Abstract

Based on the observation that the moduli of a link variable on a cyclic group modify Connes’ distance on this group, we construct several action functionals for this link variable within the framework of noncommutative geometry. After solving the equations of motion, we find that one type of action gives nontrivial vacuum solution for gravity on this cyclic group in a broad range of coupling constants and that such solutions can be expressed with Chebyshev’s polynomials.

Keywords: non-unitary link variable, Connes’ distance formula, vacuum solution, noncommutative geometry, cyclic group.

I Introduction

It is a marvelous property of noncommutative geometry (NCG) that Dirac operator induces a metric onto a space [1]. Specifying this result to a cyclic group, we discussed recently at the end of [2] that the effect of a non-unitary 1D link variable on this Connes’ distance is to modify a linear(Euclidean)-distance with the
moduli of this link variable. This feature indicates the general characteristics of NCG that gauge connection and metric are easily interwound on a noncommutative space. In this contribution, we will explore the (classical) gravitational physics of cyclic groups in depth. We construct action functionals for gravitational fields from Dirac operator, deduce the equations of motion, then solve them and give a series of vacuum solutions. It will be shown that in a broad range of coupling constants of one action functional, there is a non-trivial vacuum solution that can be expressed by Chebyshev’s polynomials and that breaks translation invariance. Of course, this model is just an exercise as a class of toy-models like [3][4]; however, it provides a lot of general features of NCG approach to gravity problems. For a more abstract and general treatment of noncommutative gravity, one can refer to Majid’s [5][6].

This paper is organized as the following way. In section II, NCG on a cyclic group is formulated, especially Dirac operator is defined. Several action functionals are established in section III. Three types of vacua will be found out, in which only the last one is nontrivial. Some opening discussions are put into section IV.

II NCG of Cyclic Groups: Kinematics of Dirac Operator

Let \( \mathbb{Z}_N \) be a \( N \)-order cyclic group \( \mathbb{Z}_N = \{0, 1, 2, \ldots, N - 1\} \) whose multiplication is just integer addition modulo \( N \). Additions appearing below are understood as additions in \( \mathbb{Z}_N \). \( \mathcal{A}(\mathbb{Z}_N) \) is the algebra of complex functions on \( \mathbb{Z}_N \) and there is a regular representation of \( \mathbb{Z}_N \) on \( \mathcal{A}(\mathbb{Z}_N) \) generated by \( (T^+ f)(x) = f(x + 1), \forall f \in \mathcal{A}(\mathbb{Z}_N), x \in \mathbb{Z}_N \). For any finite \( N \), \((T^+)^N = 1\) where \( 1 \) is identity transformation on \( \mathcal{A}(\mathbb{Z}_N) \); hence \( T^- := (T^+)^{-1} = (T^+)^{-1} \). A spinor space \( \mathcal{H}_s = \mathbb{C}^2 \) is introduced to each point of \( \mathbb{Z}_N \); a fermion field on \( \mathbb{Z}_N \) is an element in \( \mathcal{H} := \mathcal{A}(\mathbb{Z}_N) \otimes \mathcal{H}_s \). Under the standard inner product on \( \mathcal{H} \), \( T^+ \) is a unitary operator. A Fredholm operator acting on \( \mathcal{H} \) is defined to be \( F = \eta_+ + \eta_- \) in which \( \eta_\pm = T^\pm \sigma_\pm, \sigma_\pm = (\sigma_1 \pm i\sigma_2)/2 \) and \( \sigma_i, i = 1, 2, 3 \) are Pauli matrices [7]. Note that \( \eta_\pm \) fulfil Clifford algebra relation on 2D-Euclidean space \( \eta_\pm \eta_\pm = 0, \{\eta_\pm, \eta_\mp\} = 1 \); accordingly, \( F^2 = 1 \), s.t.(\( \mathcal{H}, F \)) forms a Fredholm module [8]. The fundamental non-commutativity in this formalism is \( \eta_\pm f = (T^\pm f)\eta_\pm \). It is proved in [7] that Connes’ distance on \( \mathbb{Z}_N \) defined by \( d_F(x, y) = \sup\{|f(x) - f(y)| : \| [F, f] \| \leq 1\}, \forall x, y \in \mathbb{Z}_N \) is just the conventional linear(Euclidean)-distance on \( \mathbb{Z}_N \): \( d(x, y) = \min\{|x - y|, N - |x - y|\} \).
Dirac operator on $\mathbb{Z}_N$ is $F$ twisted with a link-variable: $F(\omega) = \omega^\dagger \eta_+ + \eta_- \omega$ in which $\omega$ is a $\text{End}_C(\mathcal{H}_c)$-valued function on $\mathbb{Z}_N$ and $\mathcal{H}_c$ is an internal Hilbert space. The triple $(\mathcal{A}(\mathbb{Z}_N), \tilde{H}, F(\omega))$ becomes a $K$-cycle where $\tilde{H} = \mathcal{H} \otimes \mathcal{H}_c$. A gauge transformation $u$ is a $U(\mathcal{H}_c)$-valued function on $\mathbb{Z}_N$; $T^- \omega, \omega^\dagger T^+ \omega$ play the role of $U(\mathcal{H}_c)$ parallel transports, providing that $\omega \to (T^+ u) \omega u^\dagger$. Below only 1-dimensional case $\mathcal{H}_c = \mathbb{C}$ will be considered, hence $\omega \in \mathcal{A}(\mathbb{Z}_N)$. Subsequently, $\omega = \rho e^{i \theta}$ where $\rho, \theta$ are real functions, $\rho(x) \geq 0$ and $\omega^\dagger = \overline{\omega}$. We argued at the end of [2] that $d_{F(\omega)}(x, x + k) = \min \{\rho(x)^{-1} + \rho(x + 1)^{-1} + \ldots + \rho(x + k - 1)^{-1}, \rho(x + k)^{-1} + \rho(x + k + 1)^{-1} + \ldots + \rho(x + N - 1)^{-1}\}$ for all $x, k \in \mathbb{Z}_N$. Therefore, metric on $\mathbb{Z}_N$ is modified by the strength of $\omega$ in the sense that $\rho^{-1}$ provides a varying lattice spacing. This point can be illustrated more clearly by some special examples. 1) $\rho(x) = \rho_0 > 0$, then resulting metric differs from the “free” one by a lattice constant $1/\rho_0$; 2) $\rho(0) = 0$, then $d_{F(\omega)}(0, 1) = \infty$, which can be interpreted that the points $x = 0$ and $x = 1$ are disconnected; 3) $\rho(0) \to +\infty$, then $d_{F(\omega)}(0, 1) \to 0$, which is interpreted as a “black hole” by M. Hale in [4]. In the next section, dynamics of $\omega$ will be considered; cases 1) and 2) will be shown to emerge from classical solutions to the equations of motion for $\omega$. We deliver two identities at the end of this section

$$F(\omega)^2 = T^-(\omega^\dagger \omega) \eta_- \sigma_+ + (\omega^\dagger \omega) \eta_+ \eta_- = \rule{1\text{cm}}{}$$

$$F(\omega) \wedge F(\omega) := T^-(\omega^\dagger \omega) \eta_- \wedge \eta_+ + (\omega^\dagger \omega) \eta_+ \wedge \eta_- = \frac{1}{2}(T^-(\rho^2) - \rho^2)[\sigma_-, \sigma_+] = -\frac{1}{2} \partial^-(\rho^2) \sigma_3$$

where $\partial^\pm f := T^\pm f - f$.

### III Vacuum Solutions: Dynamics of Dirac Operator

Three action functionals containing only $\omega$ will be considered below. What we mainly concern is whether there be non-trivial vacuum solutions in the corresponding equations of motion. By a “non-trivial vacuum”, we mean that translation invariance of $\mathbb{Z}_N$ is broken by this solution.

#### III.1 Trivial Cases: $S[\omega] = Tr(F(\omega)^{2k}), k = 1, 2, ...$

Notice Eq.(1), $S[\omega] = 2 \sum \rho^{2k}$. This action admits only 0-solution obviously.
III.2 Trivial Cases: \( S[\omega] = Tr((F(\omega) \wedge F(\omega))(F(\omega) \wedge F(\omega))) \)

By Eq.(2), \( S[\omega] = \frac{1}{2} \sum (\partial^- (\rho^2))^2 \). Equation of motion is deduced by \( \delta_\omega S[\omega] = 0 \)

\[
\rho(x)(2\rho(x)^2 - \rho(x + 1)^2 - \rho(x - 1)^2) = 0, \forall x \in \mathbb{Z}_N
\]

If \( \rho(x) \neq 0, \forall x \in \mathbb{Z} \), let \( \phi = \rho^2 \), Eq.(3) takes on the form

\[
\partial^+ \partial^- \phi = 0
\]

which is a discretized harmonic equation \( \Delta \phi = 0 \) on \( S^1 \). Eq.(4) admits only constant solution \( \rho(x) = \rho_0 \), which can be understood schematically by the extremal value principle in commutative harmonic analysis [10]. The on-shell metric satisfies \( d_F(\omega)(,) = \frac{1}{\rho_0} d_F(,) \) which corresponds the case 1) in the last section, namely that lattice constant is modified from 1 to \( 1/\rho_0 \). Else if there is one \( x_0 \) such that \( \rho(x_0) = 0 \), then the only consistent solution is \( \rho(x) = 0 \) for all \( x \).

III.3 Nontrivial Case

Now consider

\[
S[\omega] = \frac{1}{2} Tr((F(\omega) \wedge F(\omega))(F(\omega) \wedge F(\omega))) + \frac{\alpha}{4} F(\omega)^4 - \frac{\beta}{2} F(\omega)^2
\]

in which coupling constants \( \alpha, \beta \) are real numbers and are required to be not equal to zero at the same time.

One can check that \( S[\omega] = \sum \left( \frac{1}{4} (\partial^- (\rho^2))^2 + \frac{\alpha}{4} \rho^4 - \frac{\beta}{2} \rho^2 \right) \). The equation of motion is given by

\[
\rho(2t \rho^2 - T^+ (\rho^2) - T^- (\rho^2) - \beta) = 0
\]

where \( t := (2 + \alpha)/2 \).

III.3.1 Non-singular Case: \( \rho(x) > 0, \forall x \in \mathbb{Z}_N \)

Remember the definition of \( \phi \), then Eq.(5) changes form as

\[
- \phi(x - 1) + 2t \phi(x) - \phi(x + 1) = \beta, \forall x \in \mathbb{Z}_N
\]

The cyclic symmetry in Eq.(6) \( \phi(x) \rightarrow \phi(x + 1) \) implies that \( \phi(x) = \phi_0, \forall x \in \mathbb{Z}_N \) in which \( \phi_0 = \frac{\beta}{2t - 2} = \frac{\beta}{\alpha} \).

Note that if \( \alpha = 0, \beta \neq 0 \), no solution exists. Upon this solution as a background, metric fulfills relation

\[
d_{F(\omega)}(,) = \sqrt{\frac{2}{\beta}} d_{F(,)}.
\]
### III.3.2 Singular Case

The remainder of this section will be devoted to one most interesting situation in which, without losing generality, \( \rho(N-1) = 0, \rho(x) > 0, x = 0, 1, \ldots N - 2 \). If we find out a solution to this case, then this solution breaks translation invariance, hence being a nontrivial vacuum. Some matrix algebra has to be prepared here. Introduce a matrix sequence \( \{ M_n(t) : n = 1, 2, \ldots \} \) in which

\[
M_n(t) := \begin{pmatrix}
  2t & -1 & 0 & 0 & \ldots & 0 & 0 & 0 \\
  -1 & 2t & -1 & 0 & \ldots & 0 & 0 & 0 \\
  0 & -1 & 2t & -1 & \ldots & 0 & 0 & 0 \\
  \vdots & & & & & & & \\
  0 & 0 & 0 & 0 & \ldots & -1 & 2t & -1 \\
  0 & 0 & 0 & 0 & \ldots & 0 & -1 & 2t \\
\end{pmatrix}
\]

is a \( n \times n \) matrix, and define

\[
U_n(t) = \det(M_n(t))
\]  

(8)

One can prove this iterative relation easily

\[
U_0(t) := 1, U_1(t) = t, U_n(t) = 2tU_{n-1}(t) - U_{n-2}(t), n = 2, 3, \ldots
\]

(9)

Eq. (8) shows that \( U_n(t) \) are \textit{Chebyshev’s polynomials of the second kind}, hence

\[
U_n(t) = \frac{z_{+}^{n+1} - z_{-}^{n+1}}{2\sqrt{t^2 - 1}}[11].
\]

So (8) provides Chebyshev’s polynomials with another interpretation. Note that all roots of \( U_n(t) \) are real and lie in \((-1, 1)\) and that \( U_n(t) > 0 \), if \( t > 1, n = 0, 1, 2, \ldots \). We set \( t > 1 \), i.e. \( \alpha > 0 \) from now on.

Now let \( \Phi = (\phi(0), \phi(1), \ldots, \phi(N-2))^T, 1_V = (1, 1, \ldots, 1)^T, \) then equation of motion (6) can be written as

\[
M_{N-1}(t)\Phi = \beta 1_V. \quad \text{Assume } \beta \neq 0 \text{ and scale } \phi = \beta v, \Phi = \beta V, \text{ then}
\]

\[
M_{N-1}(t)V = 1_V
\]

(10)

Introduce notations \( f_{i,j}(t) = \frac{U_i(t)}{U_j(t)} \), \( \Sigma_n(t) = \sum_{j=0}^{n} U_j(t) \), \( \psi_n = \frac{\Sigma_n(t)}{U_{n+1}(t)} \). Formal solution to Eq.(10) is

\[
v(x) = \sum_{y=0}^{N-2} f_{x,x+y}(t) \psi_{x+y}(t), x = 0, 1, \ldots, N - 2
\]

(11)
Since we choose \( t > 1 \), there is no singularity in \( v(x) \). If \( \beta > 0 \), due to the positivity of \( U_n(t) \) when \( t > 1(\alpha > 0) \), \( \phi(x) > 0, \forall x = 0, 1, ..., N - 2 \), i.e. being physically acceptable. Solutions for \( N = 3, 4, 5, 6 \) are listed in Appendix A.

IV Discussions

The geometric interpretation of the solutions in Subsect. III.3.2 is that when coupling \( \alpha > 0 \) and \( \beta > 0 \), there are nontrivial vacuum appearing and that the metrics appear to be

\[
d_{F(\omega)}(x, y) = \beta^{-\frac{1}{2}}(v(x)^{-\frac{1}{2}} + v(x + 1)^{-\frac{1}{2}} + \ldots + v(y - 1)^{-\frac{1}{2}})
\]

for all \( x, y = 0, 1, ..., N - 2, x < y \). Moreover, this statement is valid in the limit \( N \to \infty \).

Interesting topics along this line are interaction between link variable \( \omega \) and matter fields, “black hole” solutions, quantization, \( dim(\mathcal{H}_c) > 1 \) case and higher dimension cases. Work on these aspects is in proceeding.

Acknowledgements

This work was supported by Climb-Up (Pan Deng) Project of Department of Science and Technology in China, Chinese National Science Foundation and Doctoral Programme Foundation of Institution of Higher Education in China. We are very grateful to Dr. B. Feng in MIT for that the general method to discuss Eq.(9) is showed by Dr. Feng to us, and to Prof. S. Majid for introducing his work to us.

A Solutions to Eq.(10) for \( N=3,4,5,6 \)

\[
N = 3 : v(0) = v(1) = \frac{1}{2t - 1}
\]

\[
N = 4 : v(0) = v(2) = \frac{2t + 1}{4t^2 - 2}; v(1) = \frac{t + 1}{2t^2 - 1}
\]

\[
N = 5 : v(0) = v(3) = \frac{2t}{4t^2 - 2t - 1}; v(1) = v(2) = \frac{2t + 1}{4t^2 - 2t - 1}
\]

\[
N = 6 : v(0) = v(4) = \frac{4t^2 + 2t - 1}{2t(4t^2 - 3)}; v(1) = v(3) = \frac{2t + 2}{4t^2 - 3}; v(2) = \frac{4t^2 + 4t + 1}{2t(4t^2 - 3)}
\]
