} \left[ \frac{1}{4} F_{\mu\nu\rho\sigma}^2 + (F_{0\mu\nu\rho} - F_{\mu\nu\rho})^2 + 2 F_{0\mu\nu}^2 + 12 \Phi D_\mu [D_\nu \Phi, F_{0\mu\nu}] \right]. \tag{C.18}
\]

Again, we restrict our attention to static solutions, and as in the $p = 1$ case above we choose

\[
A_0 = \Phi \Rightarrow D_0 \Phi = 0, \quad F_{0\mu} = D_\mu \Phi, \quad F_{\mu\nu} = F_{0\mu\nu}, \quad F_{0\mu\nu} = 0, \tag{C.19}
\]

as a result of which the static limit of the Hamiltonian (C.18) just reduces to the action density of the 2–YM system, i.e. only the first term in (C.18), whose action is minimized absolutely by the 2-BPST solution [11].

Using (C.19), one can readily verify that the Ampere equation (C.14) reduces to

\[
D_\mu [F_{\rho\sigma}, F_{\mu\nu\rho\sigma}] = 0
\]

which is solved by the self-dual $p = 2$ BPST fields, and the Gauss law equation (C.13) and Higgs equation (C.15) become identical, reducing to

\[
D_\mu [F_{\rho\sigma}, [F_{\rho\sigma}, D_\mu \Phi]] = 0. \tag{C.20}
\]

Up to this point, the $D = 4$ and the $D = 8$ cases are on the same footing, and hence also is the generic $D = 4p$ case. The remaining task in all these cases is the construction of a regular solution to the Higgs equations (C.9) and (C.20), etc, such that the magnitude of the Higgs field tends to a constant at infinity. This is to guarantee the convergence of the surface integral

\[
g \simeq \int_{S_{d-1}} \text{Tr} [\Phi F_{\mu\nu}] dS^\alpha, \tag{C.21}
\]

for the electric flux. The integral (C.21) will be convergent provided that the Higgs field $\Phi = A_0$ decays fast enough at infinity and is regular at the origin. Such a solution was found [14] for $D = 4$ ($p = 1$) but unfortunately, we have not succeeded to do this for the new, $p \geq 2$ cases. Let us discuss this question a little further.
In the $D = 4$ ($p = 1$) case, the Higgs equation (C.9) is solved most conveniently in the background of the BPST field in the 't Hooft singular gauge

$$A^{(s)}_{\mu} = \frac{1 - w(r)}{r} \Sigma_{\mu \nu} \hat{k}_{\nu}, \quad w(r) = -\frac{\lambda^2 - r^2}{\lambda^2 + r^2},$$  \hspace{1cm} (C.22)

by positing the following ansatz for the Higgs field:

$$\Phi = h(r) \Sigma_{54},$$  \hspace{1cm} (C.23)

and noting\(^9\) that the inverse of the function multiplying $\Sigma_{\mu \nu}$ in (C.22), namely that

$$h(r) = \frac{r}{1 - w(r)}$$  \hspace{1cm} (C.24)

solves (C.9). (In (C.22) and (C.23), $\Sigma_{\mu \nu}$ are the chiral representations of the algebra of $SO(4)$.)

Solving (C.20) in the background of (C.22) (now interpreting $\Sigma_{\mu \nu}$ there as the chiral representations of the algebra of $SO(8)$) is a very difficult task, which we have not succeeded in. Even finding an ansatz like (C.24) for $\Phi$, which yields a single ordinary differential equation (ODE) for $h(r)$ is problematic.

Recognizing that the Higgs field (or $A_0^\nu$) does not necessarily have to take its values inside the algebra of the ‘magnetic’ field, we found an ansatz for the Higgs field that leads to a single ODE. This is

$$\Phi = h(r) \Sigma_{5678}, \quad \Sigma_{5678} = \{\Sigma_{56}, \Sigma_{78}\} \equiv \{\Sigma_{58}, \Sigma_{78}\} + \text{cycl.} \quad (678),$$  \hspace{1cm} (C.25)

for which equation (C.20) reduces to one single ODE for the function $h(r)$. This is

$$-16\lambda^2 (3\lambda^2 + 2r^2)h + 3r(\lambda^2 + r^2) (7\lambda^2 - r^2)h' + r(\lambda^2 + r^2) h'' = 0.$$  \hspace{1cm} (C.26)

The asymptotic solutions of (C.26) are found. As $r \to 0$, $h(r)$ behaves as

$$h(r) = g_2 r^2 - \frac{2g_2}{9 \lambda^2} r^4 + \frac{4g_2}{27 \lambda^2} r^6 + O(r^8)$$  \hspace{1cm} (C.27)

(with a free parameter $g_2$), while it decays at infinity as

$$h(r) = g_0 + \frac{4g_0}{3r^2} + \frac{34g_0 \lambda^4}{27 r^4} + O(1/r^6),$$  \hspace{1cm} (C.28)

with $g_0$ being another free parameter.

Unfortunately, there exist no solutions $h$ of (C.26) that satisfy the two asymptotic values in (C.27) and (C.28), simultaneously. This can be seen simply as follows. Let $g_0 > 0$; then according to (C.28) $h' < 0$ at large $r$. But we know from (C.27) that $h(0) = 0$, so at some finite value of $r = r_0$, the function $h$ must have a maximum $h(r_0) = h_{\text{max}}$, with $h_{\text{max}} > 0$. Also, $h'(r_0) = 0$ and $h''(r_0) < 0$. Substituting $h(r_0) = h_{\text{max}} > 0$, $h'(r_0) = 0$ and $h''(r_0) = -\mu^2$ in (C.26) results in a contradiction. (This argument can be reversed starting with $g_0 < 0$.)

So even with the special ansatz (C.25), there exist no solutions supporting a nontrivial Higgs field for the $p = 2$ case presented above. Since the Higgs field is necessary for the definition of a (finite) global electric charge, this means that we cannot find a natural generalization of the LT dyonic instantons in $d = 4p + 1 > 5$ dimensional Minkowski space.
