Abstract. The Askey–Wilson algebra and its relatives such as the Racah
and Bannai–Ito algebras were initially introduced in connection with
the eponym orthogonal polynomials. They have since proved ubiquitous.
In particular they admit presentations as commutants that are related
through Howe duality. This paper surveys these results.

Keywords: Howe duality, Racah, Bannai–Ito and Askey–Wilson alge-
bras, commutants, reductive dual pairs.

1 Introduction

The quadratic algebras of Askey–Wilson type such as the Askey–Wilson algebra itself, the Racah and Bannai–Ito algebras and their specializations and contrac-
tions encode the bispectral properties of orthogonal polynomials that arise in
recoupling coefficients such as the Clebsch–Gordan or Racah coefficients. It is
therefore natural that these algebras be encountered as centralizers of the diag-
onal action of an algebra of interest $g'$ such as $\mathfrak{sl}(2)$, $\mathfrak{osp}(1|2)$ or $U_q(\mathfrak{sl}(2))$, on
$n$-fold tensor products of representations of $g'$. Indeed, elements of these central-
izers will be used as labelling operators to define bases whose overlaps will be
expressed in terms of the corresponding orthogonal polynomials.

Often the algebra $g'$ forms a reductive pair with another algebra $g$ in which
case the Howe duality operates in certain modules. This leads to alternative char-
acterizations of the quadratic algebras that are in correspondence: on the one
hand commutants in representations of the universal enveloping algebra $U(g)$
and on the other hand, realizations of the type mentioned above as centralizers
in recoupling problems for $g'$. This is the topic of this brief review which is organ-
ized as follows. Section 2 presents the general framework. Section 3 describes as
illustration the dual commutant picture for the Racah algebra; this will involve
the reductive pair $(\mathfrak{o}(6), \mathfrak{su}(1,1))$. Section 4 gives a summary of the different
cases that have been analyzed and Section 5 provides a short outlook.
2 General Framework

We shall say following [1] that two algebras \( g \) and \( g' \) have dual representations on a Hilbert space \( \mathcal{H} \) if (1) this space carries fully reducible representations of both \( g \) and \( g' \), (2) the action of \( g \) and \( g' \) commute, (3) the representation \( \rho \) of the direct sum \( g \oplus g' \) defined by the actions of \( g \) and \( g' \) on \( \mathcal{H} \) is multiplicity-free and (4) each irreducible representation of \( g \) occurring in the decomposition of \( \rho \) is paired with a unique irreducible representation of \( g' \) and vice-versa. This is the essence of Howe duality which can be proved in a number of situations. We shall consider such instances in this paper.

Consider now a setup with the representation of \( g' \) in \( \mathcal{H} = V^\otimes 2n \) given by \( \tilde{\sigma}^\otimes 2n[\Delta^{(2n-1)}(g')] \) where \( \tilde{\sigma} : g' \rightarrow \text{End} V \) is a representation of \( g' \) on the vector space \( V \). \( \Delta : g' \rightarrow g' \otimes g' \) is the coproduct and \( \Delta^{(n)} \) is defined recursively by \( \Delta^{(n)} = (\Delta \otimes 1 \otimes (n-1)) \circ \Delta^{(n-1)} \), with \( \Delta^{(0)} = 1 \). This symmetric situation makes it natural that there be an action of some other algebra \( \mathfrak{g} \) on the carrier space \( \mathcal{H} \) that commutes with the action of \( g' \). Take the maximal Abelian subalgebra \( \mathfrak{h} \) of \( \mathfrak{g} \) to be \( \mathfrak{h} \simeq \mathfrak{x}^\otimes n \) with \( \mathfrak{x} \) one-dimensional. The pairing under Howe duality with the representations of \( \mathfrak{x}^\otimes n \) implies that \( \tilde{\sigma}^\otimes 2n[\Delta^{(2n-1)}(g')] = \tilde{\sigma}^\otimes 2n[\Delta^{\otimes n} \circ \Delta^{(n-1)}(g')] \) decomposes into representations of the form \( \sigma_1 \otimes \sigma_2 \otimes \cdots \otimes \sigma_n(\Delta^{(n-1)}(g')) \) with the \( \sigma_i \)'s being irreducible representations arising in the decomposition of \( \tilde{\sigma}^\otimes 2 \).

This quotienting by \( \mathfrak{h} \) is a way of posing a generalized Racah problem for the recoupling of the \( n \) representations \( \sigma_i \) of \( g' \).

We indicated in the introduction that the quadratic algebras \( \mathcal{A} \) of Askey–Wilson type can be obtained as (subalgebras of) centralizers of diagonal actions in \( n \)-fold tensor products of representations. The intermediate Casimir elements in \( \sigma_1 \otimes \sigma_2 \otimes \cdots \otimes \sigma_n \) manifestly centralize the action of \( g' \) on \( \mathcal{H} \) mod \( \mathfrak{h} \). They are taken to generate the quadratic algebra of interest. This provides the first presentation of \( \mathcal{A} \) as a commutant. The dual one is identified as follows in the present context. We know that \( \mathfrak{g} \) is the commutant of \( g' \) in \( \mathcal{H} \). Moreover from the application of Howe duality, the generators of the representation \( \sigma_1 \otimes \sigma_2 \otimes \cdots \otimes \sigma_n \) of \( g' \) are known to commute with those that represent the subalgebra \( \mathfrak{h} \simeq \mathfrak{x}^\otimes n \).

The non-trivial part of the centralizer of \( \sigma_1 \otimes \sigma_2 \otimes \cdots \otimes \sigma_n \) must therefore be obtained, in the given representation on \( \mathcal{H} \) mod \( \mathfrak{h} \), by those elements in the universal enveloping algebra of \( \mathfrak{g} \) that commute with \( \mathfrak{x}^\otimes n \). In other words, \( \mathcal{A} \) can also be identified as the commutant of \( \mathfrak{h} \subset \mathfrak{g} \) in \( \mathcal{U}(\mathfrak{g}) \) as represented on \( \mathcal{H} \).

There is an equivalent way of looking at this. The pairing of the representations of \( g \) and \( g' \) through Howe duality manifests itself in the fact that the Casimir elements of \( g \) and \( g' \) are affinely related. Let \( \mathcal{C} \) be a Casimir element of \( g' \). Consider for example the intermediate Casimir element given by \( \tilde{\sigma}^\otimes 4[(\Delta \otimes \Delta) \circ \Delta](\mathcal{C}) \otimes 1^{\otimes (2n-4)} \) corresponding to the embedding of \( g' \) in the first four factors of \( g'^\otimes 2n \). There will be a subalgebra \( g_1 \) of \( g \) that will be dually related to \( g' \) on the restriction of \( \mathcal{H} \) to \( V^\otimes 4 \) so that its Casimir element will be essentially the one of \( g' \). Next, looking at the intermediate Casimir element of \( g' \) associated to a different embedding, for instance in the four last factors of \( g'^\otimes 2n \), there will be a dual pairing with a different embedding in \( g \) of the same subalgebra \( g_1 \) and again the two Casimir elements will basically coincide.
These observations lead to the conclusion that the set of intermediate Casimir elements associated to the representation of $g'$ is algebraically identical to the set of Casimir elements of the subalgebras of $g$ that form dual pairs with $g'$ when intermediate representations of the latter are taken. It is not difficult to convince oneself that the set of invariants connected to the relevant subalgebras of $g$ consists in the commutant of the maximal Abelian subalgebra of $g$ as concluded differently before.

To summarize, in situations where Howe duality prevails with $(g, g')$ the pair of algebras that are dually represented on $H$ consists in the commutant of the maximal Abelian subalgebra of $g$; mutation relations: 

$$\text{oneself that the set of invariants connected to the relevant subalgebras of } g \text{ that form dual pairs with } g' \text{ when intermediate representations of the latter are taken.}$$

It is not difficult to convince oneself that the set of invariants connected to the relevant subalgebras of $g$ consists in the commutant of the maximal Abelian subalgebra of $g$ as concluded differently before.

3 The dual presentations of the Racah algebra

The Racah algebra $R$ has three generators $K_1, K_2, K_3$ that are subjected to the relations [2]:

$$[K_1, K_2] = K_3, \quad [K_2, K_3] = K_2^2 + \{K_1, K_2\} + dK_2 + e_1, \quad [K_3, K_1] = K_1^2 + \{K_1, K_2\} + dK_1 + e_2,$$

where $[A, B] = AB - BA$, $\{A, B\} = AB + BA$ and $d, e_1, e_2$ are central.

We shall explain how dual presentations of the algebra $R$ as a commutant are obtained in the fashion described in Section 2. The dual pair will be $(\mathfrak{o}(6), \mathfrak{su}(1,1))$ and the representation space $H$ will be that of the state space of six quantum harmonic oscillators with annihilation and creation operators $a_{\mu}, a^\dagger_{\mu}$, $\mu, \nu = 1, \ldots, 6$ verifying $[a_{\mu}, a^\dagger_{\nu}] = \delta_{\mu\nu}$. The corresponding Hamiltonian $H = a^\dagger_1 a_1 + \cdots + a^\dagger_6 a_6$ is manifestly invariant under the rotations in six dimensions. These are encoded in the Lie algebra $\mathfrak{o}(6)$, realized by the generators $L_{\mu\nu} = a^\dagger_\mu a_\nu - a_\mu a^\dagger_\nu$ and possessing the Casimir element $C = \sum_{\mu<\nu} L_{\mu\nu}^2$.

The Lie algebra $\mathfrak{su}(1,1)$ has generators $J_0, J_\pm$ that obey the following commutation relations: $[J_0, J_\pm] = \pm J_\pm$, $[J_+, J_-] = -2J_0$, and its Casimir operator is given by $C = J_0^2 - J_+ J_- - J_0$. The six harmonic oscillators also provide a realization of this algebra through the addition of six copies of the metaplectic representation of $\mathfrak{su}(1,1)$, for which the generators are mapped to: $J_0^{(\mu)} = \frac{1}{2}(a^\dagger_\mu a_\mu + \frac{1}{2})$, $J_+^{(\mu)} = \frac{1}{2}(a^\dagger_\mu)^2$, $J_-^{(\mu)} = \frac{1}{2}(a_\mu)^2$, $\mu = 1, \ldots, 6$. Note that the operators $\sum_{\mu=1}^6 J_\mu^{(\mu)}$ are invariant under rotations. The space of state vectors $H$ thus carries commuting representations of $\mathfrak{o}(6)$ and $\mathfrak{su}(1,1)$ and Howe duality takes place.

The maximal Abelian algebra of $\mathfrak{o}(6)$ is $\mathfrak{o}(2) \oplus \mathfrak{o}(2) \oplus \mathfrak{o}(2)$ and is generated by the set $\{L_{12}, L_{34}, L_{56}\}$. The non-abelian part of its commutant in the repre-

---

Note: The above text is a transcription of the content from the image provided, ensuring proper formatting and coherence. The content discusses the relationship between algebras and their representations, focusing on the dual pairs and how they are realized in the context of the Racah algebra.
representation of $\mathcal{U}(\mathfrak{so}(6))$ on $\mathcal{H}$ is generated by the two invariants
\begin{align}
K_1 &= \frac{1}{8}(L_{12}^2 + L_{34}^2 + L_{13}^2 + L_{23}^2 + L_{14}^2 + L_{24}^2), \\
K_2 &= \frac{1}{8}(L_{34}^2 + L_{56}^2 + L_{35}^2 + L_{36}^2 + L_{45}^2 + L_{46}^2).
\end{align}
Define $K_3$ by $[K_1, K_2] = K_3$. Working out the commutation relations of $K_3$ with $K_1$ and $K_2$, it is found that they correspond to those of the Racah algebra with the central parameters given by $d = -\frac{1}{8}(C + L_{12}^2 + L_{34}^2 + L_{56}^2)$, $e_1 = -\frac{1}{16}(C - L_{12}^2 - 4)\left(L_{34}^2 - L_{56}^2\right)$ and $e_2 = -\frac{1}{16}(C - L_{56}^2 - 4)\left(L_{34}^2 - L_{12}^2\right)$.

For details see [3]. By abuse of notation we designate the abstract generators and their realizations by the same letter.

Regarding the $\mathfrak{su}(1,1)$ picture, let $J^{(\mu, \nu, \rho, \lambda)} = J^{(\mu)} + J^{(\nu)} + J^{(\rho)} + J^{(\lambda)}$ denote the addition of the four metaplectic representations labelled by the variables $\mu, \nu, \rho, \lambda$ all assumed different. The corresponding Casimir operator is $C^{(\mu, \nu, \rho, \lambda)} = \left(J_0^{(\mu)} + J_0^{(\nu)} + J_0^{(\rho)} + J_0^{(\lambda)}\right)^2 - J_+^{(\mu, \nu, \rho, \lambda)}J_-^{(\mu, \nu, \rho, \lambda)} - J_0^{(\mu, \nu, \rho, \lambda)}$. Quite clearly, these actions of $\mathfrak{su}(1,1)$ restricted to state vectors of four oscillators are paired with commuting actions of the Lie algebra $\mathfrak{so}(4)$ of rotations in the four dimensions labelled by $\mu, \nu, \rho, \lambda$. It is hence not surprising to find, owing to Howe duality, that $C^{(1234)} = -2K_1$ and $C^{(3456)} = -2K_2$, namely that the intermediate $\mathfrak{su}(1,1)$ Casimir operators corresponding to the recouplings of the first four and last four of the six metaplectic representations are equal (up to a factor) to the Casimir elements of the two corresponding $\mathfrak{so}(4)$ subalgebras of $\mathfrak{so}(6)$ which together generate as we observed the non-trivial part of the commutant of $\mathfrak{so}(2) \oplus \mathfrak{so}(2) \oplus \mathfrak{so}(2)$ in $\mathcal{U}(\mathfrak{so}(6))$. This entails the description of the Racah algebra as the commutant in $\mathcal{U}(\mathfrak{su}(1,1)^{\otimes 3})$ of the action of $\mathfrak{su}(1,1)$ on $\mathcal{H}$. Alternatively, picking the $\mathfrak{su}(1,1)$ representations associated to those of $\mathfrak{so}(2) \oplus \mathfrak{so}(2) \oplus \mathfrak{so}(2)$ under Howe duality yields the sum of three irreducible representations of $\mathfrak{su}(1,1)$ belonging to the discrete series; these are realized as dynamical algebras of three singular oscillators. Note that corresponding to the $\mathfrak{su}(1,1)$ representation $J^{(\mu, \nu)} = J^{(\mu)} + J^{(\nu)}$ is the Casimir $C^{(\mu, \nu)} = -\frac{1}{8}(L_{\mu \nu}^2 + 1)$. With the dependance on the polar angles “rotated out”, the total Casimir element $C^{(123456)}$ becomes the Hamiltonian of the generic superintegrable system on the two-sphere; the constants of motion are the quotiented intermediate Casimirs elements and the symmetry algebra that they generate is hence that of Racah.

4 More dual pictures – an overview

The main algebras of Askey–Wilson type have been studied recently from the commutant and Howe duality viewpoints. We summarize in the following the main results and give in particular the dualities that are involved.

4.1 The Racah family

The higher rank extension of the Racah algebra defined as the algebra generated by all the intermediate Casimir elements of $\sigma_1 \otimes \sigma_2 \otimes \cdots \otimes \sigma_n(\Delta^{(n-1)}(\mathfrak{su}(1,1)))$
can be described in the framework of the preceding section with the help of the dual pair \((\mathfrak{o}(2n), \mathfrak{su}(1,1))\) using in this case the module formed by the state vectors of \(2n\) harmonic oscillators. It is then seen to be dually the commutant of \(\mathfrak{o}(2)\) in the oscillator representation of \(\mathcal{U}(\mathfrak{o}(2n))\) [4].

The case \(n = 2\) is special and of particular interest since it pertains to the Clebsch–Gordan problem for \(\mathfrak{su}(1,1)\), that is, the recoupling of the two irreducible representations \(\sigma_1\) and \(\sigma_2\). There are no intermediate Casimirs here; the relevant operators associated to the direct product basis and the recoupled one are respectively \(M_1 = \sigma_1(J_0) - \sigma_2(J_0)\) and the total Casimir \(M_2 = (\sigma_1 \otimes \sigma_2)\Delta(C)\). These are seen to obey the commutation relations of the Hahn algebra [5]:

\[
\begin{align*}
[M_1, M_2] &= M_3, \\
[M_2, M_3] &= -2\{M_1, M_2\} + \delta_1, \\
[M_3, M_1] &= -2M_1^2 - 4M_2 + \delta_2,
\end{align*}
\]

where \(\delta_1 = 4(\sigma_1(J_0) + \sigma_2(J_0))(\sigma_1(C) - \sigma_2(C))\) and \(\delta_2 = 2(\sigma_1(J_0) + \sigma_2(J_0))^2 + (\sigma_1(C) + \sigma_2(C))\) are central. The name of the algebra comes from the fact that the \(3j\)-coefficients involve dual Hahn polynomials. In the setup with four harmonic oscillators, with \(\mathcal{H}\) carrying the product of four metaplectic representations, Howe duality implies that the total Casimir element \(C^{(1234)}\) of \(\mathfrak{su}(1,1)\) coincides with the Casimir of \(\mathfrak{o}(4)\) – this is the same computation as the one described above. It is easily seen that \(\sigma_1(J_0) - \sigma_2(J_0)\) is derived from \(\frac{1}{2}(N_1 + N_2 - N_3 - N_4)\) under the quotient by \(\mathfrak{o}(2) \oplus \mathfrak{o}(2)\) with \(N_i = a_i^\dagger a_i, \ i = 1, \ldots, 4\). It can in fact be checked directly, again abusing notation, that \(M_1 = \frac{1}{2}(N_1 + N_2 - N_3 - N_4)\) and \(M_2 = -\frac{1}{2}(L_{12}^2 + L_{34}^2 + L_{13}^2 + L_{23}^2 + L_{14}^2 + L_{24}^2)\) satisfy the relations given in equation [4] with \(\delta_1 = -\frac{1}{2}(N_1 + N_2 + N_3 + N_4 + 2)(L_{12}^2 - L_{34}^2)\) and \(\delta_2 = \frac{1}{2}(N_1 + N_2 + N_3 + N_4 + 2)^2 - (L_{12}^2 + L_{34}^2 + 2)\), in correspondence with the preceding expressions for \(\delta_1\) and \(\delta_2\) in the realization \(J^{(1234)}\) of \(\mathfrak{su}(1,1)\). From the expressions of these last \(M_1\) and \(M_2\), we can claim that the Hahn algebra is the commutant of \(\mathfrak{o}(2) \oplus \mathfrak{o}(2)\) in \(\mathcal{U}(\mathfrak{u}(4))\) represented on \(\mathcal{H}\). Let us stress that it is the universal enveloping algebra of \(\mathfrak{u}(4)\) that intervenes here.

### 4.2 The Bannai–Ito set

The Bannai–Ito algebra [6] takes its name after the Bannai–Ito polynomials that enter in the Racah coefficients of the Lie superalgebra \(\mathfrak{osp}(1|2)\). This algebra has three generators \(K_i, \ i = 1, \ldots, 3\) that satisfy the relations

\[
\{K_i, K_j\} = K_k + \omega_k, \quad i \neq j \neq k \in \{1, 2, 3\}
\]

with \(\omega_i\) central and \(\{X, Y\} = XY + YX\). The relevant reductive pair in this case is \((\mathfrak{o}(6), \mathfrak{osp}(1|2))\) and the representation space \(\mathcal{H}\) is that of Dirac spinors in six dimensions with the Clifford algebra generated by the elements \(\gamma_\mu\) verifying \(\{\gamma_\mu, \gamma_\nu\} = -2\delta_\mu\nu\). \(\mu, \nu = 1, \ldots, 6\). That the pair \((\mathfrak{o}(6), \mathfrak{osp}(1|2))\) is dually represented on \(\mathcal{H}\) is seen as follows: The spinorial representation of \(\mathfrak{o}(6)\) with generators

\[
J_{\mu\nu} = -i(x_\mu \partial_\nu - x_\nu \partial_\mu) + \Sigma_{\mu\nu}, \quad \Sigma_{\mu\nu} = \frac{i}{2} \gamma_\mu \gamma_\nu
\]
leaves invariant the following operators:

\[
J_- = -i \sum_{\mu=1}^{6} \gamma_{\mu} \partial_{\mu}, \quad J_+ = -i \sum_{\mu=1}^{6} \gamma_{\mu} x_{\mu}, \quad J_0 = \sum_{\mu=1}^{6} x_{\mu} \partial_{\mu}, \tag{7}
\]

which in turn realize the commutation relations of the Lie superalgebra \( \mathfrak{osp}(1|2) \):

\[
[J_0, J_\pm] = \pm J_\pm, \quad [J_+, J_-] = -2J_0 \quad \text{with } J_0 \text{ even and } J_\pm \text{ odd.}
\]

Hence, duality thus takes place. As a matter of fact, for any subset \( \Gamma \subset \{1, \ldots, 6\} \) of cardinality \( |\Gamma| \), the operators \( J^A = -i \sum_{\mu \in \Gamma} \gamma_{\mu} \partial_{\mu} \), \( J_+^A = -i \sum_{\mu \in \Gamma} \gamma_{\mu} x_{\mu} \), and \( J_0^A = \frac{|\Gamma|}{2} + \sum_{\mu \in \Gamma} x_{\mu} \partial_{\mu} \) realize \( \mathfrak{osp}(1|2) \). The Casimir element of \( \mathfrak{osp}(1|2) \) is given by

\[
C = \frac{1}{2}([J_+, J_-] - 1)S \quad \text{with } S \text{ the grade involution obeying } S^2 = 1, \quad [S, J_0] = 0, \quad \{S, J_\pm\} = 0.
\]

In the realizations at hand, \( S^A = i^{A/2} \prod_{\mu \in \Gamma} \gamma_{\mu} \) with \( |\Gamma| \) even.

It can be checked that the operators

\[
K_1 = M_1 + \frac{3}{2} \Sigma_{12} \Sigma_{34}, \quad K_2 = M_2 \times \frac{3}{2} \Sigma_{34} \Sigma_{56}, \quad K_3 = M_3 + \frac{3}{2} \Sigma_{12} \Sigma_{56},
\]

\[
M_1 = (L_{12} \gamma_{12} + L_{13} \gamma_{13} + L_{14} \gamma_{14} + L_{15} \gamma_{15} + L_{16} \gamma_{16} + L_{23} \gamma_{23} + L_{24} \gamma_{24} + L_{25} \gamma_{25} + L_{26} \gamma_{26} + L_{34} \gamma_{34} + L_{35} \gamma_{35} + L_{36} \gamma_{36} + L_{45} \gamma_{45} + L_{46} \gamma_{46} + L_{56} \gamma_{56}) \Sigma_{12} \Sigma_{34},
\]

\[
M_2 = (L_{34} \gamma_{34} + L_{35} \gamma_{35} + L_{36} \gamma_{36} + L_{45} \gamma_{45} + L_{46} \gamma_{46} + L_{56} \gamma_{56}) \Sigma_{34} \Sigma_{56},
\]

\[
M_3 = (L_{12} \gamma_{12} + L_{13} \gamma_{13} + L_{14} \gamma_{14} + L_{15} \gamma_{15} + L_{16} \gamma_{16} + L_{23} \gamma_{23} + L_{24} \gamma_{24} + L_{25} \gamma_{25} + L_{26} \gamma_{26} + L_{34} \gamma_{34} + L_{35} \gamma_{35} + L_{36} \gamma_{36} + L_{45} \gamma_{45} + L_{46} \gamma_{46} + L_{56} \gamma_{56}) \Sigma_{12} \Sigma_{56}
\]

realize the relations (6) of the Bannai–Ito algebra upon taking the following:

\[
\omega_{ij} = 2 \Gamma_i \Gamma_{123} + 2 \Gamma_j \Gamma_i, \quad \Gamma_1 = J_{12}, \quad \Gamma_2 = J_{34}, \quad \Gamma_3 = J_{56}, \quad \text{and } \Gamma_{123} = \left( \frac{3}{2} - i \sum_{1 \leq \mu < \nu \leq 6} L_{\mu \nu} \Sigma_{\mu \nu} \right) \Sigma_{12} \Sigma_{34} \Sigma_{56}.
\]

That these arise from dual pictures is explained as follows (see [7] for details). On the one hand, \( K_1, K_2, K_3 \) are observed to belong to the commutant in \( \mathcal{U}(\mathfrak{o}(6)) \) of the \( \mathfrak{o}(2) \oplus \mathfrak{o}(2) \oplus \mathfrak{o}(2) \) subalgebra of \( \mathfrak{o}(6) \) spanned by \( \{J_{12}, J_{34}, J_{56}\} \). On the other hand, considering the Casimir elements \( C^A \) of \( \mathfrak{osp}(1|2) \) associated to the realization by the operators \( \{J^A, J_\pm^A, S^A\} \), we find that \( C^{(1234)} = K_1, \quad C^{(3456)} = K_2 \) and \( C^{(1256)} = K_3 \).

This confirms that the Bannai–Ito algebra can be dually presented either as the commutant of \( \mathfrak{o}(2) \oplus \mathfrak{o}(2) \oplus \mathfrak{o}(2) \) in the spinorial representation of \( \mathcal{U}(\mathfrak{o}(6)) \) or as the centralizer of the action of \( \mathfrak{osp}(1|2) \) on \( \mathcal{H} \). These considerations can be extended to higher dimensions [7] so as to obtain analogously dual commutant pictures for the Bannai–Ito algebras of higher ranks.

### 4.3 The Askey–Wilson class

The Askey–Wilson algebra can be presented as follows:

\[
\begin{align*}
\frac{[K_A, K_B]}{q^2 - q^{-2}} + K_C &= \frac{\gamma}{q + q^{-1}}, & \frac{[K_B, K_C]}{q^2 - q^{-2}} + K_A &= \frac{\alpha}{q + q^{-1}}, \\
\frac{[K_C, K_A]}{q^2 - q^{-2}} + K_B &= \frac{\beta}{q + q^{-1}},
\end{align*}
\]

with \( [A, B]_q = qAB - q^{-1}BA \) and \( \alpha, \beta, \gamma \) central.
The \( U_q(\mathfrak{su}(1, 1)) \) algebra has three generators, \( J_\pm \) and \( J_0 \), obeying \([J_0, J_\pm] = \pm J_\pm\) and \( J_- J_+ - q^2 J_+ J_- = q^2 J_0 [2 J_0]_q \) with \([x]_q = \frac{q^x - q^{-x}}{q - q^{-1}}\). Its coproduct is defined by \( \Delta(J_0) = J_0 \otimes 1 + 1 \otimes J_0 \), \( \Delta(J_\pm) = J_\pm \otimes q^{2 J_0} + 1 \otimes J_\pm \). The Casimir operator \( C \) of \( U_q(\mathfrak{su}(1, 1)) \) is given by \( C = J_+ J_- J_0 - 2 q^2 J_0 + 1 = \frac{q^2 J_0 - 1 + q^{-2 J_0} + 1}{(1-q)^2} \).

The \( q \)-deformation \( \mathfrak{o}_{q^{1/2}}(N) \) of \( \mathfrak{o}(N) \) is defined as the algebra with generators \( L_{i,i+1} \) \((i = 1, \ldots, N - 1)\) obeying the relations
\[
\begin{align*}
L_{i-1,i} L_{i,i+1}^2 - (q^{1/2} + q^{-1/2}) L_{i,i+1} L_{i-1,i} + L_{i,i+1}^2 L_{i-1,i} &= -L_{i-1,i}, \\
L_{i,i+1} L_{i-1,i}^2 - (q^{1/2} + q^{-1/2}) L_{i-1,i} L_{i,i+1} + L_{i-1,i}^2 L_{i,i+1} &= -L_{i,i+1}, \\
[L_{i,i+1}, L_{j,j+1}] &= 0 \quad \text{for} \quad |i - j| > 1.
\end{align*}
\]

We shall use the notation \( L_{ik}^\pm = [L_{ij}, L_{jk}]_{q^{1/4}} \) for any \( i < j < k \), and by definition \( L_{ii}^\pm = L_{i,i+1} \).

The reductive pair \( (\mathfrak{o}_{q^{1/2}}(6), U_q(\mathfrak{su}(1, 1))) \) is the one which is of relevance for the Askey–Wilson algebra. Let us indicate how \( \mathfrak{o}_{q^{1/2}}(2n) \) and \( U_q(\mathfrak{su}(1, 1)) \) are dually represented on the standard state space \( H \) of \( 2n \) independent \( q \)-oscillators described by operators \( \{A_i^\pm, A_i^0\} \) such that \([A_i^0, A_j^\pm] = \pm A_i^\pm, \quad [A_i^-, A_i^+] = q^i \mathbf{1}, \quad A_i^+ A_j^- - A_j^- A_i^+ = 1, \quad i = 1, \ldots, 2n \). The algebra \( U_q(\mathfrak{su}(1, 1)) \) is represented on \( H \) by using the coproduct to embed it in the tensor product of \( 2n \) copies of the \( q \)-deformation of the metaplectic representation, this gives
\[
\begin{align*}
J_0^{(2n)} &= \Delta^{(2n-1)} \left( \frac{1}{2} (A_1^0 + \frac{1}{2}) \right) = \frac{1}{2} \sum_{i=1}^{2n} \left( A_i^0 + \frac{1}{2} \right), \\
J_\pm^{(2n)} &= \Delta^{(2n-1)} \left( \frac{1}{[2]_{q^{1/2}}} (A_i^\pm)^2 \right) = \frac{1}{[2]_{q^{1/2}}} \sum_{i=1}^{2n} \left( A_i^\pm \right)^2 \prod_{j=i+1}^{2n} q^{A_j^0 + \frac{1}{2}}.
\end{align*}
\]

The algebra \( \mathfrak{o}_{q^{1/2}}(2n) \) can also be realized in terms of \( 2n \) \( q \)-oscillators. The \( 2n - 1 \) generators take the form
\[
L_{i,i+1} = q^{-\frac{1}{2} (A_i^0 + \frac{1}{2})} \left( q^{\frac{1}{2} A_i^+ A_{i+1}^-} - q^{-\frac{1}{2} A_i^- A_{i+1}^+} \right), \quad i = 1, \ldots, 2n - 1.
\]

It can be checked that \([J_0^{(2n)}, L_{i,i+1}] = [J_\pm^{(2n)}, L_{i,i+1}] = 0, \quad i = 1, \ldots, 2n - 1\), in other words, that \( U_q(\mathfrak{su}(1, 1)) \) and \( \mathfrak{o}_{q^{1/2}}(2n) \) have commuting actions on the Hilbert space \( H \) of \( 2n \) \( q \)-oscillators. This sets the stage for Howe duality. In order to connect with the Askey–Wilson algebra we take \( n = 3 \). The expressions of the operators \( K_A \) and \( K_B \) acting on \( H \) that realize the relations \( \mathfrak{B} \) (together with the specific central elements) are rather involved and we shall refer the reader to \( \mathfrak{B} \) for the formulas. We shall only stress that these operators can be obtained in a dual way: They are affinely related to the generators of the commutant of \( \mathfrak{o}_{q^{1/2}}(2) \) in \( \mathfrak{o}_{q^{1/2}}(6) \) as well as to the intermediate \( U_q(\mathfrak{su}(1, 1)) \) Casimir elements \( C^{(1234)} = \Delta^{(3)}(C) \otimes 1 \otimes 1 \) and \( C^{(3456)} = 1 \otimes 1 \otimes \Delta^{(3)}(C) \) of the \( q \)-metaplectic representation (see \( \mathfrak{B} \)). This can be extended to higher ranks by letting \( n \) be arbitrary. For \( n = 2 \) we are looking at the Clebsch–Gordan problem.
for $U_q(\mathfrak{su}(1,1))$. The $q$-Hahn algebra that arises has two dual realizations [9]: one as the commutant of $\sigma_{q^{-1/2}}(2)\otimes 2$ in $U_q(\mathfrak{u}(4))$ and the other in terms of the following two $U_q(\mathfrak{su}(1,1))$ operators, $(\Delta(J_0)\otimes 1\otimes 1) - (1\otimes 1\otimes \Delta(J_0))$ and $\Delta^{(2)}(C)$ (the full Casimir element) in the $q$-metaplectic representation.

5 Conclusion

This paper has offered a summary of how the quadratic algebras of Racah, Hahn, Bannai–Ito, Askey–Wilson and $q$-Hahn types can be given dual descriptions as commutant of Lie algebras, superalgebras and quantum algebras. The connection between these dual pictures is rooted in Howe dualities whose various expressions have been stressed. The attentive reader will have noticed that the Clebsch–Gordan problem for $\mathfrak{osp}(1|2)$ has not been mentioned; this is because it has not been analyzed yet. We plan on adding this missing piece to complete the picture.
