A B S T R A C T

The molecular structure of 4-methylpyridine-N-oxide (4-MePyO), has been studied by gas-phase electron diffraction monitored by mass spectrometry (GED/MS) and quantum chemical (DFT) calculations. Both, quantum chemistry and GED analyses resulted in $C_5$ molecular symmetry with the planar pyridine ring. Obtained molecular parameters confirm the hyperconjugation in the pyridine ring and the $sp^2$ hybridization concept of the nitrogen and carbon atoms in the ring. The experimental geometric parameters are in a good agreement with the parameters for non-substituted N-oxide and reproduced very closely by DFT calculations. The presence of the electron-donating CH$_3$ substituent in 4-MePyO leads to a decrease of the ipso-angle and to an increase of r(N–O) in comparison with the non-substituted PyO. Electron density distribution analysis has been performed in terms of natural bond orbitals (NBO) scheme. The nature of the semipolar N–O bond is discussed.

1. Introduction

The considerable interest to the heterocyclic compounds containing N-oxide group is caused by their pronounced biological activity [1]. Among the representatives of this class, there are compounds with bactericidal, analgesic, anticonvulsant activity, as well as ones with apoptotic, antifungal and antimicrobial activity [2,3]. These properties allow to use N-oxides as inhibitor of HIV-1 reverse transcriptase [4,5], as antiviral agent against various SARS coronavirus strains [6], and as antiadhesive and quorum-sensitive inhibitor [7]. In the literature one can find the evidence, that some complexes with pyridine-N-oxides are used in agriculture to regulate plant growth rates [8]. It was shown that pyridine-N-oxide derivatives are genotoxic [9]. The biochemical activity of N-oxides is usually considered to be the result of complexation with the metalloporphyrins in living organisms [10–12]. The reactivity of N-oxides may vary due to different substituents in the ring [13]. The variation of the substituents gives wide possibilities to chemical modifications of N-oxides and allows to influence their complexing properties, and, as the result, their biological activity.

To understand the complexation ability of N-oxides with different substituents the detailed information about the properties of free molecules is needed.

The available literature data about molecular structure of N-oxides can not be considered comprehensive. Thus, only pyridine-N-oxide and three of its para-substituted compounds have been studied by gas-electron diffraction (GED) [14,15]. Analyzing the average values of bond lengths in the pyridine ring the authors of [15] have concluded that the aromaticity increases in the series: 4-nitropyridine-N-oxide (4-NO$_2$PyO), 4-chloropyridine-N-oxide (4-ClPyO), pyridine-N-oxide (PyO), 4-methylpyridine-N-oxide (4-MePyO). The crystal structures of PyO, 4-NO$_2$PyO and 4-MePyO have been studied by X-ray crystallography [16,17]. The quantum chemical study of the substituent effect on the properties of pyridine-N-oxides has been performed for ten compounds with different substituents [18]. The comparative analysis of structural data obtained by different methods suggests that the molecular parameters of N-oxides obtained by GED [15] look rather strange. Thus, the N–C bond lengths in 4-NO$_2$PyO, 4-MePyO, 4-ClPyO recommended in Ref. [15] are even longer than r(C–C) in benzene ring, and seems to be overestimated compared to the calculated values and X-ray data. Moreover, the bond distance r(N–O) in 4-MePyO molecule recommended by authors [15] appears to be significantly underestimated and conflicting with the calculated and X-ray...
values. Furthermore, the accuracy of GED data obtained in Refs. [14,15] cannot be considered today as satisfactory.

The discrepancies in molecular structure of substituted N-oxides according to GED and other methods motivated us to perform a new gas-electron diffraction study of 4-methylpyridine-N-oxide. This molecule has been chosen because of the largest structural contradictions. Now more sophisticated methods for the analysis of GED data are available, including the possibility of quantum chemical results to be used in the interpretation of experimental data. This allows us to determine the structural parameters more precisely compared to the studies performed in 1982.

2. Experimental part

The electron diffraction patterns and the mass spectra were recorded simultaneously using the techniques described previously [19,20]. Two series of GED/MS experiments at two different nozzle-to-plate distances were performed. The conditions of GED/MS experiments and the relative abundance of the characteristic ions of 4-MePyO are shown in Tables 1 and 2, respectively. The temperature of stainless steel effusion cell was measured by a W/Re-5/20 thermocouple, which was standardised using the melting points of Sn and Al. Polycrystalline ZnO was used to establish the wavelength of the fast electrons. Microphotometric measurements were carried out by means of automatic techniques [32]. The molecular intensities were obtained in the ranges 2.5–28.7 Å⁻¹ (short camera) and 1.3–15.5 Å⁻¹ (long camera). The molecular intensities and the radial distributing curves are shown in Figs. 2 and 3 respectively.

3. Quantum chemical calculation

Quantum chemical calculations were carried out with GAUSSIAN 03 program set [21]. A hybrid DFT computational methods, namely B3LYP [22–26] and PBE0 [27], as well as MP2 method, were used. Structure optimizations were followed by calculations of the vibrational frequencies in order to ensure that a minimum on the potential energy hyper-surface had been reached.

Analysis of the potential functions of methyl group internal rotation shows that there is only one stable geometric con

![Fig. 1. Molecular structure of 4-methyl-pyridine-N-oxide and atom notations.](image)

![Fig. 2. Experimental (dots) and theoretical (solid) molecular intensity curves for 4-MePyO and the difference (experimental − theoretical) at two nozzle-to-plate distances, L₁ = 598 mm and L₂ = 338 mm.](image)

| m/e | Ion | Relative abundance, I, % |
|-----|-----|--------------------------|

| 66  | [C₄H₄N⁺]+ | 25                       |
| 52  | [C₄H₄⁺]⁺ | 54                       |

* M = C₆H₅NO.
4. Structure analysis

The heaviest ion in the mass spectrum observed during the GED/MS experiment was [Me-PyO]+ (Table 2). No ions were detected, which could arise from impurities. This proves the monomeric vapour composition under the conditions of the GED experiment.

The theoretical \( sM(s) \) functions were calculated with the following assumptions. Independent \( n_{i1} \) parameters were used to describe the molecular structure. Starting parameters from B3LYP/cc-pVTZ calculations were refined. The differences between all C–C, as well as between all C–H bond lengths were constrained to calculate values (B3LYP/cc-pVTZ). In compliance with the quantum chemical calculation results, a planar skeleton with \( C_2v \) symmetry of the pyridine ring was assumed. The methyl group was considered in the framework of \( C_{3v} \) symmetry. Vibrational amplitudes were refined in groups with fixed differences (Table 4). Only two correlation coefficients had absolute values larger than 0.7: (\( r(N-C3) \))/ (\( r(C2-C3) \)) = −0.74, and (\( \angle NC3C2 \))/ (\( \angle C3NC4 \)) = −0.84. The best agreement factor is \( R_f = 3.4% \). Final results of the least squares analysis are given in Table 3 (geometric parameters) and Table 4 (vibrational amplitudes).

5. Results and discussion

Table 3 summarizes the structural parameters of 4-Me-PyO. We can note a perfect agreement between calculated and experimental molecular structure parameters. The molecule possesses almost \( C_5 \) symmetry (the torsional angle H5C6C1C2 is close to 90°) with the planar pyridine ring. Table 5 compares gas-phase structures of PyO and 4-Me-PyO obtained in Refs. [14,15] and in this work. The parameters obtained in our research is in a good agreement with the theoretical results (therein and [18]) and, also, with the parameters for non-substituted N-oxide in contrast to the values recommended by Chiang J. F. et al. [15]. Furthermore, the parameters of free molecules of PyO [14] and 4-Me-PyO obtained in this work are in a good agreement with the crystal structures [34,35]. Apparently, some increase of the semipolar N–O bond lengths in the crystal phase compared to free molecules is due to intermolecular hydrogen bonding. All parameters presented in Table 5 confirm the hyperconjugation in the pyridine ring and the sp2 hybridization concept of the nitrogen and carbon atoms in the ring. The exceptions are only the data by Chiang J. F. et al. [15], which look rather strange.

Unfortunately, the correct comparison of GED parameters of 4-MePyO and non-substituted pyridine-N-oxide looks to be impossible because of large uncertainties in GED values obtained for PyO [14]. According to quantum chemical calculations the insertion of the methyl group in \( para \) position to the PyO has no significant effect on the structural parameters of the pyridine ring, excluding only the ipso-angle \( \angle C2C1C5 \), which changes from 120.6° in PyO to 115.9° in 4-MePyO (B3LYP/cc-pVTZ). It is interesting to note, that the substituent effects on the geometry of heterocyclic ring are rather similar to the tendencies for the benzene ring [36,37]. Thus, the presence of the electron-donating CH3 substituent leads to the decrease of the ipso-angle. Furthermore, according to the calculations the \( r(N\rightarrow O) \) bond lengths appear to be also sensitive to a

### Table 3

| Parameter | Experimental | B3LYP/cc-pVTZ | PBE0/cc-pVTZ | MP2/cc-pVTZ |

The C—C bond order for 4-MePyO corresponds to the single C—C bond. It is interesting to note that Q(N—O) in both molecules cannot be interpreted as exact single or double bond. Moreover, the introduction of an electron-donating substituent increases the bond length N—O, slightly reduces the corresponding bond order and significantly increases the electron density on the oxygen. One can conclude that in this case the nucleophilic properties of the molecule increase. Furthermore, as it has been mentioned previously [18] the introduction of electron-donating substituents to the heterocyclic ring of N-oxides results in increasing ability for complex formation. Our experimental and calculated data (Tables 3, 6 and 7) reveal the incorrectness of the authors of [15] in their conclusion about more single N—O bond character in 4-MePyO.

The delocalization of electron density between occupied Lewis values of the distances from Tables 3 and 5 show that these bonds do not correspond to either single nor double bonds. This confirms the existence of π-conjugation in the pyridine rings. The C1—C6 bond order for 4-MePyO corresponds to the single C—C bond. It is interesting to note that Q(N—O) in both molecules cannot be interpreted as exact single or double bond. Moreover, the introduction of an electron-donating substituent increases the bond length N—O, slightly reduces the corresponding bond order and significantly increases the electron density on the oxygen. type (bonds or lone pairs) NBO orbitals and formally unoccupied (antibonding) non-Lewis NBO orbitals corresponds to a stabilizing donor-acceptor interaction. The energy of these interactions can be estimated by the second order perturbation theory. Table 7 collects the largest values of calculated second order interaction energies ($E^2$) between donor-acceptor orbitals in PyO and 4-MePyO. In both cases several values correspond to the interactions related to the resonance in the pyridine ring, i.e. the interactions between $\pi$(C–C) and $\pi^*(C–C)$ and between $\pi^*(C–N)$ and $\pi^*(N–C)$. The nature of semipolar N–O bond was explained in detail [18]. The largest second order interaction energies ($E^2$) in both molecules correspond to the LP3(O) interaction with the antibonding $\pi^*(N–C)$ NBO (Fig. 4.). Such interaction can lead to partial transfer of electron density from LP3(O) to the $\pi$-system of the pyridine ring. As the result, the occupancy of the LP3(O) $\sigma^*$-orbital of oxygen is only 1.62e or 1.65e in PyO and 4-MePyO, respectively.

To study the substituent effect on the aromaticity the nuclear independent chemical shifts NICS(1) have been calculated by using B3LYP/aug-cc-pVTZ approximation. NICS(1) values correspond to the largest values of calculated second order interaction energies ($E^2$) in both molecules correspond to the LP3(O) interaction with the antibonding $\pi^*(N–C)$ NBO (Fig. 4.). Such interaction can lead to partial transfer of electron density from LP3(O) to the $\pi$-system of the pyridine ring. As the result, the occupancy of the LP3(O) $\sigma^*$-orbital of oxygen is only 1.62e or 1.65e in PyO and 4-MePyO, respectively.
