Global Existence for the N Body Euler–Poisson System

SHRISH PARMESHWAR

Communicated by N. Masmoudi

Abstract

In this paper we investigate the problem of multiple expanding Newtonian stars that interact via their gravitational effect on each other. It is clear physically that if two stars at rest are separated initially, and start expanding as well as moving according to the laws of Newtonian gravity, they may eventually collide. Thus, one can ask whether each star can be given an initial position and velocity such that they can keep expanding without touching. We show that even with gravitational interaction between the bodies, a large class of initial positions and velocities give global-in-time solutions to the N Body Euler–Poisson system. To do this we use scaling mechanisms present in the compressible Euler system, shown in Parmeshwar (Quart Appl Math 79(2):273–334, 2021), gaining advantageous time weights and smallness in our estimates under the specific form of the Lagrangian flow maps, and assumption of small mass for each star, represented by a parameter \( \delta \). This is combined with a careful analysis of how the gravitational interaction between stars affects their dynamics.

1. Introduction

The compressible Euler–Poisson system for an inviscid, isentropic, ideal gas, acting under the influence of its own gravity, in its most basic form, is given by

\[
\begin{align*}
\partial_t \rho + \nabla \cdot (\rho u) &= 0, \\
\rho (\partial_t u + u \cdot \nabla) u + \nabla p + \rho \nabla \phi &= 0, \\
\Delta \phi &= 4\pi \rho, \\
\lim_{|x| \to \infty} \phi(t, x) &= 0,
\end{align*}
\]

where \( \rho, u, p, \) and \( \phi \) are the fluid density, velocity, pressure, and gravitational potential respectively. Newton’s gravitational constant \( G \) will be set to 1 here and hereafter in this work.
Remark 1. Investigating the properties of stars modelled as bodies of fluids is a classical problem in astrophysics, with a long history. In the case of one body of incompressible fluid moving under its own gravity, equilibrium states have been studied by the likes of Newton, Maclaurin, Jacobi, Poincaré, and others. See, for example, [8] for a summary of these results, and further context regarding this problem.

Remark 2. Note that if instead we had $\Delta \phi = -4\pi \rho$, $\phi$ would be referred to as the electrostatic potential, and the above would be a toy model of a plasma instead of a Newtonian star. See [27,28] for more details on the mathematical theory of plasmas.

In addition to the basic system (1)–(3), we will always work with a polytropic equation of state between the pressure $p$ and the density $\rho$,

$$p(\rho) = \rho^\gamma,$$

for some $\gamma > 1$, the adiabatic index. The system (1)–(4) is one of the most fundamental and commonly used models of a Newtonian star ([4,7,81]). In addition, the equation of state guarantees the system is not underdetermined. A famous class of solutions to (1)–(4) are the so called Lane-Emden stars, obtained by looking for radially symmetric, time independent density profiles, and vanishing velocity:

$$(\rho(t, x), u(t, x)) = (\bar{\rho}(r), 0).$$

In the range $6/5 < \gamma < 2$, it is known that there always exists a solution with finite mass and compact support, whilst for $\gamma = 6/5$ there exists a solution with finite mass and infinite support ([4,7,37,81]). The fundamental problem of establishing linear or nonlinear stability for these solutions has also been investigated. LIN [48] established linear instability for $\gamma \in (1, 4/3)$, and linear stability for $\gamma \in [4/3, 2)$. It is also known that at $\gamma = 4/3$, the Lane-Emden star solution is nonlinearly unstable ([14,24,30,37,57,66]). Jang [36,37] showed that for $\gamma \in [6/5, 4/3)$, the Lane-Emden stars are nonlinearly unstable, whilst stability results for the range $(4/3, 2)$ conditional on the existence of solutions close to the stationary ones have been shown in [55,66].

In the mass critical case of $\gamma = 4/3$, sc Goldreich and WEBER [24] exhibited another special class of spherically symmetric solutions that could either expand indefinitely, or collapse in finite time. These solutions are self similar with respect to the same rescaling under which 4/3 is the mass critical exponent, and have 0 energy. In further works for the same value of $\gamma$, MAKINO [57], (see also FU and LIN [23]) constructed related solutions that also expand or collapse. Hadžić and Jang [30] showed the nonlinear stability of these solutions in the expanding case under spherically symmetric perturbations. Corresponding solutions for the nonisentropic case, and spatial dimensions $\geq 3$, have been constructed by Deng, Xiang, and Yang [15].

Another important family of solutions, that of axisymmetric rotating stars in equilibrium, has long been a subject of interest, with efforts to construct such stars beginning in the astrophysics community in the early 20th century, see [6,47,63,78].
Auchmuty and Beals [2,3] rigorously constructed solutions using a variational method. Given a prescribed angular velocity, or angular momentum per unit mass, they found axisymmetric densities \( \rho \) that satisfied the time independent version of the Euler–Poisson system (1)–(3), for \( \gamma > 4/3 \) (amongst other, non polytropic equations of state). Auchmuty [1] showed the existence of equilibrium rotating solutions in the incompressible case using these methods. Li [46] also used these variational techniques to find related solutions with constant angular velocity, a case which was excluded by the assumptions made in the work of Auchmuty and Beals. McCann [61] has shown that one can construct rotating binary star solutions in equilibrium using variational principles. Results have also been established on the shape of the support of these solutions, see [5,9,10,20,21]. For further works in the variational framework, see [22,49,54,55,79,80], and references within, as well as work by Federbush, Luo, and Smoller [19], in the case of magnetic stars.

Jang and Makino [42,43], and Strauss and Wu [76,77], who built on techniques first employed by Lichtenstein [47] and Heilig [34], have also constructed axisymmetric rotating solutions, by making use of the Implicit Function Theorem. This method allows for solutions with \( \gamma \leq 4/3 \), and in the works by Strauss and Wu, they in fact construct a continuous family of solutions parameterised by the prescribed angular velocity. In addition, Jang, Strauss, and Wu [44] used these techniques to construct a rotating magnetic star.

1.1. The Euler–Poisson system for \( N \) stars

The model we work with describes \( N \) Newtonian stars moving under both the influence of their own gravity, and that of the other stars, in the free boundary setting. Let \( N \geq 2 \) be a natural number. For each \( \kappa = 1, 2, \ldots, N \), we have

\[
\begin{align*}
\frac{\partial}{\partial t} \rho_{\kappa} + \nabla \cdot (\rho_{\kappa} u_{\kappa}) &= 0 \quad \text{in } \Omega_{\kappa}(t), \\
\rho_{\kappa} \left( \frac{\partial}{\partial t} u_{\kappa} + \nabla \phi \right) + \nabla p_{\kappa} + \rho_{\kappa} \nabla \phi &= 0 \quad \text{in } \Omega_{\kappa}(t), \\
p_{\kappa} &= 0 \quad \text{on } \partial \Omega_{\kappa}(t), \\
\Delta \phi &= 4\pi \rho, \quad \lim_{|x| \to \infty} \phi(t, x) = 0 \quad \text{on } \mathbb{R}^3, \\
V(\partial \Omega_{\kappa}(t)) &= u_{\kappa} \cdot n_{\kappa} \quad \text{on } \partial \Omega_{\kappa}(t), \\
(\rho_{\kappa}, u_{\kappa}) &= (\bar{\rho}_{\kappa}, \bar{u}_{\kappa}) \quad \text{in } \Omega_{\kappa}(0).
\end{align*}
\]

Remark 3. Here \( \kappa \) is introduced as an index variable ranging from 1 to \( N \). Throughout this work, indexing the star bodies will be the one and only use of \( \kappa \), and conversely, indexing of the separate stars will only be done with \( \kappa \). In particular there will be no summation convention over \( \kappa \).

Analogously to (1)–(3), the \( \rho_{\kappa}, u_{\kappa}, \) and \( p_{\kappa} \) are the densities, velocities, and pressures for each separate star. As mentioned in (4), we have a polytropic equation of state for each \( \kappa \) given by

\[
p_{\kappa}(\rho_{\kappa}) = \rho_{\kappa}^{\gamma_{\kappa}},
\]
where \( \gamma > 1 \) is constant, and the same for each \( \kappa \).

**Remark 4.** It is not crucial for each \( \gamma \) to be the same for each equation of state, that is \( \gamma \) could depend on \( \kappa \). If this dependence was present, the only changes would be during the proofs of estimates in Sections 7, 8, 9, and 10, where one would have to keep track of the dependence on \( \gamma_k \) of the powers of \( \delta \) (a parameter used to guarantee small initial mass of each star, introduced in (69)) in order to close our final estimates. However, in reality this boils down to making sure that

\[
\max_{\kappa \in \{1, \ldots, N\}} \delta^{\frac{1}{N_k - T}} \leq C \delta
\]

for some fixed constant \( C \). As \( \kappa \) ranges over a finite index set, and we will be able to make \( \delta \) as small as we want, this will always be possible regardless of what dependence on \( \kappa \) each \( \gamma_k \) has (as long as they all are of the form \( 1 + n^{-1}, n \in \mathbb{Z}_{\geq 2} \) or in \( (1, 14/13) \) for separate, technical reasons explained already in [32]). Thus to simplify our analysis when doing the final estimates, we assume that all the \( \gamma \) are the same for each \( \kappa \).

Comparing (1)–(4) to (6)–(12), we see that in the latter system, for each fixed \( t \), the continuity and momentum equations for each \( \kappa \) are only required to hold on the support of \( \rho_k(t, \cdot) \), namely \( \Omega_k(t) \), instead of on all of \( \mathbb{R}^3 \) as in the former system. In addition, the support, and therefore its boundary is now a dynamic object whose evolution we track in our framework, making this model a vacuum free boundary problem.

The \( \rho_k \) are non-negative functions \( \rho_k : [0, \infty) \times \mathbb{R}^3 \to \mathbb{R}_{\geq 0} \), with supports \( \text{supp} \rho_k(t, \cdot) = \Omega_k(t) \). The boundary of \( \Omega_k(t) \) is given by \( \partial \Omega_k(t) \). We also have the initial domains and their boundaries

\[
\Omega_k := \Omega_k(0), \quad \partial \Omega_k := \partial \Omega_k(0).
\]

Since we are looking at stars that are separated from each other initially, physically we must have that the \( \Omega_k \) are mutually disjoint and compact. The cumulative density function \( \rho : [0, \infty) \times \mathbb{R}^3 \to \mathbb{R}_{\geq 0} \) is defined by

\[
\rho = \sum_{\kappa=1}^{N} \rho_k,
\]

and \( \phi \) is the cumulative gravitational potential. For each fixed \( t \), the domain of the velocity field at time \( t \) is given by the support of the density at time \( t \):

\[
u_k(t, \cdot) : \Omega_k(t) \to \mathbb{R}^3,
\]

\[
x \mapsto u_k(t, x).
\]

Finally, the quantity \( V(\partial \Omega_k(t)) \) is the outward normal velocity of \( \partial \Omega_k(t) \) and \( n_k \) is the outward unit normal on \( \partial \Omega_k(t) \).
To construct a robust well-posedness theory for the moving vacuum boundary Euler–Poisson system, it is crucial to include the physical vacuum boundary condition. For each $\kappa$, the speed of sound $c_\kappa$ is given by

$$c^2_\kappa = \frac{dp_\kappa}{d\rho_\kappa} = \gamma \rho_\kappa^{\gamma-1}, \quad \hat{c}^2_\kappa(x) = c^2_\kappa(0, x). \quad (16)$$

Then the physical vacuum boundary condition reads as

$$-\infty < \frac{\partial \hat{c}^2_\kappa}{\partial \hat{n}_\kappa} \bigg|_{\partial \Omega_\kappa} < 0, \quad (17)$$

where $\hat{n}_\kappa$ is the outward unit normal on $\partial \Omega_\kappa$. Condition (17) implies that for some constant $C$

$$\frac{1}{C} \text{dist}(x, \partial \Omega_\kappa) \leq \hat{c}^2_\kappa(x) \leq C \text{dist}(x, \partial \Omega_\kappa), \quad (18)$$

which in turn implies that $\hat{c}_\kappa$ is only Hölder continuous of exponent $1/2$ at the boundary $\Omega_\kappa$. We note that as well as being a key component for the local theory of our system, the physical vacuum condition also naturally occurs in Lane-Emden stars [37]. Liu [50] gave an argument suggesting that the physical vacuum condition was natural in the context of the Euler system with damping. In general, the physical vacuum condition, and the role it plays in understanding the interaction of fluids with vacuum regions has been a subject of great interest, see [11–13,31,32,38–41,51–53,56,71].

When we view the problem on $\mathbb{R}^3$, any sufficiently regular nontrivial spherically symmetric solution with compact initial data has a finite time of existence [58,59], with the same holding for any nontrivial solution for the Euler system without gravitation [60]. Results on singularity formulation for the Euler system have also been established by Sideris [72]. The solutions in [58,59] cannot satisfy the physical vacuum boundary condition (17), as the initial speed of sound $\hat{c}$ is continuously differentiable on the boundary.

In the case of the physical vacuum free boundary, well-posedness theories for the compressible Euler system were developed in Lagrangian variables by Coutand and Skholler [13], and Jang and Masmoudi [41] independently. In our work, we adapt the techniques of Jang and Masmoudi. This theory is readily adapted to the Euler–Poisson system for the case $N = 1$ as the potential term $\rho \nabla \phi$ is lower order, with respect to derivative count, to the top order pressure term $\nabla p$. We shall see in Appendix A that the local-in-time theory for $N \geq 2$ does not require much adjustment in the theory either. Recently, Ifrim and Tataru developed a well-posedness theory for the same system in Eulerian variables [35], with Disconzi, Ifrim, and Tataru then developing a local-well-posedness theory for the physical vacuum free boundary Relativistic Euler equations in Eulerian variables [16].

It is natural to look for expanding solutions to the Euler–Poisson system. Indeed, it has been shown that global-in-time solutions to the Euler system must have supports whose diameters grow at least linearly in time, with the same being true for solutions to the Euler–Poisson system with positive energy when $\gamma \geq 4/3$, see
Note that equilibrium solutions like the ones mentioned in the introduction are not considered in the class of time dependent solutions.

In the vacuum free boundary setting for the Euler system without gravitation, a finite parameter family of expanding global-in-time solutions has been found by Sideris [73, 74], relying on an affine ansatz on the Lagrangian flow map, allowing him to reduce the problem to one of solving a system of ODEs. The corresponding solutions are a finite dimensional family of compactly supported, expanding stars. Using an affine ansatz to construct solutions for compressible fluid flow is a technique that goes back to Ovsiannikov [64] and Dyson [17]. Hadžić and Jang [31] showed nonlinear stability of the solutions constructed in [74] for the range $\gamma \in (1, 5/3)$, after which Sideris and Shkoller [69] established the corresponding result for $\gamma > 5/3$. In the nonisentropic case, nonlinear stability of the Sideris solutions was established by Rickard, Hadžić, and Jang [67].

In addition, Hadžić and Jang [32] also showed that small perturbations of the Sideris affine solutions give rise to solutions to the vacuum free boundary Euler–Poisson system, utilising a scaling structure in the system that allowed them to construct these solutions under the assumption of small densities. In general their methods require $\gamma \in (1, 5/3)$. In this range, the gravitational potential terms are subcritical with respect to the pressure term, meaning that the pressure term will dominate the dynamics of the star. This is part of what allowed them to perturb solutions of the Euler system to find their solutions of the Euler–Poisson system. More specifically, their range of $\gamma$ was restricted to $\{1 + \frac{1}{n} | n \in \mathbb{Z} \geq 2\} \cup (1, 14/13)$. Note that these restrictions, apart from being a subset of $(1, 5/3)$, are largely technical and related to estimating the gravitational potential terms.

The author, along with Hadžić and Jang [65], then showed that one can construct a family of global-in-time expanding solutions to the vacuum free boundary Euler and Euler–Poisson systems without appealing to an affine type ODE reduction. The main tool was utilising a scaling structure in the nonlinearity of the momentum equation that produced a stabilising effect. This, as well as the scaling exhibited in [32], was used to construct solutions with small densities. Analogously to [32], the range of $\gamma$ for the Euler–Poisson system is $\{1 + \frac{1}{n} | n \in \mathbb{Z} \geq 2\} \cup (1, 14/13)$. Despite the smallness condition, the initial densities in [65] have a wide class of possible profiles, whereas those associated with the solutions exhibited in [74] have a very specific form.

In the absence of a free boundary, global-in-time expanding solutions have been found by Serre [70], Grassin [25], and Rozanova [68]. Serre found solutions by perturbing around linear velocity profiles, an idea which Grassin generalised. Rozanova showed the existence of related solutions without the small density assumption made by Grassin.

With the polytropic equations of state in (12), our system becomes, for $\kappa = 1, 2, \ldots, N$,

\begin{align}
\partial_t \rho_k + \nabla \cdot (\rho_k u_k) &= 0 \quad \text{in } \Omega_k(t), \\
\rho_k (\partial_t + u_k \cdot \nabla) u_k + \nabla (\rho_k^\gamma) + \rho_k \nabla \phi &= 0 \quad \text{in } \Omega_k(t), \\
\rho_k &= 0 \quad \text{on } \partial \Omega_k(t).
\end{align}
\[ \Delta \phi = 4\pi \rho, \quad \lim_{|x| \to \infty} \phi(t, x) = 0 \quad \text{on } \mathbb{R}^3, \quad (22) \]

\[ \mathcal{V} (\partial \Omega_k(t)) = u_k \cdot n_k \quad \text{on } \partial \Omega_k(t), \quad (23) \]

\[ (\rho_k, u_k) = (\dot{\rho}_k, \dot{u}_k) \quad \text{in } \Omega_k. \quad (24) \]

We shall refer to the system (19)–(24) with the physical vacuum condition (17) as \( \text{EP}(N, \gamma) \). If we set

\[ w_k(x) := \dot{\rho}_k^{\gamma-1}(x). \quad (25) \]

then

\[ \frac{1}{C} \text{dist}(x, \partial \Omega_k) \leq w_k(x) \leq C \text{dist}(x, \partial \Omega_k) \quad (26) \]

in the vicinity of the initial vacuum boundary \( \partial \Omega_k \). The quantity \( \sum_{k=1}^N w_k \) is proportional to the enthalpy of the system and the \( \{w_k | k = 1, 2, \ldots, N\} \) will play a very important role in our analysis. For future simplicity, define

\[ \alpha = \frac{1}{\gamma - 1}, \quad (27) \]

so that \( \dot{\rho}_k = w_k^\alpha \).

By contrast to the classical \( N \) Body problem, the stars described by our system are subjected to tidal forces which deform the geometry of their supports, and hence they can not be idealised as point particles. The classical problem consists of looking for solutions to the system of \( N \) point particles interacting with each other via Newtonian gravity:

\[ \frac{d^2 x_i}{dt^2} = - \sum_{1 \leq i, j \leq N, i \neq j} m_i \frac{x_i - x_j}{|x_i - x_j|^3} \quad x_i(0) = \bar{x}_i, \quad \dot{x}_i(0) = v_i. \quad (28) \]

Here the \( x_i(t) \) are the particle positions at time \( t \), the \( m_i \) are the particle masses, \( \bar{x}_i \) are their initial positions, and \( v_i \) are their initial velocities. Much like the subject of stellar dynamics, the \( N \) body problem has a long and rich history; for more on the history and context, see [33,75] and references within.

In our context, as mentioned previously, McCann [61] exhibited solutions to the stationary compressible Euler–Poisson system that corresponded to a rotating binary star system. Miao and Shahshahani [62] showed that in the case of the 2 body problem for the incompressible free boundary Euler–Poisson system, one can start with initial configurations that would correspond to hyperbolic orbit in the point particle case, and obtain bounded orbits. The reason is that the fluid bodies will naturally deform due to their gravitational effects on each other, and this results in a loss of energy.

In the classical \( N \) Body problem (28), one can ask what happens to the dynamics of each particle if we start them far away from each other (in some suitable sense), and also point their initial velocities away from each other. We might expect that if the initial distances are large enough, with initial velocities pointing in suitable
directions, their dynamics will essentially decouple, and each will travel on a path of constant velocity up to small error. We will show in our work that this type of initial configuration can lead to global-in-time solutions even in the case of the $N$ Body of Euler–Poisson system.

Explicitly, we exhibit an open set (in a suitable topology) of initial positions and velocities that lead to global-in-time solutions of $\text{EP}(N, \gamma)$, with each star asymptotically behaving like an expanding star moving with constant velocity. This is further discussed in Sections 3.1, 6.1. Now we state a rough version of our theorem.

**Theorem 1.** (Main result: informal statement) Let $\gamma = 1 + \frac{1}{n}$ for $n \in \mathbb{Z}_{\geq 2}$ or $\gamma \in (1, 14/13)$. Then there exist open sets of initial positions and velocities for each star in the free boundary $N$-body compressible Euler–Poisson system $\text{EP}(N, \gamma)$ which lead to global-in-time solutions.

**Remark 5.** The restriction of possible values of $\gamma$ in our work is for the same reasons as in [32, 65], discussed previously in this introduction.

The plan of the paper is as follows. In Section 2 we formulate our problem in Lagrangian variables, a technique commonly used to study the physical vacuum free boundary compressible Euler(-Poisson) system. In Section 3, we discuss the properties of scaling in the Euler–Poisson system, and how we use these properties to find global-in-time solutions. In Section 4, we fix general notation, and in Section 5 we define our energy spaces and higher order energy and curl functions. In Section 6 we state our main result precisely, and list our a priori assumptions. Sections 7, 8, and 9 are devoted to estimates of the gravitational potential, curl estimates, and energy estimates respectively. Finally, in Section 10, we prove our main result, Theorem 3.

### 2. Lagrangian Formulation

For simplicity, we will assume that the initial domains $\Omega_\kappa$ are closed balls of radius 1 with centres $\bar{x}_\kappa$. We introduce a reference domain

$$\Omega := B_1,$$  \hfill (29)

where $B_1$ is the closed unit ball centred at 0 in $\mathbb{R}^3$. For $\kappa = 1, 2, \ldots, N$, it is clear that $\Omega_\kappa = \Omega + \bar{x}_\kappa$.

**Remark 6.** The techniques we use to construct global-in-time solutions in this paper work equally well when each $\Omega_\kappa$ is a diffeomorphism of a translate of the closed unit ball, close enough to the identity in some norm, with each translation such that the distance between every pair of domains is sufficiently large.

Following [13, 41], we utilise Lagrangian coordinates to transform the problem of studying to the free boundary problem $\text{EP}(N, \gamma)$ in to one of studying a fixed
boundary problem. Define, for each \( \kappa = 1, 2, \ldots, N \), the Lagrangian flow map \( \eta_\kappa \) by
\[
\eta_\kappa : I \times \Omega \to \Omega_\kappa(t)
\]
\[
(t, x) \mapsto \eta_\kappa(t, x),
\]
which solves the ODE
\[
\partial_t \eta_\kappa(t, x) = u_\kappa(t, \eta_\kappa(t, x)), \quad t \in I,
\]
\[
\dot{\eta}_\kappa(x) = \eta_\kappa(0, x) = x + \bar{x}_\kappa.
\]
Here \( I \) is some time interval. Let
\[
v_\kappa(t, x) = u_\kappa(t, \eta_\kappa(t, x)),
\]
\[
f_\kappa(t, x) = \rho_\kappa(t, \eta_\kappa(t, x)),
\]
\[\mathcal{M}[\kappa] = \nabla \eta_\kappa,\]
\[\mathcal{A}[\kappa] = (\mathcal{M}[\kappa])^{-1},\]
\[\mathcal{J}_\kappa = \det \mathcal{M}[\kappa],\]
\[a[\kappa] = \mathcal{J}_\kappa \mathcal{A}[\kappa],\]
\[\psi_\kappa(t, x) = \phi(t, \eta_\kappa(x, t)).\]

We have the following differentiation formulae for \( \mathcal{A} \) and \( \mathcal{J} \):
\[
\partial_j a[\kappa]_i^j = 0.
\]

For each \( \kappa = 1, 2, \ldots, N \), pulling the continuity and momentum equations (19) and (20) back via the flow map \( \eta_\kappa \) gives us, for \( i = 1, 2, 3 \),
\[
\partial_t f_\kappa + f_\kappa \mathcal{A}[\kappa]_i^j \partial_j v_\kappa^i = 0 \quad \text{in } I \times \Omega,
\]
\[
\partial_i v_\kappa^i + \mathcal{A}[\kappa]_i^j \partial_j (f_\kappa^j) + f_\kappa \mathcal{A}[\kappa]_i^j \partial_j \psi_\kappa = 0 \quad \text{in } I \times \Omega.
\]

Then, applying the formula for \( \mathcal{J} \) in (39), from (41) we obtain
\[
f_\kappa(t, x) = \rho_\kappa(t, \eta_\kappa(t, x)) = \rho_\kappa(\tilde{\eta}_\kappa(x)) \mathcal{J}_\kappa^{-1}.
\]

Finally, applying (40), (43) to (42), and recalling from (31) that \( \partial_t \eta_\kappa = v_\kappa \) our system becomes, for \( \kappa = 1, 2, \ldots, N \), and \( i = 1, 2, 3 \):
\[
\tilde{w}_\kappa^\alpha \partial_{ij} \eta_\kappa^i + \partial_k \left( \tilde{w}_\kappa^{1+\alpha} A[\kappa]^k_j \mathcal{J}_\kappa^{-1/\alpha} \right) + \tilde{w}_k^\alpha A[\kappa]^k_i \partial_k \psi_\kappa = 0 \quad \text{in } I \times \Omega,
\]
\[
(v_\kappa(t, x), \eta_\kappa(t, x)) = (\tilde{u}_\kappa(\tilde{\eta}_\kappa(x)), \tilde{\eta}_\kappa) \quad \text{in } \{ t = 0 \} \times \Omega,
\]
\[
\tilde{w}_\kappa = 0 \quad \text{on } \partial \Omega.
\]

where, recalling \( w_\kappa \) defined in (25), we define
\[
\tilde{w}_\kappa(x) = \rho_\kappa(\tilde{\eta}_\kappa(x))^{-1} = w_\kappa(x + \bar{x}_\kappa).
\]

For a more detailed derivation of the system (44)–(46), see, for example [41].
3. Rescaling

3.1. Flow map

In this section we introduce our ansatz for $\eta_\kappa$. However, we first give a motivation for the form of our ansatz. In [65] the author alongside Hadžić and Jang found that in the case of $N = 1$, solutions of the form

$$\eta(t, x) = (t + 1)(x + \theta(\log (1 + t), x))$$  \hspace{1cm} (48)

for the Euler and Euler–Poisson systems were global-in-time solutions for small enough $\theta$ (with size measured in a suitable function space), as well as small enough initial density. The suggested form of $\eta$ in (48) is exactly what allows us to take advantage of the nonlinear scaling structure in the Euler, and Euler–Poisson systems. However, we can also view it as encoding the condition that our solution must expand; (48) implies that initially, $u(t, \eta(t, x)) = x + \partial_x \theta(\log (1 + t), x)$, and thus if we have sufficient smallness on $\theta$ and its derivatives, the velocity of each particle stays close to the radial direction, which forces expansion.

As discussed in the introduction, in the case of $N \geq 2$, if the stars initially are far away from each other, and are then pushed further away, the gravitational interaction between two stars should be small. Thus the motion of each star should be close to that of constant velocity, as in [65], with the velocity essentially decomposing into two main parts; one driving repulsion, and one driving expansion. For each $\kappa = 1, 2, \ldots, N$, we define the error $\theta_\kappa$ and repulsive velocity $\mu_\kappa$ by the following relation

$$\eta_\kappa(t, x) = (x + \bar{x}_\kappa) + t(x + \mu_\kappa(x)) + (t + 1)\theta_\kappa(\log (1 + t), x)$$  \hspace{1cm} (49)

This form of $\eta_\kappa$ encodes the fact that the particles should have a radial velocity to force expansion, and a repulsive velocity, to force the stars away from each other.

As in [31,65], we define a new logarithmic timescale

$$\tau = \log (1 + t),$$  \hspace{1cm} (50)

and under this transformation, we can write $\eta_\kappa$ as

$$\eta_\kappa(t, x) = e^\tau \left( x + e^{-\tau} \bar{x}_\kappa + (1 - e^{-\tau})\mu_\kappa(x) + \theta_\kappa(\tau, x) \right) = e^\tau \zeta_\kappa(\tau, x),$$  \hspace{1cm} (51)

where $\zeta_\kappa$ is defined for notational convenience. Under this ansatz, we will prove that solutions to (44)–(46) with small enough $\theta_\kappa$, as well as some more technical assumptions on $\mu_\kappa$, are global-in-time.

Remark 7. Note that the logarithmic timescale in (50) is used to study certain types of self similar solutions to evolution equations (see [18]), but in our case is for convenience.
We have some definitions to record. Throughout the paper, the identity matrix \( \mathbb{R}^3 \to \mathbb{R}^3 \) will be denoted by \( I \).

Let

\[
\mathcal{M}[\kappa] = \nabla \zeta_k, \tag{52}
\]

\[
\mathcal{A}[\kappa] = (\mathcal{M}[\kappa])^{-1}, \tag{53}
\]

\[
\mathcal{J}_k = \det \mathcal{M}[\kappa], \tag{54}
\]

\[
\frac{3}{\alpha} = \beta. \tag{55}
\]

Similarly to (39), we have for \( \mathcal{A}[\kappa] \) and \( \mathcal{J}_k \),

\[
\partial \mathcal{A}[\kappa]_i^k = -\mathcal{A}[\kappa]_j^k \partial \partial_s \zeta_j^i \mathcal{A}[\kappa]_i^s, \tag{56}
\]

\[
\partial \mathcal{J}_k = \mathcal{J}_k \mathcal{A}[\kappa]_i^k \partial \partial_s \zeta_j^i, \tag{57}
\]

for \( \partial \in \{ \partial \tau, \partial_1, \partial_2, \partial_3 \} \).

Using (50)–(51) to rewrite (44), we obtain

\[
e^{-\tau} \tilde{w}_k^{\alpha} \left( \partial \tau \theta_k^i + \partial \theta_k^i \right) + e^{-\left(1 + \frac{3}{\alpha}\right)\tau} \partial_k \left( \tilde{w}_k^{1+\alpha} \mathcal{A}[\kappa]_i^k \mathcal{J}_k^{-1/\alpha} \right) + e^{-\tau} \tilde{w}_k^{\alpha} \mathcal{A}[\kappa]_i^k \partial_k \psi_k = 0, \tag{58}
\]

and upon multiplying everything on the left hand side by \( e^{\left(1 + \frac{3}{\alpha}\right)\tau} \), the system (44)–(46) becomes

\[
e^{\beta \tau} \tilde{w}_k^{\alpha} \left( \partial \tau \theta_k^i + \partial \theta_k^i \right) + \partial_k \left( \tilde{w}_k^{1+\alpha} \mathcal{A}[\kappa]_i^k \mathcal{J}_k^{-1/\alpha} \right) + e^{\beta \tau} \tilde{w}_k^{\alpha} \mathcal{A}[\kappa]_i^k \partial_k \psi_k = 0 \quad \text{in} \ I \times \Omega, \tag{59}
\]

\[
(\partial \tau \theta_k(\tau, x), \theta_k(\tau, x)) = (\hat{u}_k (\hat{\eta}_k (x)) - (\hat{\eta}_k (x) + \mu_k (x), 0) \quad \text{in} \ [\tau = 0] \times \Omega, \tag{60}
\]

\[
\tilde{w}_k = 0 \quad \text{on} \ \partial \Omega, \tag{61}
\]

**Remark 8.** The imbalance in exponential powers between the velocity term and the pressure term in (58) leads to a positive exponential in front of the velocity term in (59). This is exactly the nonlinear scaling mechanism, exhibited in [65], that will stabilise our solution and help us to prove that it is global-in-time.

For the gravitation potential term, note that in Eulerian coordinates, we have the Poisson equation (22) given by \( \Delta \phi = 4\pi \rho \), where \( \rho \) is the cumulative density \( \sum \rho_k \). Due to the compact support of each \( \rho_k \), we can use the convolution formula for Poisson’s equation and write \( \phi \) explicitly as

\[
\phi(t, x) = -\sum_{k=1}^{N} \int_{\Omega(t)} \frac{\rho_k(t, z)}{|x - z|} \, dx, \tag{62}
\]
If we then apply the flow map \( \eta_k \), for a fixed \( \kappa \), to both sides of (62), we have, for \( i = 1, 2, 3 \),

\[
\mathcal{A}[\kappa]_i^k \partial_k \psi_k = -\mathcal{A}[\kappa]_i^k \partial_k \left( \int_\Omega \frac{\tilde{w}^\alpha_k(z)}{|\eta_k(t, x) - \eta_k(t, z)|} \, dz \right)
- \sum_{\kappa' \neq \kappa} \mathcal{A}[\kappa]_i^k \partial_k \left( \int_\Omega \frac{\tilde{w}^\alpha_k(z)}{|\eta_k(t, x) - \eta_{k'}(t, z)|} \, dz \right)
- e^{-\tau} \sum_{\kappa' \neq \kappa} \mathcal{A}[\kappa]_i^k \partial_k \left( \int_\Omega \frac{\tilde{w}^\alpha_k(z)}{|\zeta_k(t, x) - \zeta_{k'}(t, z)|} \, dz \right)
- e^{-\tau} \sum_{\kappa' \neq \kappa} \mathcal{A}[\kappa]_i^k \partial_k \left( \int_\Omega \frac{\tilde{w}^\alpha_k(z)}{|\zeta_k(t, x) - \zeta_{k'}(t, z)|} \, dz \right)
= -\mathcal{G}^i_k - \sum_{\kappa' \neq \kappa} \mathcal{J}^i_{[\kappa, \kappa']}.
\tag{63}
\]

We can further rewrite \( \mathcal{G}_k \) and \( \mathcal{J}_{[\kappa, \kappa']} \). For \( \mathcal{G}_k \), note that

\[
\mathcal{G}^i_k = e^{-\tau} \mathcal{A}[\kappa](\tau, x)_i^k \partial_{x_k} \left( \int_\Omega \frac{\tilde{w}^\alpha_k(z)}{|\zeta_k(\tau, x) - \zeta_k(\tau, z)|} \, dz \right)
= -e^{-\tau} \int_\Omega \mathcal{A}[\kappa](\tau, z)_i^k \partial_{z_k} \left( \frac{1}{|\zeta_k(\tau, x) - \zeta_k(\tau, z)|} \right) \tilde{w}^\alpha_k(z) \, dz
= e^{-\tau} \int_\Omega \frac{\partial_k (\mathcal{A}[\kappa]_i^k \tilde{w}^\alpha_k)}{|\zeta_k(\tau, x) - \zeta_k(\tau, z)|} \, dz,
\tag{64}
\]

where the last step uses integration by parts, noting that \( \tilde{w}_k \) is 0 on \( \partial \Omega \). For \( \mathcal{J}_{[\kappa, \kappa']} \), we have

\[
\mathcal{J}_{[\kappa, \kappa']} = e^{-\tau} \mathcal{A}[\kappa]_i^k (\tau, x) \partial_{x_k} \left( \int_\Omega \frac{\tilde{w}^\alpha_k(z)}{|\zeta_k(\tau, x) - \zeta_{k'}(\tau, z)|} \, dz \right)
= -e^{-\tau} (\tau, x) \int_\Omega \mathcal{A}[\kappa]_i^k \partial_k \zeta_{i}^j (\tau, x) \left( \frac{\zeta_{i}^j(\tau, x) - \zeta_{k'}(\tau, z)}{|\zeta_{k'}(\tau, x) - \zeta_{k'}(\tau, z)|^3} \right) \tilde{w}_k(z) \, dz
= e^{-\tau} \int_\Omega \left( \frac{\zeta_{i}^j(\tau, x) - \zeta_{k'}(\tau, z)}{|\zeta_{k'}(\tau, x) - \zeta_{k'}(\tau, z)|^3} \right) \tilde{w}^\alpha_k \, dz,
\tag{65}
\]

where the last line is because \( \mathcal{A}[\kappa] = [\nabla \zeta_k]^{-1} \).

The \( \mathcal{G}_k \) are the \textit{self-interaction terms} and represent the part of the potential that encodes how the star is affected by its own gravity. The \( \mathcal{J}_{[\kappa, \kappa']} \) are the \textit{tidal terms} which encode how different stars affect each other via their gravitational interaction. Note that in the case of \( N = 1 \) only the self-interaction terms are present, and these terms have already been studied in our context in [32]. The tidal terms are unique to the \( N \geq 2 \) case, and understanding how to control these terms indirectly gives us information on how to configure our system initially, see Remark 11.
3.2. Initial density profiles

In this section we will fix our initial density profiles for each \( \kappa \). First we define a collection of admissible profiles.

**Definition 1.** For each \( \kappa \in \{1, 2, \ldots, N\} \), let \( \mathcal{W}_\kappa \) be the set of functions \( F : \Omega_\kappa \to \mathbb{R} \) with the following properties:

- Letting \( \text{int}(\Omega_\kappa) := \{ x \in \Omega_\kappa \mid |x - \bar{x}_\kappa| < 1 \} \), we have
  \[
  F|_{\text{int}(\Omega_\kappa)} > 0, \quad F|_{\partial \Omega_\kappa} \equiv 0. \quad (66)
  \]
- There exists a positive constant \( C > 0 \) such that for any \( x \in \Omega_\kappa \)
  \[
  \frac{1}{C} d(x, \partial \Omega_\kappa) \leq F(x) \leq C d(x, \partial \Omega_\kappa). \quad (67)
  \]
  where \( x \mapsto d(x, \partial \Omega_\kappa) \) is the distance function to \( \partial \Omega_\kappa \).
- The function given by
  \[
  x \mapsto \frac{F(x)}{d(x, \partial \Omega_\kappa)} \quad (68)
  \]
  is smooth on \( \Omega_\kappa \).

Now we fix an initial density profile for each \( \kappa = 1, 2, \ldots, N \) by choosing a function from each \( \mathcal{W}_\kappa \), which we will call \( W_\kappa \), and a constant \( \delta > 0 \) such that

\[
\delta W_\kappa(x) = w_\kappa(x) = \hat{\rho}_\kappa^{y-1}(x). \quad (69)
\]

Note that \( \delta \) is significant as we can adjust the size of our initial densities by adjusting the value of \( \delta \). Throughout, \( \delta \ll 1 \), and we will specify explicit bounds on \( \delta \) wherever necessary. This ansatz has already been used in \([32, 65]\) to find global-in-time solutions with small density. Under this definition of \( \hat{\rho}_\kappa \), the speed of sound given by \( \hat{c}_\kappa^2 = \gamma \hat{\rho}_\kappa \) will satisfy the physical vacuum condition \((17)\).

Finally, since we work from a reference domain \( \Omega \), we define for each \( \kappa \):

\[
\tilde{W}_\kappa(x) = W_\kappa(x + \bar{x}_\kappa), \quad x \in \Omega. \quad (70)
\]

Due to \((67)\), we have the relation

\[
\frac{1}{C} d(x + \bar{x}_\kappa, \partial \Omega_\kappa) \leq \tilde{W}_\kappa(x) \leq C d(x, \partial \Omega), \quad (71)
\]

as \( d(x + \bar{x}_\kappa, \partial \Omega_\kappa) = d(x, \partial \Omega) \) for all \( x \in \Omega \).

Clearly \( \delta \tilde{W}_\kappa = \tilde{w}_\kappa \), where \( \tilde{w}_\kappa \) is defined in \((47)\). We substitute for \( \tilde{W}_\kappa \), and our system becomes, for \( \kappa = 1, 2, \ldots, N \), and \( i = 1, 2, 3 \):

\[
\frac{1}{\delta} e^{\beta \tau} \tilde{W}_\kappa^\alpha \left( \partial_\tau \theta^i_\kappa + \partial_i \theta^j_\kappa \right) + \partial_k \left( \tilde{W}_\kappa^{1+\alpha} \mathcal{A}[k]_i^j \tilde{\theta}^{\alpha-1/\alpha}_\kappa \right) + \frac{1}{\delta} e^{\beta \tau} \tilde{W}_\kappa^\alpha \mathcal{A}[k]_i^j \tilde{\theta} \tilde{\psi}_\kappa = 0 \quad \text{in } I \times \Omega, \quad (72)
\]

\[
(\partial_\tau \theta_\kappa(\tau, x), \theta_\kappa(\tau, x)) = (\tilde{u}_\kappa(\hat{\eta}_\kappa(x)) - (\hat{\eta}_\kappa(x) + \mu_\kappa(x)), 0) \quad \text{in } \{ \tau = 0 \} \times \Omega, \quad (73)
\]

\[
\tilde{W}_\kappa = 0 \quad \text{on } \partial \Omega. \quad (74)
\]
Using (69) to replace $\tilde{w}_\kappa$ with $\tilde{W}_\kappa$ in (64) and (65), we obtain

$$G^i_\kappa = \delta^\kappa_\alpha e^{-\tau} \int_\Omega \frac{\partial_k (\mathcal{A}_k^\kappa \tilde{W}_\alpha)}{|\zeta^\kappa_\kappa (\tau, x) - \zeta^\kappa_\kappa (\tau, z)|} \, dz,$$  \hspace{1cm} (75)

$$G^i_{[\kappa, \kappa']} = \delta^\kappa_\alpha e^{-\tau} \int_\Omega \frac{(\zeta^\kappa_i (\tau, x) - \zeta^\kappa_i (\tau, z)) \tilde{W}_\alpha}{|\zeta^\kappa_\kappa (\tau, x) - \zeta^\kappa_\kappa (\tau, z)|^3} \, dz.$$  \hspace{1cm} (76)

4. Notation

4.1. General notation

For a function $F : \mathcal{O} \rightarrow \mathbb{R}$, some domain $\mathcal{O}$, the support of $F$ is denoted $\text{supp } F$. For a real number $\lambda$, the ceiling function, denoted $\lceil * \rceil_\lambda$, is the smallest integer $M$ such that $\lambda \leq M$. For two real numbers $A$ and $B$, we say $A \lesssim B$ if there exists a positive constant $C$ such that

$$A \leq CB,$$  \hspace{1cm} (77)

and for two real valued functions $f$ and $g$, we say $f \lesssim g$ if $f(x) \lesssim g(x)$ holds pointwise. For two real-valued non-negative functions $f, g : \mathcal{O} \rightarrow \mathbb{R}_{\geq 0}$, some domain $\mathcal{O}$, we say $f \sim g$ if there exist positive constants $c_1$ and $c_2$ such that

$$c_1 g(x) \leq f(x) \leq c_2 g(x),$$  \hspace{1cm} (78)

for all $x \in \mathcal{O}$.

We also record the definition of the radial function on $\Omega = B_1$ the unit ball:

$$r : B_1 \rightarrow \mathbb{R}_{\geq 0}$$

$$x \mapsto r(x) := |x|. $$  \hspace{1cm} (79)

It is convenient to define shorthand for the distance function on $\Omega$. Define

$$d_\Omega(x) = d(x, \partial \Omega).$$  \hspace{1cm} (80)

4.2. Derivatives

As we have seen above, rectangular derivatives will be denoted as $\partial_i$, for $i$ in $1, 2, 3$. In addition, we define various rectangular and $\zeta_\kappa$ Lie derivatives that will be used throughout. The gradient, divergence, and curl on vector fields are given by

$$[\nabla F]^i_j = \partial_j F^i,$$  \hspace{1cm} (81)

$$\text{div } F = \partial_i F^i,$$  \hspace{1cm} (82)

$$[\text{curl } F]^i = \varepsilon_{ijk} \partial_j F^k,$$  \hspace{1cm} (83)

for $i, j = 1, 2, 3$. 

The $\zeta_\kappa$ versions are given by

$$[\nabla_{\zeta_\kappa} F]^i_j = \mathcal{A}[\kappa]^k_j \partial_k F^i, \quad (84)$$

$$\text{div}_{\zeta_\kappa} F = \mathcal{A}[\kappa]^i_j \partial_j F^i, \quad (85)$$

$$[\text{curl}_{\zeta_\kappa} F]^i_j = \varepsilon_{ijk} \mathcal{A}[\kappa]^s_j \partial_k F^s. \quad (86)$$

In addition, we also need the matrix $\zeta_\kappa$ curl, given by

$$[\text{Curl}_{\zeta_\kappa} F]^i_j = \mathcal{A}[\kappa]^j_i \partial_i F^j - \mathcal{A}[\kappa]^i_j \partial_j F^i. \quad (87)$$

Recall (29); our reference domain is the closed unit ball in $\mathbb{R}^3$, $\Omega = B_1$. There exists a natural choice of spherical coordinates $(r, \omega, \phi)$. An advantage of this choice of domain is that we can privilege the outward normal derivative, the direction in which the degeneracy of the problem occurs, due to the vacuum boundary condition (17).

Accordingly we will, in essence, use $\partial_r$ as the normal derivative, and $\partial_\omega, \partial_\phi$ as the tangential derivatives. However we modify these derivatives by using linear combinations. These modifications allow for better commutation relations with the rectangular derivatives. Let the angular derivatives $\hat{\partial}_{ij}$ and radial derivative $\Lambda$ be given by

$$\hat{\partial}_{ij} := x_i \partial_j - x_j \partial_i, \quad (88)$$

$$\Lambda := x_i \partial_i = r \partial_r, \quad (89)$$

where the $x_i$ and $\partial_j$ are rectangular, and $i, j$ run through 1, 2, 3. On regions separated from the origin, we will use the following decomposition frequently:

$$\partial_i = \frac{x_j}{r^2} \hat{\partial}_{ji} + \frac{x_i}{r^2} \Lambda. \quad (90)$$

**Remark 9.** The coefficients of the derivatives we have defined go to 0 at the origin, which means we can only use them for estimates on a region separated from the origin. This can be dealt with using a partition of unity argument. Near the boundary we use these modified spherical derivatives, and on the interior, we are free to use rectangular derivatives as the degeneracy at the vacuum boundary is not an issue in this case.

Now, for $m \in \mathbb{Z}_{\geq 0}$, and $\underline{n} = (n_1, n_2, n_3) \in \mathbb{Z}^3_{\geq 0}$, we define

$$\mathcal{A}^m \hat{\partial}^{\underline{n}} := \mathcal{A}^m \hat{\partial}_{12}^{n_1} \hat{\partial}_{13}^{n_2} \hat{\partial}_{23}^{n_3}. \quad (91)$$

Although there are six non-zero $\hat{\partial}$ derivatives to consider, $\hat{\partial}_{ij} = -\hat{\partial}_{ji}$, so (91) covers all cases. For such an $\underline{n} \in \mathbb{Z}^3_{\geq 0}, |\underline{n}| = n_1 + n_2 + n_3$. Similarly for rectangular derivatives we define, for $\underline{k} = (k_1, k_2, k_3) \in \mathbb{Z}^3_{\geq 0}$,

$$\nabla^{\underline{k}} = \partial_1^{k_1} \partial_2^{k_2} \partial_3^{k_3}. \quad (92)$$
We have the commutation relations between the modified spherical and rectangular derivatives, for \( i, j, k, m \in \{1, 2, 3\} \), given by

\[
\begin{align*}
\mathcal{L}^{ij} \Lambda &= 0, \quad (93) \\
\mathcal{L}^{ij} \mathcal{L}^{jk} &= \mathcal{L}^{ik}, \quad (94) \\
[\partial_m, \Lambda] &= \partial_m, \quad (95) \\
[\partial_m, \mathcal{L}^{ji}] &= \delta_{mj} \partial_i - \delta_{mi} \partial_j. \quad (96)
\end{align*}
\]

We also define commutators between the higher order differential operator defined in (91), and \( \nabla \):

\[
\begin{align*}
\left( \nabla, \Lambda^m \mathcal{L}^n \right) F^i_j &= \partial_j \left( \Lambda^m \mathcal{L}^n \left( \partial_i F^i \right) \right). \quad (97)
\end{align*}
\]

We can do the same thing with \( \nabla_{\zeta \kappa} \):

\[
\begin{align*}
\left( \nabla_{\zeta \kappa}, \Lambda^m \mathcal{L}^n \right) F^i_j &= \mathcal{A}[\kappa]^k_j \partial_k \left( \Lambda^m \mathcal{L}^n \left( \partial_i F^i \right) \right) - \Lambda^m \mathcal{L}^n \left( \mathcal{A}[\kappa]^k_j \partial_k F^i \right), \quad (98) \\
\left( \nabla_{\zeta \kappa}, \nabla^k \right) F^i_j &= \mathcal{A}[\kappa]^k_j \partial_k \left( \nabla^k F^i \right) - \nabla^k \left( \mathcal{A}[\kappa]^k_j \partial_k F^i \right). \quad (99)
\end{align*}
\]

There is no corresponding definition to (99) for \( \nabla \), as \( \nabla \) and \( \nabla^k \) commute for all \( k \in \mathbb{Z}_{\geq 0} \). Note that (98) and (99) also define analogous objects for \( \text{Curl}_{\zeta \kappa} \) and \( \text{div}_{\zeta \kappa} \) as the former is \( \nabla_{\zeta \kappa} - \nabla^T_{\zeta \kappa} \), and the latter is \( \text{Tr} \nabla_{\zeta \kappa} \).

### 5. Energy Function

Following the strategy set out in Remark 9, define a smooth radial cutoff function \( \chi \) on the closed unit ball such that

\[
\chi = \begin{cases} 
1 & \text{if } r \in [3/4, 1] \\
0 & \text{if } r \in [0, 1/4]
\end{cases}. \quad (100)
\]

In addition, define \( \tilde{\chi} \) by

\[
\tilde{\chi} = 1 - \chi. \quad (101)
\]

Recalling the definition of \( \alpha \) given in (27), we now define our energy spaces.

**Definition 2.** (Energy Spaces) Let \( b \in \mathbb{Z}_{\geq 0} \) and define the space \( \mathcal{X}^b_{\kappa}, \kappa = 1, 2, \ldots, N, \) by

\[
\mathcal{X}^b_{\kappa} = \left\{ \mathcal{W}^b_{\kappa} F \in L^2(\Omega) : \sum_{m + |\mathbf{k}| = 0}^b \int_{\Omega} \mathcal{W}^{a+m}_{\kappa} \left( \chi |\Lambda^m \mathcal{L}^n F|^2 + \tilde{\chi} |\nabla^k F|^2 \right) dx < \infty \right\}.
\]

The norm of \( \mathcal{X}^b_{\kappa} \) is given by

\[
\|F\|_{\mathcal{X}^b_{\kappa}}^2 = \sum_{m + |\mathbf{k}| = 0}^b \int_{\Omega} \chi \mathcal{W}^{a+m}_{\kappa} |\Lambda^m \mathcal{L}^n F|^2 dx + \sum_{|\mathbf{k}| = 0}^b \int_{\Omega} \tilde{\chi} \mathcal{W}^a_{\kappa} |\nabla^k F|^2 dx. \quad (102)
\]
For $\mathcal{D} \in \{\nabla, \nabla_{\kappa} \times, \text{div}, \text{div}_{\kappa}, \text{Curl}, \text{Curl}_{\kappa}\}$ define the space $\mathcal{Y}_b^\kappa(\mathcal{D})$ by

$$\mathcal{Y}_b^\kappa(\mathcal{D}) = \left\{ \tilde{W}_{\kappa}^{1+\alpha} \mathcal{D} F \in L^2(\Omega) : \right. $$

$$\left. \sum_{m+|\alpha|+|\vec{\lambda}|=0}^b \int_{\Omega} \tilde{W}_{\kappa}^{1+\alpha+m} \mathcal{J}_\kappa^{-\frac{1}{\alpha}} \left( \chi \left| \mathcal{D} A^m \mathcal{D}^2 F \right|^2 + \tilde{\chi} \left| \mathcal{D} \nabla^k F \right|^2 \right) \, dx < \infty \right\},$$

with semi norm given by

$$\|F\|_{\mathcal{Y}_b^\kappa(\mathcal{D})}^2 = \sum_{m+|\alpha|+|\vec{\lambda}|=0}^b \int_{\Omega} \tilde{W}_{\kappa}^{1+\alpha+m} \mathcal{J}_\kappa^{-\frac{1}{\alpha}} \left( \chi \left| \mathcal{D} A^m \mathcal{D}^2 F \right|^2 + \tilde{\chi} \left| \mathcal{D} \nabla^k F \right|^2 \right) \, dx.$$

(103)

**Remark 10.** The powers of $\tilde{W}_{\kappa}$ in the integrals involving $\tilde{\chi}$ in (102)–(103) are not consistent with what we see in the definition of the energy spaces. However, on $\text{supp } \tilde{\chi}$, $\tilde{W}_{\kappa} \sim 1$ so this discrepancy does not create issues.

We now define our higher order energy function and Curl$_{\kappa}$ energy function.

**Definition 3.** (Higher Order Energy and Curl Functions) Let $b \in \mathbb{Z}_{\geq 0}$. Then the individual energy functions of order $b$ for $(\partial_\tau \theta_\kappa, \theta_\kappa)$, $\kappa = 1, 2, \ldots, N$, is given by

$$S_b^\kappa(\tau) = S_b^\kappa(\partial_\tau \theta_\kappa, \theta_\kappa, \tau) = \sup_{0 \leq \tau' \leq \tau} \left( \frac{1}{\delta} e^{\beta \tau'} \|\partial_\tau \theta_\kappa(\tau')\|_{\mathcal{X}_{\kappa}^b}^2 + \|\theta_\kappa(\tau')\|_{\mathcal{Y}_{\kappa}^b}^2 + \|\theta_\kappa(\tau')\|_{X_{\kappa}^b(\text{div}_{\kappa})}^2 + \frac{1}{\alpha} \|\theta_\kappa(\tau')\|_{Y_{\kappa}^b(\text{curl}_{\kappa})}^2 \right).$$

(104)

The Curl$_{\kappa}$ energy function of order $b$ for $(\partial_\tau, \theta_\kappa, \theta_\kappa)$ is given by

$$C_b^\kappa(\tau) = C_b^\kappa(\partial_\tau \theta_\kappa, \theta_\kappa, \tau) = \sup_{0 \leq \tau' \leq \tau} \left( \|\partial_\tau \theta_\kappa(\tau')\|_{\mathcal{X}_{\kappa}^b(\text{curl}_{\kappa})}^2 + \|\theta_\kappa(\tau')\|_{Y_{\kappa}^b(\text{curl}_{\kappa})}^2 \right).$$

(105)

Then the cumulative energy function and Curl$_{\kappa}$ energy function of order $b$ are

$$S_b(\tau) = \sum_{\kappa=1}^N S_b^\kappa(\tau),$$

(106)

$$C_b(\tau) = \sum_{\kappa=1}^N C_b^\kappa(\tau).$$

(107)
6. Main Result and A Priori Assumptions

6.1. Main result

In this section we will state the central theorem of this paper, global-in-time existence of the system (72)–(74). First we state the local-in-time theory for this system. Details on its construction are given in Appendix A.

Recall the definition of $\delta$, the smallness parameter for the initial density profiles defined in (69), and the repulsive velocities of each star $\mu_\kappa$, defined in (49).

**Theorem 2.** (Local Well-Posedness of the Free Boundary $N$-Body Euler–Poisson System) Assume $\gamma = 1 + \frac{1}{n}$ for some $n \in \mathbb{Z}_{\geq 2}$, or $\gamma \in (1, 14/13)$. Let $M$ be an integer such that $M \geq 2\lceil \alpha \rceil + 12$. Additionally, assume that $\nabla \tilde{W}_\kappa$, $\nabla \mu_\kappa \in \mathcal{X}_\kappa^M$ for $\kappa = 1, 2, \ldots, N$. Let $\tilde{\mu}_\kappa : \Omega_\kappa \to \mathbb{R}^3$ and $(\tilde{\eta}_\kappa(x) = x + \tilde{x}_\kappa) : \Omega \to \Omega_\kappa$ be such that the separation condition

$$\min_{\kappa, \kappa' = 1, 2, \ldots, N} \min_{\kappa \neq \kappa'} \text{dist}(\Omega_\kappa, \Omega_{\kappa'}) = \text{dist}(\Omega + \tilde{x}_\kappa, \Omega + \tilde{x}_{\kappa'}) > 0$$

holds, and the bound

$$S_M(0) + C_M(0) = \sum_{\kappa = 1}^{N} \left[ S^M_\kappa(\tilde{\mu}_\kappa(\tilde{\eta}_\kappa(x)) - (\tilde{\eta}_\kappa(x) + \mu_\kappa(x)), 0, 0) + C^M_\kappa(\tilde{\mu}_\kappa(\tilde{\eta}_\kappa(x)) - (\tilde{\eta}_\kappa(x) + \mu_\kappa(x)), 0, 0) \right] < \infty$$

holds. Then there exists a $T > 0$ such that we can find a unique solution $\{(\partial_\tau \theta_\kappa, \theta_\kappa)|\kappa = 1, 2, \ldots, N\}$ to (72)–(74) on the interval $[0, T]$ with

$$S_M(\tau) + C_M(\tau) \leq 2(S_M(0) + C_M(0) + \sqrt{\delta}), \quad \forall \tau \in [0, T],$$

$$(\partial_\tau \theta_\kappa(0), \theta_\kappa(0)) = (\tilde{\mu}_\kappa(\tilde{\eta}_\kappa(x)) - (\tilde{\eta}_\kappa(x) + \mu_\kappa(x)), 0) \quad \forall \kappa = 1, 2, \ldots, N. \quad (111)$$

Moreover, the function $\tau \mapsto S_M(\tau)$ is continuous.

Before we formulate our main result, we introduce the Strong Separation Condition (SSC), that will be key in formulating our main result. To motivate this condition, we can first calculate a quantitative lower bound on the distance between the fluid bodies at time $t$. For distinct $\kappa, \kappa' \in \{1, \ldots, N\}$, we have

$$d(\Omega_\kappa(t), \Omega_{\kappa'}(t)) = \inf_{y \in \Omega_\kappa(t), y' \in \Omega_{\kappa'}(t)} |y - y'| = \inf_{x, z \in \Omega} |\eta_\kappa(t, x) - \eta_{\kappa'}(t, z)|$$

$$= (t + 1) \inf_{x, z \in \Omega} |\xi_\kappa(t, x) - \xi_{\kappa'}(t, z)|$$

$$= (t + 1) \inf_{x, z \in \Omega} \left| (1 - e^{-T})(\mu_\kappa(x) - \mu_{\kappa'}(z)) + e^{-T}(\tilde{x}_\kappa - \tilde{x}_{\kappa'}) + (x - z) + (\theta_\kappa - \theta_{\kappa'}) \right|$$

$$\geq (t + 1) \inf_{x, z \in \Omega} \left| (1 - e^{-T})(x + \mu_\kappa(x) - (z + \mu_{\kappa'}(z))) + e^{-T}((x + \tilde{x}_\kappa - (z + \tilde{x}_{\kappa'})) - |(\theta_\kappa - \theta_{\kappa'})| \right|. \quad (112)$$

With this calculation in mind, we introduce the Strong Separation Condition.
**Definition 4.** (*Strongly Separated Initial Configurations of the Free Boundary N-Body Euler–Poisson System*) We say that an initial configuration for the stars in the Free Boundary N-Body Euler–Poisson System satisfies the Strong Separation Condition for \( L > 0 \) if

\[
\min_{\kappa, \kappa' = 1, 2, \ldots, N} \inf_{\lambda \in [0, 1]} \inf_{x, z \in \Omega} |(1 - \lambda)((x + \mu_{\kappa}(x)) - (z + \mu_{\kappa'}(z))) + \lambda((x + \bar{x}_{\kappa}) - (z + \bar{x}_{\kappa'}))| \geq L
\]  

holds.

**Theorem 3.** (Global Existence for the Free Boundary N-Body Euler–Poisson System) Assume \( \gamma = 1 + \frac{1}{n} \) for some \( n \in \mathbb{Z}_{\geq 2} \), or \( \gamma \in (1, 14/13) \). Let \( \{ (\partial \tau \theta_{\kappa}, \theta_{\kappa}) | \kappa = 1, 2, \ldots, N \} \) be the solution to (72)–(74) on \([0, T]\), in the sense of Theorem 2, for some \( M \geq 2[\ast] \alpha + 12 \). Additionally, assume that \( \nabla \tilde{W}_{\kappa} \in \mathcal{X}_{\kappa}^M \) for \( \kappa = 1, 2, \ldots, N \). Then there exists \( L > 0 \) sufficiently large, and \( \delta, \varepsilon_0 > 0 \) sufficiently small such that if the Strong Separation Condition from Definition 4 holds for \( L \), then for all \( 0 \leq \varepsilon \leq \varepsilon_0 \) with

\[
S_M(0) + C_M(0) + \| \nabla \mu_{\kappa} \|_{\mathcal{X}_{\kappa}^M}^2 \leq \varepsilon,
\]  

there exists a global-in-time solution to (72)–(74), with the initial conditions as in (73), and there exists a constant \( C \) such that

\[
S_M(\tau) \leq C \left( \varepsilon + \sqrt{\delta} \right), \quad \forall \tau \in [0, \infty).
\]  

Additionally, there are \( \tau \)-independent functions \( \theta_{\kappa}^{(\infty)} : \Omega \to \mathbb{R}^3 \) such that

\[
\left\| \theta_{\kappa}(\tau) - \theta_{\kappa}^{(\infty)} \right\|_{\mathcal{X}_{\kappa}^M} \to 0, \quad \tau \to \infty.
\]  

**Remark 11.** We see that the Strong Separation Condition, along with the global energy bound (115), guarantees that the fluid domains stay separated for all time. Moreover, we remark that this condition will also also arise naturally when trying to find sufficient bounds on the tidal terms \( \mathcal{I}_{[\kappa, \kappa']} \), defined in (63), to prove global-in-time existence of our solutions. Hence studying the tidal terms gives us crucial information on the initial geometry of our star configurations. It is clear that this condition is a lower bound on any convex combination of the relative positions and velocities.

### 6.2. A priori assumptions

In this section we list all the assumptions we will make to prove Theorem 3. First we make explicit the assumption, implicit in (114), that \( \nabla \mu_{\kappa} \) must be small in the \( \mathcal{X}_{\kappa}^M \) norm for \( \kappa = 1, 2, \ldots, N \). Let \( 0 < \varepsilon_1 \ll 1 \). We assume

\[
\| \nabla \mu_{\kappa} \|_{\mathcal{X}_{\kappa}^M} \leq \sqrt{\varepsilon_1}, \quad \kappa = 1, 2, \ldots, N.
\]
Let $0 < \varepsilon_2 \ll 1$. We specify the $L$ for which the Strong Separation Condition (113) holds. Assume

$$\min_{\kappa, \kappa' = 1, 2, \ldots, N} \inf_{\lambda \in [0, 1]} \inf_{x, z \in \Omega} |(1 - \lambda)((x + \mu_{\kappa}(x)) - (z + \mu_{\kappa'}(z))) + \lambda((x + \bar{\mu}_{\kappa}) - (z + \bar{\mu}_{\kappa'}))| \geq 1 + \varepsilon_2.$$  \hspace{1cm} (118)

Now we state our a priori assumptions on the solution to (72)–(74). There exists a $T > 0$, depending on $\varepsilon_2$, such that on the time interval $[0, T]$, the solution to (72)–(74) satisfies

$$S_M(\tau) \leq \varepsilon_2, \quad \forall \tau \in [0, T],$$  \hspace{1cm} (119)

$$\|\mathcal{J}[\kappa] - I\|_{L^\infty(\Omega)} \leq \varepsilon_2, \quad \kappa = 1, 2, \ldots, N, \quad \forall \tau \in [0, T],$$  \hspace{1cm} (120)

$$\|\mathcal{J} - 1\|_{L^\infty(\Omega)} \leq \varepsilon_2, \quad \kappa = 1, 2, \ldots, N \forall \tau \in [0, T],$$  \hspace{1cm} (121)

$$\sum_{\kappa = 1}^{N} \|\theta_{\kappa}\|_{L^\infty(\Omega)} \leq \varepsilon_2, \quad \forall \tau \in [0, T].$$  \hspace{1cm} (122)

As a justification for why we can make our a priori assumptions, note that such a time interval $[0, T]$ where (118)–(122) hold must exist for small enough initial data by the local well-posedness theory set out in Theorem 2. Once we have used these assumptions to prove Theorem 3, we shall use the global-in-time energy bound (115) to improve our a priori assumptions, thereby justifying them via a continuity argument.

Just like $\delta$ defined in (69), both $\varepsilon_1$ and $\varepsilon_2$ will be need to be small for our proofs. Throughout they will be $\ll 1$, and where needed we will state any explicit bounds for them.

**Remark 12.** (Asymptotic Lagrangian Quantities) Note that assumption (114) means that each repulsive velocity $\mu_{\kappa}$ is very close to a constant vector $\bar{\mu}_{\kappa}$. Thus we can write our initial velocities as

$$\hat{u}_{\kappa}(x) = x - \bar{x}_{\kappa} + \bar{\mu}_{\kappa} + o(1), \quad \text{as} \quad \varepsilon, \delta \to 0, \quad x \in \Omega_{\kappa}.$$  \hspace{1cm} (123)

As discussed in Section 3.1, $x - \bar{x}_{\kappa}$ corresponds to expansion, and $\bar{\mu}_{\kappa}$ corresponds to repulsion. Moreover, the Lagrangian flow maps, and the Lagrangian velocities take the form

$$\eta_{\kappa}(t, x) = x + \bar{x}_{\kappa} + t(\bar{\mu}_{\kappa} + o(1)), \quad \text{as} \quad \varepsilon, \delta \to 0, \quad x \in \Omega,$$  \hspace{1cm} (124)

$$v_{\kappa}(t, x) = u_{\kappa}(t, \eta_{\kappa}(t, x)) = \partial_t \eta_{\kappa}(t, x) = x + \bar{\mu}_{\kappa} + o(1), \quad \text{as} \quad \varepsilon, \delta \to 0, \quad x \in \Omega.$$  \hspace{1cm} (125)

**Remark 13.** (Eulerian Variables) Recall the relation (43) given by

$$\rho_{\kappa}(t, \eta_{\kappa}(t, x)) = \mathcal{J}_{\kappa}^{-1}(t, x) = \rho_{\kappa}(x + \bar{x}_{\kappa})\mathcal{J}_{\kappa}^{-1}(t, x),$$  \hspace{1cm} (126)
Global Existence for the N Body Euler–Poisson System

for $x \in \Omega$. Using the definition of $\eta_\kappa$ from (49), we obtain

$$\rho_\kappa(t, y) = (t + 1)^{-3} \frac{1}{3} \rho_\kappa \left( \eta_\kappa^{-1}(t, y) + \bar{x}_\kappa \right) \mathcal{J}^{-1}(\log(t + 1), \eta_\kappa^{-1}(t, y)) \to 0, \ t \to \infty,$$

(127)
as $\dot{\rho}_\kappa$ is bounded and $\mathcal{J} \sim 1$ due to the a priori assumption (121) as well as the global energy bound (115). From the definition of $\eta_\kappa$ (51) as well as $\mathcal{J} = (t + 1)^{3} \mathcal{J} \sim (t + 1)^{3}$, we see that the fluid domain for each $\kappa$, $\Omega_\kappa(t)$, is expanding in time, and is close to a uniformly scaled and shifted transformation of $\Omega_\kappa(0)$ for each fixed $t$, due to the fact that $\theta_\kappa$ is uniformly small in time, and $\mu_\kappa$ is uniformly in space close to a constant vector.

Finally, we can also calculate the Eulerian velocity, and we obtain

$$u(t, y) = \frac{y - \bar{x}_\kappa}{t + 1} + \partial_\tau \theta_\kappa(\log(t + 1), \eta_\kappa^{-1}(t, y)) + \frac{\mu_\kappa(\eta_\kappa^{-1}(t, y))}{t + 1},$$

(128)
where the second equality is due to the fact that $\tau = \log(t + 1)$. Now, the global energy bound (115) implies that $\partial_\tau \theta_\kappa \to 0$, and $\mu_\kappa$ is bounded by the mean value theorem and (117). So we have that

$$u(t, y) \to 0, \ t \to \infty.$$  

(129)

Remark 14. (Examples of constant repulsive velocities) We find a large class of initial configurations that satisfy the Strong Separation Condition (118) if we set $\mu_\kappa(x) \equiv \bar{\mu}_\kappa = \bar{x}_\kappa$ for each $\kappa = 1, 2, \ldots, N$. Then (118) is satisfied by the set $\{\bar{x}_1, \ldots, \bar{x}_N\}$, such that

$$\min_{\kappa \neq \kappa'} \left| \bar{x}_\kappa - \bar{x}_{\kappa'} \right| \geq 3 + \varepsilon_2.$$  

(130)

Thus, any initial configuration of stars, with repulsive velocity equal to the initial displacement of their centre from the origin, launches a global-in-time solution as long as they are sufficiently separated so that (130) holds. Figure 1 represents a particularly symmetric example.

Remark 15. As a final remark in this section, we go back to the fact that the Strong Separation Condition follows quite naturally in (112) when making sure the supports of the stars remain positively separated for all time. We can repeat this procedure under generalisations for the shapes of the stars. The simplest generalisation of our setup is when the stars are balls centred on $\bar{x}_\kappa$, with radii $r_\kappa$. In this case, our flow maps $\eta_\kappa$ would be defined as

$$\eta_\kappa : I \times \Omega \to \Omega_\kappa(t)$$

$$ (t, x) \mapsto \eta_\kappa(t, x) := r_\kappa x + \bar{x}_\kappa + t(x + \mu_\kappa) + (t + 1)\theta_\kappa.$$  

(131)

Then, going through the same identities and estimates as in (112), for distinct $\kappa, \kappa' \in \{1, \ldots, N\}$, we have

$$d(\Omega_\kappa(t), \Omega_{\kappa'}(t))$$
\[ \geq (t + 1) \inf_{x,z \in \Omega} \left\| (1 - e^{-\tau})((x + \mu_k(x)) - (z + \mu_{k'}(z))) \\ + e^{-\tau}((r_k x + \bar{x}_k) - (r_{k'} z + \bar{x}_{k'})) \right\|, \]  

(132)

and thus, compared to (118), a generalised Strong Separation Condition would be

\[ \min_{\kappa, \kappa' = 1, 2, \ldots, N} \inf_{x,z \in \Omega} \inf_{\lambda \in [0,1]} |(1 - \lambda)((x + \mu_k(x)) - (z + \mu_{k'}(z))) \\ + \lambda((r_k x + \bar{x}_k) - (r_{k'} z + \bar{x}_{k'}))| \geq 1 + \varepsilon_2, \]  

(133)

as one would expect due to the fact that it is a lower bound on any convex combination of the relative positions and velocities.

7. Estimates for the Gravitational Potential

In this section we obtain the estimates we need for the self interaction and tidal terms defined in (63), \( \mathcal{G}_k \) and \( \mathcal{J}_{[k,k']} \), to prove global-in-time existence of our solution. The estimates for \( \mathcal{G}_k \) will be closely follow the methods used in [32], as they have to deal with the corresponding term in the One Body Euler–Poisson system.

However, the tidal terms \( \mathcal{J}_{[k,k']} \) will clearly only appear in the case of two or more interacting bodies, and in the estimates for these terms we make crucial use of the Strong Separation Condition (118).

7.1. Tidal term estimates

**Proposition 1.** Assume \( \gamma = 1 + \frac{1}{n} \) for some \( n \in \mathbb{N} \), or \( \gamma \in (1, 14/13) \). Let \( \{ (\partial_\tau \theta_k, \theta_k) \}_{k = 1, 2, \ldots, N} \) be the solution to (72)–(74) on \([0, T]\), in the sense of Theorem 2, for some \( M \geq 2\lceil \alpha + 12 \rceil \). Suppose the assumptions (117)–(122) hold. Assume that \( \nabla \tilde{W}_k \in \mathcal{L}^M_k \) for \( k = 1, 2, \ldots, N \). Then for all \( \tau \in [0, T] \), we have:

\[ \sum_{k' \neq k} \left( \sum_{m + |n| = 0} \int_\Omega \chi \tilde{W}_k^{\alpha + m} \left| \Lambda^m \mathcal{J}_{[k,k']} \right|^2 dx \right) + \sum_{|k| = 0} \int_\Omega \tilde{W}_k^{\alpha} \left| \nabla^k \mathcal{J}_{[k,k']} \right|^2 dx \right) \lesssim \delta^{2\alpha} e^{-2\tau}. \]  

(134)

**Proof.** We begin with the integrals on the left hand side of (134) that are localised on \( \text{supp} \chi \). When \( m + |n| = 0 \), for \( i = 1, 2, 3 \), we have

\[ \mathcal{J}^i_{[k,k']} = \delta^\alpha e^{-\tau} \left( \int_\Omega \frac{\xi_k^i(x) - \xi_{k'}^i(z)}{|\xi_k(x) - \xi_{k'}(z)|^3} dz \right). \]  

(135)
Global Existence for the \( N \) Body Euler–Poisson System

Initial displacement of centres from origin, \( \bar{x}_\kappa \).

Repulsive velocities, \( \mu_\kappa(x) \equiv \bar{x}_\kappa \).

Stars at \( \tau = 0 \).

Expansion of stars for \( \tau > 0 \).

Fig. 1. Example of an initial configuration with \( \mu_\kappa(x) \equiv \bar{x}_\kappa \).
Thus, we have

\[
\left| \mathcal{J}_{\kappa, \kappa'} \right|^2 = \delta^{2\alpha} e^{-2\tau} \left( \int_{\Omega} \left( \frac{\zeta^i \tau}{|\xi^i \tau(z)|^3} \right) \bar{W}_{\kappa}^a \, dz \right)^2 \\
\leq \delta^{2\alpha} e^{-2\tau} \left( \int_{\Omega} \left| \frac{\bar{W}_{\kappa}^a}{|\xi^i \tau(z)|^2} \right| \, dz \right)^2
\]  

(136)

Now, we have that \( \xi^i \tau, x \) = \( x + e^{-\tau} \bar{x} + (1 - e^{-\tau}) \mu^i \tau (x) + \theta^\tau \), and so

\[
\frac{1}{|\xi^i \tau(z)|^2} = \frac{1}{\left| (1 - e^{-\tau})(\mu^i \tau(z)) + e^{-\tau}(\bar{x} + x) + (\theta^\tau - \bar{x}) \right|^2} \\
\leq \frac{1}{\left| (1 - e^{-\tau})(\mu^i \tau(z)) + e^{-\tau}(\bar{x} + x) - (\theta^\tau - \bar{x}) \right|^2} \\
\leq 1,
\]

(137)

where, similarly to (112), the first bound is due to the reverse triangle inequality, and the second is due to the Strong Separation Condition (118), with \( \lambda = e^{-\tau} \), as well as the bound

\[
|\theta^\tau - \bar{x}^\tau \right| \leq \sup_{0 \leq \tau \leq T} \left( \sum_{\kappa = 1}^{N} \| \theta^\tau \|_{L^\infty(\Omega)} \right) \leq \varepsilon_2,
\]

due to the a priori assumption (122). Thus,

\[
\left| \mathcal{J}_{\kappa, \kappa'} \right|^2 \leq \delta^{2\alpha} e^{-2\tau} \left\| \bar{W}_{\kappa}^a \right\|_{L^\infty(\Omega)}^{2\alpha} \leq \delta^{2\alpha} e^{-2\tau},
\]

(138)

where to go from (136) to (138), we use (137), the fact that \( \Omega \) is a compact domain, and the fact that \( \bar{W}_{\kappa} \) is in \( L^\infty(\Omega) \).

**Remark 16.** Since these tidal terms measure the gravitational interaction between the stars, it is natural that the separation of the bodies would influence our estimates, and indeed we see in the estimates above that the Strong Separation Condition, (118), is used. This will persist at higher orders as we shall see with the remaining tidal term estimates.

When \( m + |n| \geq 1 \), we instead write

\[
A^m \mathcal{J}_{\kappa, \kappa'}^i = \delta^a e^{-\tau} A^m \mathcal{J}_{\kappa, \kappa'}^i \left( \int_{\Omega} \frac{\zeta^i \tau^a}{|\xi^i \tau(z)|^3} \, dz \right) \\
= \frac{\delta^a e^{-\tau} A^m \mathcal{J}_{\kappa, \kappa'}^i \int_{\Omega} \frac{\bar{W}_{\kappa}^a}{|\xi^i \tau(z)|^3} \, dz}{\bar{m}_1} + \frac{\delta^a e^{-\tau} A^m \mathcal{J}_{\kappa, \kappa'}^i \int_{\Omega} \frac{1}{|\xi^i \tau(z)|^1} \, dz}{\bar{m}_2}
\]
due to applying the Leibniz rule to $A^m \partial^m \mathcal{L}_{[\kappa, \kappa']}$, and the last term on the right hand side, $\mathcal{I}_3$, is every resulting term except for the cases when all the derivatives fall on either $(\zeta^i_\kappa(x) - \zeta^i_{\kappa'}(z))$, which is $\mathcal{I}_1$, or $|\zeta_\kappa(x) - \zeta_{\kappa'}(z)|^{-3}$, which is $\mathcal{I}_2$. The $\mathcal{L}(a, b, c, d)$ are constant coefficients resulting from the application of the Leibniz rule.

We will show the estimates for $\mathcal{I}_1$ and $\mathcal{I}_2$, with $\mathcal{I}_3$ following similarly. We begin with $\mathcal{I}_1$ which is the simplest term, and then move on to $\mathcal{I}_2$ which requires more care, especially when applying the Leibniz rule to $A^m \partial^m \left( |\zeta_\kappa(x) - \zeta_{\kappa'}(z)|^{-3} \right)$.

**Bound for $\mathcal{I}_1$.**

Using (137) and the fact that $\tilde{W}_\kappa$ is in $L^\infty(\Omega)$ for all $\kappa$, we have

$$\int_\Omega \chi \tilde{W}_\kappa^{a+m} |\mathcal{I}_1|^2 \, dx \lesssim \delta^{2a} e^{-2\tau} \int_\Omega \chi \tilde{W}_\kappa^{a+m} \left| A^m \partial^m \zeta_\kappa(x) \int_\Omega A^m \partial^m \zeta_{\kappa'}(z) \frac{\tilde{W}_\kappa^{a} dz}{|\zeta_\kappa(x) - \zeta_{\kappa'}(z)|^3} \right|^2 \, dx$$

$$\lesssim \delta^{2a} e^{-2\tau} \int_\Omega \chi \tilde{W}_\kappa^{a+m} \left| A^m \partial^m \zeta_\kappa \right|^2 \, dx. \quad (140)$$

Now, we recall that $\zeta_\kappa(\tau, x) = x + e^{-\tau} \bar{x}_\kappa + (1 - e^{-\tau}) \mu_\kappa$, and thus obtain

$$\int_\Omega \chi \tilde{W}_\kappa^{a+m} |\mathcal{I}_1|^2 \, dx \lesssim \delta^{2a} e^{-2\tau} \int_\Omega \chi \tilde{W}_\kappa^{a+m} \left| A^m \partial^m \theta_\kappa \right|^2 \, dx$$

$$+ \delta^{2a} e^{-2\tau} \int_\Omega \chi \tilde{W}_\kappa^{a+m} \left| A^m \partial^m (x + e^{-\tau} \bar{x}_\kappa + (1 - e^{-\tau}) \mu_\kappa) \right|^2 \, dx$$

$$\lesssim \delta^{2a} e^{-2\tau} (1 + S_M(\tau)) + \delta^{2a} e^{-2\tau} (1 - e^{-\tau}) \int_\Omega \chi \tilde{W}_\kappa^{a+m} \left| A^m \partial^m \mu_\kappa \right|^2 \, dx. \quad (141)$$

Note that $e^{-\tau} \bar{x}_\kappa$ disappears under the application of spatial derivatives, and the identity function $x$ is smooth so we can bound derivatives of this term in $L^\infty(\Omega)$. We bound the $\theta_\kappa$ term by the cumulative energy function $S_M$. It remains to bound the $\mu_\kappa$ on the right hand side. Since $m + |n| > 0$, using (88) and (89), we have

$$\delta^{2a} e^{-2\tau} (1 - e^{-\tau}) \int_\Omega \chi \tilde{W}_\kappa^{a+m} \left| A^m \partial^m \mu_\kappa \right|^2 \, dx \lesssim \delta^{2a} e^{-2\tau} \sum_{a + |b| = 0}^{m + |n|} \int_\Omega \chi \tilde{W}_\kappa^{a+m} \left| A^a \partial^b \nabla \mu_\kappa \right|^2 \, dx.$$
\[ \delta^2 e^{-2\tau} \parallel \nabla \mu_k \parallel_{X^M}^2 \lesssim \delta^2 e^{-2\tau} \quad (142) \]

utilising the smallness assumption on \( \nabla \mu_k \) in \( X^M \) from (117).

Combining bounds (141) and (142) and applying a priori assumption (119), we obtain

\[ \int_\Omega \chi \hat{W}_k^{a} |I_1|^2 \, dx \lesssim \delta^2 e^{-2\tau} (1 + S_M(\tau)) \lesssim \delta^2 e^{-2\tau}. \quad (143) \]

**Bound for \( I_2 \).**

As \( m + |n| \geq 1 \), we write \( \Lambda^m \hat{p}^m \left( |\xi_k(x) - \xi_{k'}(\tau,z)|^{-3} \right) \) as

\[ \sum_{p=1}^{m+|n|} \sum_{\substack{a+|b|+|n|+|d|=p \atop a,b,d \in \mathbb{N}}} \Lambda^a \hat{p}^a \left( (A_{\xi_k} \cdot (\xi_k - \xi_{k'}))^c (\hat{b}_{12} \xi_k \cdot (\xi_k - \xi_{k'}))^d_1 (\hat{b}_{13} \xi_k \cdot (\xi_k - \xi_{k'}))^d_2 \right). \]

Thus to bound \( \Lambda^m \hat{p}^m (|\xi_k(x) - \xi_{k'}(z)|^{-3}) \) effectively, it is enough to bound each of the terms in the sum separately, for every valid choice of \( p, a, b, c, d_{12}, d_{23}, \) and \( d_{13} \). Strictly speaking the correct expansion would include varying constants in front of every term in (144) depending on each index being summed over. They have all been set to 1 as they are not important when finding sufficient bounds for each term.

We can write every separate term in (144) as

\[ \sum_{i} \frac{1}{|\xi_k - \xi_{k'}|^{3+2p}} \prod_{i=1}^{c} \Lambda^{a_i} \hat{p}^{b_i} \left( \Lambda \xi_k \cdot (\xi_k - \xi_{k'}) \right) \]

\[ \prod_{l \in \{12,23,13\}} \prod_{1 \leq i \leq d_{lq}} \Lambda^{a_i^{(lq)}} \hat{p}^{b_i^{(lq)}} \left( \hat{b}_{1lq} \xi_k \cdot (\xi_k - \xi_{k'}) \right), \quad (145) \]

where, once again, constants in front of each term in the sum have been set to 1. For any of the \( c, d_{12}, d_{23} \) or \( d_{13} \) equal to 0, the product above is an empty product, equal to 1.

Finally we can expand the derivatives above to see that (145) can be written as a linear combination of terms of the form

\[ |\xi_k - \xi_{k'}|^{-(3+2p)} \prod_{i=1}^{c} \left( \Lambda^{a_i} \hat{p}^{b_i} \xi_k \cdot (\xi_k - \xi_{k'}) \right) \]

\[ \prod_{l \in \{12,23,13\}} \prod_{i=1}^{d_{lq}} \left( \Lambda^{a_i^{(lq)}} \hat{p}^{b_i^{(lq)}} \xi_k \cdot (\xi_k - \xi_{k'}) \right), \quad (146) \]

subject to the condition that

\[ a_i + \sum_{lq} |b_i^{(lq)}| = a_i + |b_i|, \quad (147) \]

\[ a_i^{(lq)} + |b_i^{(lq)}| = a_i + |b_i|, \quad l \in \{12,23,13\}. \quad (148) \]
Thus we see that

\[
\sum_{i=1}^{c} (a_{1i} + |b_{1i}| + a_{2i} + |b_{2i}|) + \sum_{lq \in \{12,23,13\}} \sum_{i=1}^{d_{lq}} (a_{1i}^{(lq)} + |b_{1i}^{(lq)}| + a_{2i}^{(lq)} + |b_{2i}^{(lq)}|) = a + |h| = m + |n| - p. \tag{149}
\]

Then, choosing a term of the form of (146), the corresponding integral we look at has the initial bound

\[
\left| \int_{\Omega} (\zeta_k - \zeta_{k'}) \tilde{W}_k^{\alpha} \prod_{i=1}^{c} \left( \Lambda^{a_{1i}+1} \theta_{1i}^{a_{1i}} \zeta_k \cdot \Lambda^{a_{2i}} \theta_{2i}^{a_{2i}} (\zeta_k - \zeta_{k'}) \right) \prod_{lq \in \{12,23,13\}} \prod_{i=1}^{d_{lq}} \left( \Lambda^{a_{1i}^{(lq)}} \theta_{1i}^{a_{1i}^{(lq)}} \theta_{1q} \zeta_k \cdot \Lambda^{a_{2i}^{(lq)}} \theta_{2i}^{a_{2i}^{(lq)}} (\zeta_k - \zeta_{k'}) \right) dz \right|^2 \leq \int_{\Omega} \tilde{W}_k^{2\alpha} |\zeta_k - \zeta_{k'}|^{-(4+4p)} |\Lambda^{a_{1} \theta_{1}^{a_{1}} \zeta_k}|^2 \ldots |\Lambda^{a_{p_1} \theta_{p_1}^{a_{p_1}} \zeta_k}|^2 |\zeta_k - \zeta_{k'}|^{2(2p-p_1)} \, dz \leq |\Lambda^{a_{1} \theta_{1}^{a_{1}} \zeta_k}|^2 \ldots |\Lambda^{a_{p_1} \theta_{p_1}^{a_{p_1}} \zeta_k}|^2. \tag{150}
\]

For this bound, we first use the $L^2(\Omega)$ Cauchy-Schwartz on the $z$ integral over $\Omega$. Then, using Cauchy-Schwartz over $\mathbb{R}^3$, we obtain

\[
|\Lambda^{e} \theta_{e}^{f} \zeta_k \cdot \Lambda^{g} \theta_{g}^{h} (\zeta_k - \zeta_{k'})| \leq |\Lambda^{e} |\theta_{e}^{f} \zeta_k| \cdot |\Lambda^{g} \theta_{g}^{h} (\zeta_k - \zeta_{k'})| \tag{151}
\]

From here, to get an upper bound as on the second line in (150), notice that if $g + |h| \geq 1$, then

\[
\Lambda^{g} \theta_{g}^{h} (\zeta_k - \zeta_{k'}) = \Lambda^{g} \theta_{g}^{h} \zeta_k.
\]

Thus once we bound all terms of the form $\Lambda^{e} \theta_{e}^{f} \zeta_k \cdot \Lambda^{g} \theta_{g}^{h} (\zeta_k - \zeta_{k'})$ using (151), from the resulting upper bound we can collect the $p_1$ terms that look like $|\Lambda^{a_{p_1} \theta_{p_1}^{a_{p_1}} \zeta_k}|$, and the $2p - p_1$ terms that look like $|\zeta_k - \zeta_{k'}|$.

For the final bound in (150), we first note that we can bound

\[
\tilde{W}_k^{2\alpha} |\zeta_k - \zeta_{k'}|^{-(4+4p)} |\zeta_k - \zeta_{k'}|^{2(2p-p_1)} \equiv \tilde{W}_k^{2\alpha} |\zeta_k - \zeta_{k'}|^{-(4+4p_1)}
\]

in $L^\infty(\Omega)$. Indeed, we know $\tilde{W}_k$ is in $L^\infty(\Omega)$ for all $k$, and the negative power of $|\zeta_k - \zeta_{k'}|$ can be bounded using the Strong Separation Condition (118) as in (137). The remaining terms in the product under the $z$ integral on the second line of (150), $|\Lambda^{a_{1} \theta_{1}^{a_{1}} \zeta_k}|^2 \ldots |\Lambda^{a_{p_1} \theta_{p_1}^{a_{p_1}} \zeta_k}|^2$, have no $z$ dependence, and can therefore be taken out of integral, leading to the last bound in (150). Therefore, to bound $I_2$ effectively, it remains to bound all integrals of the form

\[
\delta^{2\alpha} e^{-2\tau} \int_{\Omega} \chi \tilde{W}_k^{\alpha+m} \left| \Lambda^{a_{1} \theta_{1}^{a_{1}} \zeta_k} \right|^2 \ldots \left| \Lambda^{a_{p_1} \theta_{p_1}^{a_{p_1}} \zeta_k} \right|^2 dx. \tag{152}
\]
for $1 \leq a_1 + |b_1| \leq \ldots \leq a_{p_1} + |b_{p_1}| \leq m + |n|$. We write

$$\delta^2 e^{-2\tau} \int \omega \tilde{W}^{\alpha+m} \left| A_{\alpha}^{1} \partial_{\xi}^{b_1} \xi_k \right|^2 \ldots \left| A_{\alpha}^{p_1} \partial_{\xi}^{b_{p_1}} \xi_k \right|^2 dx$$

$$= \delta^2 e^{-2\tau} \int \omega \tilde{W}^{m} \sum_{\alpha} \tilde{W}^{a_1} \left| A_{\alpha}^{1} \partial_{\xi}^{b_1} \xi_k \right|^2 \ldots \tilde{W}^{a_{p_1}} \left| A_{\alpha}^{p_1} \partial_{\xi}^{b_{p_1}} \xi_k \right|^2 dx.$$  

(153)

For $i = 1, \ldots, p_1 - 1$, we have $a_i + |b_i| \leq a_{p_1} + |b_{p_1}|$, and therefore $a_i + |b_i| \leq (m + |n|)/2 \leq M/2$. Thus, we can apply (231) from Lemma 8 to $\tilde{W}^{a_i} \left| A_{\alpha} \partial_{\xi}^{b} \xi_k \right|^2$ for $i = 1, \ldots, p_1 - 1$, and bound these terms in $L^\infty(\Omega)$. We obtain

$$\delta^2 e^{-2\tau} \int \omega \tilde{W}^{m} \sum_{\alpha} \tilde{W}^{a_i} \left| A_{\alpha}^{1} \partial_{\xi}^{b_1} \xi_k \right|^2 \ldots \tilde{W}^{a_{p_1}} \left| A_{\alpha}^{p_1} \partial_{\xi}^{b_{p_1}} \xi_k \right|^2 dx$$

$$\leq \delta^2 e^{-2\tau} (1 + S_M(\tau))^{p_1 - 1} \int \omega \tilde{W}^{m} \sum_{\alpha} \tilde{W}^{a_1} \left| A_{\alpha}^{1} \partial_{\xi}^{b_1} \xi_k \right|^2 \ldots \tilde{W}^{a_{p_1}} \left| A_{\alpha}^{p_1} \partial_{\xi}^{b_{p_1}} \theta_k \right|^2 dx$$

$$+ \delta^2 e^{-2\tau} (1 + S_M(\tau))^{p_1 - 1} \int \omega \tilde{W}^{m} \sum_{\alpha} \tilde{W}^{a_1} \left| A_{\alpha}^{1} \partial_{\xi}^{b_1} (x + e^{-\tau} \xi_k + (1 - e^{-\tau}) \mu_k (x)) \right|^2 dx.$$  

(154)

The $\theta_k$ term on the right hand side can be bounded by the cumulative energy function $S_M$. For the remaining term, we use (142) to bound the $\mu_k$ term, and note that we can bound $\tilde{W}^{m} \sum_{\alpha} \xi_k$ in $L^\infty(\Omega)$, as $\sum a_i \leq m$. Thus we obtain

$$\delta^2 e^{-2\tau} \int \omega \tilde{W}^{m} \sum_{\alpha} \tilde{W}^{a_1} \left| A_{\alpha}^{1} \partial_{\xi}^{b_1} \xi_k \right|^2 \ldots \tilde{W}^{a_{p_1}} \left| A_{\alpha}^{p_1} \partial_{\xi}^{b_{p_1}} \xi_k \right|^2 dx$$

$$\leq \delta^2 e^{-2\tau} (1 + S_M(\tau))^{p_1}$$

$$\leq \delta^2 e^{-2\tau},$$  

(155)

where the last bound is due to the a priori assumption (119). Thus we have

$$\int \omega \tilde{W}^{\alpha+m} |I_2|^2 dx \leq \delta^2 e^{-2\tau},$$  

(156)

as required.

**Bound for $I_3$.**

Similarly to $I_2$, to bound any of the terms in the sum that forms $I_3$ it is sufficient to bound all terms of the form

$$\delta^2 e^{-2\tau} \int \omega \tilde{W}^{\alpha+m} \left| A_{\alpha} \partial_{\xi}^{b_1} \xi_k \right|^2 \ldots \left| A_{\alpha} \partial_{\xi}^{b_{p_1}} \xi_k \right|^2 \left| A_{\alpha} \partial_{\xi}^{b_{p_1}} \xi_k \right|^2 dx,$$  

(157)

subject to the condition that $a + \sum a_i = m$, and $|b| + \sum |b_i| = |n|$. This requires exactly the same strategy as (154), and so we immediately obtain

$$\int \omega \tilde{W}^{\alpha+m} |I_3|^2 dx \leq \delta^2 e^{-2\tau}. $$  

(158)
The bounds in (141), (156), and (158), along with analogous estimates on \( \text{supp} \, \chi \), give the proposition.

Now we move on to estimates for the gravitational potentials acting on each separate body coming from their own mass.

### 7.2. Self interaction term estimates

In this section we estimate the term coming from the gravitational effect of a body in this system on itself, \( G_\kappa \). Let us recall that we can write

\[
G_\kappa^i(\tau, x) = \delta^a e^{-\tau} \int_\Omega \frac{\partial_k \left( \hat{W}_\kappa^a \kappa A[\kappa] \right)}{|\xi_\kappa(\tau, x) - \xi_\kappa(\tau, z)|} \, dz.
\]  

(159)

The key estimate for \( G_\kappa \) is laid out in the following proposition.

**Proposition 2.** Assume \( \gamma = 1 + \frac{1}{n} \) for some \( n \in \mathbb{Z}_{\geq 2} \), or \( \gamma \in (1, 14/13) \). Let \( \{ (\partial_\tau \theta_\kappa, \theta_\kappa) | \kappa = 1, 2, \ldots, N \} \) be the solution to (72)–(74) on \([0, T]\), in the sense of Theorem 2, for some \( M \geq 2 \left\lceil \alpha - \frac{1}{3} \right\rceil \). Suppose the assumptions (117)–(122) hold. Assume that \( \nabla \hat{W}_\kappa \in \mathcal{X}_M^M \) for \( \kappa = 1, 2, \ldots, N \). Then for all \( \tau \in [0, T] \), we have:

\[
\sum_{\kappa=1}^{N} \left( \sum_{m+|n|=0} \int_\Omega \chi \hat{W}_\kappa^{a+m} |A^m \hat{\theta}_\kappa \theta_\kappa|^2 \, dx + \sum_{|k|=0}^{M} \int_\Omega \hat{W}_\kappa^a |\nabla^k \theta_\kappa|^2 \, dx \right) \lesssim \delta^{2\alpha} e^{-2\tau}.
\]  

(160)

We begin with estimates for the integrals near the boundary, on \( \text{supp} \, \chi \). The strategy follows the strategy in [32]. We first bound tangential derivatives of \( \mathcal{G} \), and use these, as well as the Poisson equation \( \Delta \phi = \rho \), to close estimates in the normal direction. The estimates for tangential derivatives of \( \mathcal{G}_\kappa \) near the boundary are stated in the following proposition:

**Proposition 3.** (Tangential self-interaction estimates) Assume \( \gamma = 1 + \frac{1}{n} \) for some \( n \in \mathbb{Z}_{\geq 2} \), or \( \gamma \in (1, 14/13) \). Let \( \{ (\partial_\tau \theta_\kappa, \theta_\kappa) | \kappa = 1, 2, \ldots, N \} \) be the solution to (72)–(74) on \([0, T]\), in the sense of Theorem 2, for some \( M \geq 2 \left\lceil \alpha - \frac{1}{3} \right\rceil \). Suppose the assumptions (117)–(122) hold. Assume that \( \nabla \hat{W}_\kappa \in \mathcal{X}_M^M \) for \( \kappa = 1, 2, \ldots, N \). Then for all \( \tau \in [0, T] \), we have:

\[
\sum_{\kappa=1}^{N} \sum_{|n|=0}^{M} \int_\Omega \chi \hat{W}_\kappa^a |\hat{\theta}_\kappa \theta_\kappa|^2 \, dx \lesssim \delta^{2\alpha} e^{-2\tau}.
\]  

(161)

**Proof.** The proof relies on the following lemma, which was first used by Gu and Lei [26] in the context of the spatial domain being \( \mathbb{T}^2 \times \mathbb{R} \) rather than the closed unit ball. It was then adapted in to our setting by Hadži´c and Jang [32]. For a full proof of the proposition, see [32], whose methods apply directly to our case. □
Lemma 1. Let $\partial_x$ and $\partial_z$ denote angular derivatives in the $x$ and $z$ variables respectively. Let $h_1 : \mathbb{R}^3 \to \mathbb{R}$, and $h_2 : \mathbb{R}^3 \times \mathbb{R}^3 \to \mathbb{R}$. Let $\nu \in \mathbb{Z}^3_{\geq 0}$. Then

$$\partial^{\nu} x \int_{\Omega} h_1(z) h_2(x, z) dz = \sum_{|\nu'| \leq |\nu|} c_{\nu'} \int_{\Omega} \partial^{\nu'-\nu} x (\partial_x + \partial_z)^{\nu'} h_2 dz,$$

for some constants $c_{\nu'}$.

Proof. The proof is a combination of the identity $\partial_x = (\partial_x + \partial_z) - \partial_z$, as well as integration by parts in the $z$ variable. $\square$

We now use Proposition 3 to prove Proposition 2. Once again, the proof strategy very closely follows that of the one in [32].

Proof of Proposition 2. Recall that we are looking to prove

$$\sum_{\kappa=1}^{N} \left( \sum_{m+|\ell|=0}^{M} \int_{\Omega} \chi \tilde{W}^{\alpha + m} \left| A^m \partial^{\ell} g_{\kappa} \right|^2 dx + \sum_{|\ell|=0}^{M} \int_{\Omega} \tilde{\chi} \tilde{W}^{\alpha} \left| \nabla^{k} g_{\kappa} \right|^2 dx \right) \lesssim \delta^{2\alpha} e^{-2\tau}.$$

(163)

We first concentrate on the interior bounds, localised on supp $\tilde{\chi}$. Recall the definition of $\chi$ and $\tilde{\chi}$ as smooth radial cutoff functions in (100) and (101). We know that supp $\tilde{\chi} = B_{3/4}$, the ball of radius $3/4$ around 0. Define another smooth radial function $\tilde{\chi}_v$ such that

$$\text{supp } \tilde{\chi}_v = B_{\frac{3}{4} + v}$$

such that $\frac{3}{4} + v \in (3/4, 1)$. Correspondingly we define

$$\chi_v = 1 - \tilde{\chi}_v.$$

(165)

To bound the integrals on supp $\tilde{\chi}$ we have

$$\sum_{\kappa=1}^{N} \sum_{|\ell|=0}^{M} \int_{\Omega} \tilde{\chi} \tilde{W}^{\alpha} \left| \nabla^{k} g_{\kappa} \right|^2 dx \lesssim \delta^{2\alpha} e^{-2\tau} \sum_{\kappa=1}^{N} \sum_{|\ell|=0}^{M} \int_{\Omega} \tilde{\chi} \tilde{W}^{\alpha} \left| \nabla^{k} g_{\kappa} \right|^2 dx \lesssim \delta^{2\alpha} e^{-2\tau} \sum_{\kappa=1}^{N} \sum_{|\ell|=0}^{M} \int_{\Omega} \tilde{\chi} \tilde{W}^{\alpha} \left| \nabla^{k} g_{\kappa} \right|^2 dx.$$

(166)

For the first term on the right hand side above, we can use the methods we used in Proposition 1 as

$$0 < v \leq |x - z| \lesssim |\zeta_k(\tau, x) - \zeta_k(\tau, z)|$$
for \(x \in \text{supp} \bar{\chi}, z \in \text{supp} \chi_v\), using the mean value theorem and (120). For the second term we can use the same methods as Proposition 3, noting that \(\bar{\chi}_v\) and its derivatives are 0 on \(\partial \Omega\), so there are no boundary terms when we integrate by parts to get an identity analogous to Lemma 1. Therefore, we have

\[
\sum_{\kappa=1}^{N} \sum_{|k|=0}^{M} \int_{\Omega} \bar{\chi} \hat{W}_k^\alpha \left| \nabla_k^\alpha \varphi_k \right|^2 \, dx \lesssim \delta^{2\alpha} e^{-2\tau}.
\]

(167)

Now we concentrate on the \(\text{supp} \chi\) bounds. As in [32], we use induction on the number of radial derivatives. For now we fix a \(\kappa\). Our induction hypothesis is

\[
\sum_{|n| \leq M-a} \int_{\Omega} \chi \hat{W}_k^{\alpha+a} \left| A^a \varphi_k \right|^2 \, dx \leq C(a) \left( \delta^{2a} e^{-2\tau} + (\epsilon_1 + \epsilon_2) \| \varphi_k \|_{X^M}^2 \right),
\]

(168)

where \(C(a)\) is a constant depending only on the number of radial derivatives and our a priori assumptions (117)–(121), and \(\epsilon_1, \epsilon_2\) are the constants mentioned in the a priori assumptions, Section 6.2. The case where \(m = 0\) has been dealt with in Proposition 3. Now assume it holds for some \(0 < a < M\). Following [32], we use the Poisson equation (22) to write \(A\varphi_k\) in a form amenable to the necessary estimates.

Recall that (22) gives us the relation \(\Delta \varphi = 4\pi \rho\), and we know from (15) that \(\rho\) is the cumulative density defined by \(\rho = \sum \rho_k\), so, where \(\rho, \{\rho_k\}\) are thought of as functions on \(\mathbb{R}^3\) with compact support, we can define \(\varphi_k\) to be the solution to

\[
\Delta \varphi_k = 4\pi \rho_k
\]

(169)
on \(\mathbb{R}^3\), with \(\varphi_k \to 0\) as \(|x| \to \infty\) as the boundary condition. We know that \(\varphi_k = \Phi * \rho_k\), where \(\Phi\) is the fundamental solution, so in Lagrangian coordinates we have

\[
\mathcal{A}[k] \partial_k \varphi_k (t, \eta_k (t, x)) = -\varphi_k^l,
\]

(170)

where we recall the definition of \(\varphi_k\) from (63). We take the Lagrangian divergence of this relationship, and comparing to the pullback via \(\eta_k\) of (169), obtain

\[
\text{div}_{\xi} \varphi_k = \mathcal{A}[k]^l \partial_l \varphi_k^l = 4\pi \rho_k (t, \eta_k (t, x)).
\]

(171)

Then, using (43, (47), (51)), and (54), we have

\[
\text{div}_{\xi} \varphi_k = 4\pi \delta^a e^{-3\tau} \hat{W}_k^\alpha \varphi_k^{-1}.
\]

(172)

Moreover, since \(\varphi_k\) can be written as the Lagrangian gradient of some potential function, we immediately have

\[
\text{Curl}_{\xi} \varphi_k = 0.
\]

(173)

Now we define \(\mathcal{R}_k\):

\[
\mathcal{R}_k (\tau, x) = e^{-\tau} \bar{x}_k + (1 - e^{-\tau}) \mu_k (x) + \vartheta_k (\tau, x) = \xi_k (\tau, x) - x.
\]

(174)
With this definition of $\mathcal{R}_k$ we have
\[
\text{div } \mathcal{G}_k = \delta^a e^{-3\tau} \tilde{W}_k^\alpha \mathcal{J}_k^{-1} + \mathcal{A} [\kappa]_j^k \partial_j \mathcal{R}_k^i \
\text{curl } \mathcal{G}_k^i = \mathcal{A} [\kappa]_j^k \partial_j \mathcal{R}_k^i - \mathcal{A} [\kappa]_i^k \partial_i \mathcal{R}_k^j. \tag{175}
\]

We also have
\[
y^i \text{ div } \mathcal{G}_k = \partial_i \mathcal{G}_k^i + y^k \partial_k \mathcal{G}_k^k
= \partial_i \mathcal{G}_k^i + y^k [\text{Curl } \mathcal{G}_k]^i + y^k \partial_k \mathcal{G}_k^i = \partial_i \mathcal{G}_k^i + y^k [\text{Curl } \mathcal{G}_k]^i + \Lambda \mathcal{G}_k^i. \tag{177}
\]

Thus
\[
\Lambda \mathcal{G}_k^i = y^i \text{ div } \mathcal{G}_k - y^k [\text{Curl } \mathcal{G}_k]^i - \partial_i \mathcal{G}_k^i. \tag{178}
\]

Then, using (178) and the commutativity of $\Lambda$ and $\partial$, we obtain
\[
\sum_{0 \leq |\xi| \leq M-a-1} \int_\Omega \chi \tilde{W}_k^{\alpha+a+1} \left| \Lambda^{\alpha+1} \mathcal{A} \mathcal{G}_k \right|^2 dx
= \sum_{0 \leq |\xi| \leq M-a-1} \int_\Omega \chi \tilde{W}_k^{\alpha+a+1} \left| \Lambda^a \mathcal{A} \mathcal{G}_k \right|^2 dx
\sum_{0 < b \leq a} \int_\Omega \chi \tilde{W}_k^{\alpha+a+1} \left( \left| \Lambda^b \mathcal{A} \text{ div } \mathcal{G}_k \right|^2 + \left| \Lambda^b \mathcal{A} \text{ Curl } \mathcal{G}_k \right|^2 \right) dx
+ \sum_{0 \leq |\xi| \leq M-a-1} \int_\Omega \chi \tilde{W}_k^{\alpha+a} \left| \Lambda^a \mathcal{A} \mathcal{G}_k \right|^2 dx
\sum_{0 < b \leq a} \int_\Omega \chi \tilde{W}_k^{\alpha+a+1} \left( \left| \Lambda^b \mathcal{A} \text{ div } \mathcal{G}_k \right|^2 + \left| \Lambda^b \mathcal{A} \text{ Curl } \mathcal{G}_k \right|^2 \right) dx + C(a) \left( \delta^{2a} e^{-2\tau} + (\varepsilon_1 + \varepsilon_2) \| \mathcal{G}_k \|_{X_M}^2 \right). \tag{179}
\]

The first bound is due to (178) and the second is due to the induction hypothesis (168). It is left to estimate the div $\mathcal{G}_k$ and Curl $\mathcal{G}_k$ terms. For this we use (175) and (176). First we have
\[
\sum_{0 < b \leq a} \int_\Omega \chi \tilde{W}_k^{\alpha+a+1} \left| \Lambda^b \mathcal{A} \left( \delta^a e^{-3\tau} \tilde{W}_k^\alpha \mathcal{J}_k^{-1} \right) \right|^2 dx
\lesssim \delta^{2a} e^{-6\tau} \sum_{0 \leq a_1 + |b_1| \leq a_2 + |b_2|, 0 < a_1 + a_2 \leq a} \| \tilde{W}_k^{a_1} \Lambda^{a_1} \mathcal{A}^{b_1} (\tilde{W}_k^\alpha) \|_{L^\infty(\Omega)}^2. \]
\[
\int_{\Omega} \chi \tilde{W}_k^\alpha + a + 1 \left| A^{a_2} \tilde{g}^{b_2} (J^{-1}_k) \right|^2 \, dx \\
+ \delta^2 a e^{-6\tau} \sum_{0 \leq a_1 + |b_1| \leq a_2 + |b_2|} \sum_{0 < a_1 + a_2 + a \leq a} \int_{\Omega} \chi \tilde{W}^{a_1}_k A^{a_1} \tilde{g}^{b_1} (J^{-1}_k) \right|^2 \, dx \\
\lesssim \delta^2 a e^{-6\tau} \sum_{0 \leq |a| \leq \frac{M}{2} - a - 1} \sum_{0 \leq a_1 + |b_1| \leq a_2 + |b_2|} \sum_{0 < a_1 + a_2 + a \leq a} \int_{\Omega} \chi \tilde{W}^{a_1}_k A^{a_1} \tilde{g}^{b_1} (J^{-1}_k) \right|^2 \, dx \\
+ \delta^2 a e^{-6\tau} \sum_{0 \leq a_1 + |b_1| \leq a_2 + |b_2|} \sum_{0 < a_1 + a_2 + a \leq a} \int_{\Omega} \chi \tilde{W}^{a_1}_k A^{a_1} \tilde{g}^{b_1} (J^{-1}_k) \right|^2 \, dx \\
\lesssim \delta^2 a e^{-6\tau} \int_{\Omega} \chi \tilde{W}^{a_1}_k A^{a_1} \tilde{g}^{b_1} (J^{-1}_k) \right|^2 \, dx.
\] (180)

If \( a_1 + |b_1| = 0 \) then both \( \tilde{W}^\alpha \), and \( J^{-1}_k \) can bounded in \( L^\infty(\Omega) \), due to the assumption that \( \nabla \tilde{W}^\alpha \in \mathcal{X}_M^k \) and the a priori assumption \( (121) \) respectively. Otherwise, we first use \( (220) \) (resp. \( (221) \)) from Lemma 3 to bound the terms involving \( L^2 \) (resp. \( L^\infty \)) norms of derivatives of \( J^{-1}_k \). Then for the \( \tilde{W}^\alpha_k \) terms, we can use \( \nabla \tilde{W}^\alpha_k \in \mathcal{X}_M^k \) (resp. \( (232) \) in Lemma 8) to bound the \( L^2 \) (resp. \( L^\infty \)) terms after using the Leibniz rule on \( A^{a_1} \tilde{g}^{b_2} (\tilde{W}^\alpha_k) \). Note here that our range of \( \gamma \) is crucial in keeping the norms of the derivatives of \( \tilde{W}^\alpha_k \) finite. Next we have

\[
\sum_{0 \leq a_1 + |b_1| \leq a_2 + |b_2|} \sum_{0 < a_1 + a_2 + a \leq a} \int_{\Omega} \chi \tilde{W}^{a_1}_k A^{a_1} \tilde{g}^{b_1} (J^{-1}_k) \right|^2 \, dx \\
\lesssim \delta^2 a e^{-6\tau} \sum_{0 \leq a_1 + |b_1| \leq a_2 + |b_2|} \sum_{0 < a_1 + a_2 + a \leq a} \int_{\Omega} \chi \tilde{W}^{a_1}_k A^{a_1} \tilde{g}^{b_1} (J^{-1}_k) \right|^2 \, dx \\
+ \delta^2 a e^{-6\tau} \sum_{0 \leq a_1 + |b_1| \leq a_2 + |b_2|} \sum_{0 < a_1 + a_2 + a \leq a} \int_{\Omega} \chi \tilde{W}^{a_1}_k A^{a_1} \tilde{g}^{b_1} (J^{-1}_k) \right|^2 \, dx \\
+ \delta^2 a e^{-6\tau} \sum_{0 \leq a_1 + |b_1| \leq a_2 + |b_2|} \sum_{0 < a_1 + a_2 + a \leq a} \int_{\Omega} \chi \tilde{W}^{a_1}_k A^{a_1} \tilde{g}^{b_1} (J^{-1}_k) \right|^2 \, dx.
\] (181)
The terms involving $L^2$ (resp. $L^\infty$) norms of derivatives of $\mathscr{A}[\kappa]$ can be bounded using (220) (resp. (221)) in Lemma 3. For the $\mathscr{G}_k$ terms, we have for $i = 1, 2$:

$$\int_\Omega \chi \tilde{W}^{a_3+a_1+1}_k \left| A^{a_3} \tilde{b}^{b_3} (\nabla \mathcal{G}_k) \right|^2 \, dx \lesssim \sum_{c+|d|=1} \int_\Omega \chi \tilde{W}^{a+c+1}_k \left| A^{c} \tilde{d}^d (\mathcal{G}_k) \right|^2 \, dx \lesssim \| \mathcal{G}_k \|^2_{\mathcal{X}_M^\kappa},$$  

(182)

$$\left\| \tilde{W}^{a_i}_k \right\|_{L^\infty(\Omega)}^2 \lesssim \sum_{c+|d|=1} \left\| \tilde{W}^{a_i}_k \right\|_{L^\infty(\Omega)}^2 \lesssim \| \mathcal{G}_k \|^2_{\mathcal{X}_M^\kappa}.$$  

(183)

In (182) we use (90), and in (183) we use (90) and (231) in Lemma 8. The $\mathcal{R}_k$ terms can be bounded analogously to (182) and (183). Thus

$$\sum_{0 < b \leq a \leq M-1} \int_\Omega \chi \tilde{W}^{a+b+1}_k \left| A^{b} \tilde{d}^d (\mathcal{A}[\kappa] \nabla \mathcal{R}_k \nabla \mathcal{G}_k) \right|^2 \, dx \lesssim \left( S_M(\tau) + \| \nabla \mu_k \|^2_{\mathcal{X}_M^\kappa} \right) \| \nabla \mathcal{G}_k \|^2_{\mathcal{X}_M^\kappa} \lesssim (\varepsilon_1 + \varepsilon_2) \| \mathcal{G}_k \|^2_{\mathcal{X}_M^\kappa}.$$  

(184)

Then, from the identities for $\text{div} \mathcal{G}_k$ and $\text{Curl} \mathcal{G}_k$ given in (175) and (176), as well as (179)–(184), we have

$$\sum_{0 \leq |n| \leq M-a-1} \int_\Omega \chi \tilde{W}^{a+n+1}_k \left| A^{n} \tilde{d}^d \mathcal{G}_k \right|^2 \, dx = \sum_{0 \leq |n| \leq M-a-1} \int_\Omega \chi \tilde{W}^{a+n+1}_k \left| A^{n} \tilde{d}^d \mathcal{G}_k \right|^2 \, dx \leq C(a + 1) \left( \delta^{2\alpha} e^{-2\tau} + (\varepsilon_1 + \varepsilon_2) \| \mathcal{G}_k \|^2_{\mathcal{X}_M^\kappa} \right),$$  

(185)

for some constant $C(a + 1)$. This proves the induction hypothesis.

Clearly the sum all of the $C(a)$ can be bounded above by an absolute constant that we call $C_1$, and so summing these bounds for all $a$, we obtain

$$\sum_{m+|l|=0} \int_\Omega \chi \tilde{W}^{a+m}_k \left| A^{m} \tilde{d}^d \mathcal{G}_k \right|^2 \, dx \leq C_1 \left( \delta^{2\alpha} e^{-2\tau} + (\varepsilon_1 + \varepsilon_2) \| \mathcal{G}_k \|^2_{\mathcal{X}_M^\kappa} \right).$$  

(186)

Combining (186) and (167), we have, for some constant $C_2$,

$$\sum_{m+|l|=0} \int_\Omega \chi \tilde{W}^{a+m}_k \left| A^{m} \tilde{d}^d \mathcal{G}_k \right|^2 \, dx + \sum_{|l|=0} \int_\Omega \tilde{W}^{a}_k \left| \nabla \mathcal{G}_k \right|^2 \, dx \leq C_2 \left( \delta^{2\alpha} e^{-2\tau} + (\varepsilon_1 + \varepsilon_2) \| \mathcal{G}_k \|^2_{\mathcal{X}_M^\kappa} \right).$$  

(187)
Recall in Section 6.2 we defined $\varepsilon_1$ and $\varepsilon_2$ as small constants that could be shrunk if necessary. Upon doing this, and recalling the definition of $\mathcal{X}_\kappa^M$ norm from Definition 2, we have

$$
\sum_{m+|\mu|=0}^{M} \int_{\Omega} \chi \tilde{W}_\kappa^{\alpha+m} \left| \Lambda^m \partial^{\alpha \mu} \tilde{g}_\kappa \right|^2 \, dx + \sum_{|\nu|=0}^{M} \int_{\Omega} \tilde{X} \tilde{W}_\kappa^{\alpha} \left| \nabla^{\nu} \tilde{g}_\kappa \right|^2 \, dx \lesssim \delta^{2\alpha} e^{-2\tau}.
$$

(188)

Summing over $\kappa$ for (188) gives (163), and completes the proof of Proposition 2. $\Box$

7.3. Potential term estimates

We end this section with the main estimate needed to bound all potential terms when we perform our energy estimates.

**Theorem 4.** Assume $\gamma = 1 + \frac{1}{n}$ for some $n \in \mathbb{Z}_{\geq 2}$, or $\gamma \in (1, 14/13)$. Let $\{(\partial_\tau \theta_\kappa, \theta_\kappa)\}_{\kappa = 1, 2, \ldots, N}$ be the solution to (72)–(74) on $[0, T]$, in the sense of Theorem 2, for some $M \geq 2\lceil * \rceil \alpha + 12$. Suppose the assumptions (117)–(122) hold. Assume that $\nabla \tilde{W}_\kappa \in \mathcal{X}_\kappa^M$ for $\kappa = 1, 2, \ldots, N$. Then for all $[\tau_1, \tau] \subset [0, T]$, we have:

$$
\sum_{\kappa=1}^{N} \sum_{m+|\mu|=0}^{M} \int_{\tau_1}^{\tau} \frac{1}{\delta} e^{\beta s} \int_{\Omega} \chi \tilde{W}_\kappa^{\alpha+m} \Lambda^m \partial^{\alpha \mu} \left( \mathcal{A} \left[ \kappa \right]_i^j \partial_j \psi_\kappa \right) \Lambda^m \partial^{\alpha \mu} \partial_\tau \theta_\kappa^i \, dx \, ds
$$

$$
+ \sum_{\kappa=1}^{N} \sum_{|\nu|=0}^{M} \int_{\tau_1}^{\tau} \frac{1}{\delta} e^{\beta s} \int_{\Omega} \tilde{X} \tilde{W}_\kappa^\alpha \nabla^{\nu} \left( \mathcal{A} \left[ \kappa \right]_i^j \partial_j \psi_\kappa \right) \nabla^{\nu} \partial_\tau \theta_\kappa^i \, dx \, ds
$$

$$
\lesssim \delta^{\alpha - \frac{1}{2}} \int_{\tau_1}^{\tau} e^{\left( \frac{d}{2} - 1 \right) s} \sqrt{S_M(s)} \, ds.
$$

(189)

**Proof.** The proof follows from the identity (63), and Propositions 1 and 2. $\Box$

8. Curl Estimates

In this section we obtain sufficient bounds, for all $\kappa \in \{1, 2, \ldots, N\}$, of the quantities $\| \partial_\tau \theta_\kappa \|_{\mathcal{Y}_\kappa^M(\text{Curl}_{\kappa})}$ and $\| \theta_\kappa \|_{\mathcal{Y}_\kappa^M(\text{Curl}_{\kappa})}$, thereby giving us sufficient bounds for the cumulative Curl$_{\kappa}$ energy function $C_M(\tau)$ defined in (107). Common to many works regarding Euler, or Euler–Poisson flows is the difficulty of controlling the Curl$_{\kappa}$ norms mentioned above. This is due to the fact that they will appear in our main energy identity, at top order, with a bad sign. This means we need to find another way to control the Curl$_{\kappa}$ terms. This is done by noticing extra structure in the equation (59). First, note that we can rewrite this equation as

$$(\partial_\tau \theta_\kappa + \partial_\tau \theta_\kappa) + \nabla_{\kappa} \left( (1 + \alpha)e^{-\beta \tau} w_\kappa \mathcal{J}^{-1/\alpha}_\kappa + \psi_\kappa \right) = 0, \ \kappa = 1, 2, \ldots, N.
$$

(190)
From here, the key insight is to see that \( \text{Curl}_{\zeta} \) annihilates the \( \nabla_{\zeta} \) term, leaving us with
\[
\text{Curl}_{\zeta} \partial_{\tau \tau} \theta_{\kappa} + \text{Curl}_{\zeta} \partial_{\tau} \theta_{\kappa} = 0 \quad \kappa = 1, 2, \ldots, N.
\] (191)

**Remark 17.** This underlying structure of the compressible Euler equations in Lagrangian variables has been used extensively in the study of the system, see [11, 13, 31, 41] for example.

This is structurally very similar to the \( \text{Curl}_{\zeta} \) equation obtained in [65], and indeed the subsequent estimates follow an analogous strategy. Indeed, using (190) we can write
\[
\partial_{\tau} (\text{Curl}_{\zeta} \partial_{\tau} \theta_{\kappa}) + \text{Curl}_{\zeta} \partial_{\tau} \theta_{\kappa} - \left[ \partial_{\tau}, \text{Curl}_{\zeta} \right] \partial_{\tau} \theta_{\kappa} = 0,
\] (192)

where
\[
([\partial, \text{Curl}_{\zeta}] F)^i_j = \partial \left( \mathcal{A}[\kappa]^i_j \right) \partial_s F^j_i - \partial \left( \mathcal{A}[\kappa]^j_i \right) \partial_s F^i_j,
\] (193)

for \( \partial \in \{\partial_1, \partial_2, \partial_3, \partial_{\tau}\} \). Thus
\[
\text{Curl}_{\zeta} \partial_{\tau} \theta_{\kappa} = e^{-\tau} \text{Curl}_{\zeta} \partial_{\tau} \theta_{\kappa}(0) + e^{-\tau} \int_0^\tau e^s \left[ \partial_{\tau}, \text{Curl}_{\zeta} \right] \partial_{\tau} \theta_{\kappa}(s) \, ds.
\] (194)

Moreover, we know from Fundamental Theorem of Calculus that
\[
\left[ \text{Curl}_{\zeta} \theta_{\kappa} \right]^i_j(\tau) = \int_0^\tau \partial_{\tau} \left[ \text{Curl}_{\zeta} \theta_{\kappa} \right]^i_j(s) \, ds
\]
\[
= \int_0^\tau \left( \partial_{\tau} \left( \mathcal{A}[\kappa]^i_j \right) \partial_l \theta^l_{\kappa} - \partial_{\tau} \left( \mathcal{A}[\kappa]^j_i \right) \partial_l \theta^l_{\kappa} \right)
\]
\[
+ \left[ \text{Curl}_{\zeta} \partial_{\tau} \theta_{\kappa} \right]^i_j(s) \, ds.
\] (195)

Using (194) and (195), we can obtain the necessary estimates for the \( \text{Curl}_{\zeta} \) energy functions, in largely the same way as in [65]. The only important difference is that in our case, derivatives of \( \mathcal{A}[\kappa] \) and \( \mathcal{J}_{\kappa} \) when we act on the identities (194) and (195) with derivatives of the form \( \Lambda^m \theta^n \) produce derivatives of \( \mu_{\kappa} \) as well as derivatives of \( \theta_{\kappa} \). However, the derivatives of \( \mu_{\kappa} \) will always be multiplied by derivatives of \( \theta_{\kappa} \) as can be seen by the structure of the right hand sides of (194) and (195). Thus, they can be dealt with using the smallness assumption on \( \nabla \mu_{\kappa} \), (117), as the derivatives of \( \theta_{\kappa} \) will give us the powers of the cumulative energy function we need to close our final estimates. For example, we can bound a typical term which includes derivatives of \( \mu_{\kappa} \) like so:
\[
\left| \int_\Omega \chi \hat{W}_{\kappa}^{1+\alpha + m} \Lambda^m \theta^m_{\kappa} \Lambda^m \theta^m_{\kappa} \partial_{\tau} \theta^l_{\kappa} \, dx \right|^2 \lesssim \delta e^{-\beta \tau} \| \mu_{\kappa} \|^2_{L^M} S_M(\tau) \lesssim \delta e^{-\beta \tau} S_M(\tau),
\] (196)

where we use the smallness of \( \nabla \mu_{\kappa} \) in \( L^M_k \) given by (117). Hence, these novel terms are readily bounded without any further technical difficulties as compared to [65]. Therefore, using the methods in [65], we obtain the following theorem.
Theorem 5. (Higher Order Curl Estimates) Assume $\gamma = 1 + \frac{1}{n}$ for some $n \in \mathbb{Z}_{\geq 2}$, or $\gamma \in (1, 14/13)$. Let $\{ (\partial_t \theta_k, \theta_k) | k = 1, 2, \ldots, N \}$ be the solution to (72)--(74) on $[0, T]$, in the sense of Theorem 2, for some $M \geq 2 \lceil \ast \rceil \alpha + 12$. Suppose the assumptions (117)--(122) hold. Assume that $\nabla \tilde{W}_k \in \mathcal{Y}_M^\kappa$ for $k = 1, 2, \ldots, N$. Then for all $\tau \in [0, T]$, we have:

$$\sum_{\kappa=1}^{N} \left( \| \theta_k \|_{2M (\text{Curl} \alpha)}^2 + \| \partial_t \theta_k \|_{2M (\text{Curl} \alpha)}^2 \right) \lesssim S_M(0) + C_M(0) + \delta S_M(\tau). \quad (197)$$

9. Energy Estimates

In this section, we prove the main energy identity, and subsequent energy estimates that will form the bulk of the proof of Theorem 3. First we need some definitions.

Definition 5. (Damping Functional) Assume $\gamma = 1 + \frac{1}{n}$ for some $n \in \mathbb{Z}_{\geq 2}$, or $\gamma \in (1, 14/13)$. Let $\{ (\partial_t \theta_k, \theta_k) | k = 1, 2, \ldots, N \}$ be the solution to (72)--(74) on $[0, T]$, in the sense of Theorem 2, for some $M \geq 2 \lceil \ast \rceil \alpha + 12$. Define the damping functional $D(\tau)$ on $[0, T]$ by

$$D(\tau) = \frac{1}{\delta} \left( 2 - \beta \right) \sum_{\kappa=1}^{N} \left( \sum_{m+|m|=0}^{M} \int_{\Omega} e^{\beta \tau} \chi \tilde{W}_k^{\alpha + m} | \Lambda_m^{\alpha} \partial_t \theta_k |^2 dx + \sum_{|k|=0}^{M} \int_{\Omega} e^{\beta \tau} \tilde{W}_k^{\alpha} | \nabla^k \partial_t \theta_k |^2 dx \right) = (2 - \beta) \sum_{\kappa=1}^{N} \frac{1}{\delta} e^{\beta \tau} \| \partial_t \theta_k(\tau) \|_{\mathcal{Y}_M^{\kappa}}^2. \quad (198)$$

Remark 18. Just as in [31,65], this damping functional does not play an essential role in our analysis. We only require they have correct sign so that our energy estimates are sufficient. This is guaranteed by the fact that $\beta = 3(\gamma - 1) \leq 3/2$, implied by our range of $\gamma$.

Similarly to [31], we define a truncated-in-time higher order energy function which we use to prove our main theorem.

Definition 6. (Truncated Higher Order Function) Assume $\gamma = 1 + \frac{1}{n}$ for some $n \in \mathbb{Z}_{\geq 2}$, or $\gamma \in (1, 14/13)$. Let $\{ (\partial_t \theta_k, \theta_k) | k = 1, 2, \ldots, N \}$ be the solution to (72)--(74) on $[0, T]$, in the sense of Theorem 2, for some $M \geq 2 \lceil \ast \rceil \alpha + 12$. For $\tau_2 \geq \tau_1$, define the truncated higher order energy function for each $\kappa$, $S^b_k(\tau_1, \tau_2)$, on $[0, T]$ by

$$S^b_k(\tau_1, \tau_2) = S^b(\partial_t \theta_k, \theta_k, \tau_1, \tau_2)$$

$$:= \sup_{\tau_1 \leq \tau' \leq \tau_2} \left( \frac{1}{\delta} e^{\beta \tau'} \| \partial_t \theta_k(\tau') \|_{\mathcal{Y}_M^{\kappa}}^2 + \| \theta_k(\tau') \|_{\mathcal{X}_M^{\kappa}}^2 + \| \theta_k(\tau') \|_{\mathcal{Y}_M^{\kappa}}^2 \right).$$
\[ + \frac{1}{\alpha} \left\| \theta_\kappa (\tau') \right\|_{Y^\alpha (\text{div} \zeta_\kappa)}^2. \]  

(199)

The cumulative truncated energy function is then given by

\[ S_M(\tau_1, \tau_2) = \sum_{\kappa=1}^{N} S_b^\kappa (\tau_1, \tau_2). \]  

(200)

Note that we have the identity

\[ S_M(0, \tau) = S_M(\tau), \]  

(201)

and, for \( \tau_1 \leq \tau_2 \), the inequalities

\[ S_M(\tau_1, \tau_2) \leq S_M(\tau_2) \leq \max[S_M(\tau_1, \tau_2), S_M(\tau_1)] \leq S_M(\tau_1, \tau_2) + S_M(\tau_1). \]  

(202)

With the damping functional from Definition 5, we can state our main energy identity.

**Theorem 6.** (Higher Order Energy Identity) Assume \( \gamma = 1 + \frac{1}{n} \) for some \( n \in \mathbb{Z}_{\geq 2} \), or \( \gamma \in (1, 14/13) \). Let \( \{(\partial_\tau \theta_\kappa, \theta_\kappa)\}_{\kappa=1}^{N} \) be the solution to (72)–(74) on \([0, T]\), in the sense of Theorem 2, for some \( M \geq 2\lceil * \rceil \alpha + 12 \). Suppose the assumptions (117)–(122) hold. Assume that \( \nabla \tilde{W}_\kappa \in X^M_\kappa \) for \( \kappa = 1, 2, \ldots, N \). Then for all \( \tau \in [0, T] \), we have:

\[
\frac{1}{2} \partial_\tau \left( \sum_{\kappa=1}^{N} \left( \frac{1}{\delta} e^{\beta \tau} \| \partial_\tau \theta_\kappa \|_{X^M_\kappa}^2 + \| \theta_\kappa \|_{Y^M_\kappa(\text{div} \zeta_\kappa)}^2 + \frac{1}{\alpha} \| \theta_\kappa \|_{Y^M_\kappa(\text{Curl} \zeta_\kappa)}^2 \right) \right)
+ \frac{1}{2} D(\tau)
\]

\[
= \sum_{\kappa=1}^{N} \left( \sum_{m+|z|=0}^{M} \int_{\Omega} \chi R_\kappa (m, n)^i A^m \phi^m \partial_\kappa i \partial_\kappa j \partial_\kappa j \partial_\kappa j d\chi + \sum_{|k|=0}^{M} \int_{\Omega} \nabla R_\kappa (k)^i \nabla \partial_\kappa i \partial_\kappa j d\chi \right)
\]

\[
- \sum_{\kappa=1}^{N} \sum_{m+|z|=0}^{M} \frac{1}{\delta} e^{\beta \tau} \int_{\Omega} \chi \tilde{W}_\kappa^{\alpha+m} A^m \phi^m \left( \alpha [k]^i \partial_\kappa j \psi_\kappa \right) A^m \phi^m \partial_\kappa \partial_\kappa j \partial_\kappa j d\chi ds
\]

\[
- \sum_{\kappa=1}^{N} \sum_{|z|=0}^{M} \frac{1}{\delta} e^{\beta \tau} \int_{\Omega} \nabla \tilde{W}_\kappa^{\alpha+m} \left( \alpha [k]^i \partial_\kappa j \psi_\kappa \right) \nabla \partial_\kappa i \partial_\kappa j d\chi ds,
\]

(203)

with \( R_\kappa (m, n) \) and \( R_\kappa (k) \) being remainder terms that we can bound effectively.

**Proof.** The proof of Theorem 6 can be adapted from the methods used in [65]. For each fixed \( \kappa \), on \( \text{supp} \chi \) we first divide by \( \tilde{W}_\kappa^\alpha \) in (72), and then act on the result with \( \tilde{W}_\kappa^{\alpha+m} A^m \phi^m \), some \( 0 \leq m + |n| \leq M \), resulting in the identity

\[
\frac{1}{\delta} e^{\beta \tau} \tilde{W}_\kappa^{\alpha+m} A^m \phi^m \left( \partial_\tau \theta_\kappa + \partial_\tau \theta_\kappa \right)
\]
Global Existence for the $N$ Body Euler–Poisson System

\[ + \tilde{W}_k^{\alpha+m} \Lambda^m \beta^m \left( \frac{1}{\tilde{W}_k^{\alpha}} \partial_k \left( \tilde{W}_k^{1+\alpha} \mathcal{A}[k]_n \mathcal{J}_k^{-1/\alpha} \right) \right) \]

\[ + \frac{1}{\delta} e^{\beta \tau} \tilde{W}_k^{\alpha+m} \Lambda^m \beta^m \left( \mathcal{A}[k]_n \partial_k \psi_k \right) = 0. \]

From here, we take the $L^2(\Omega)$ inner product of this equality with $\chi \Lambda^m \beta^m \partial_\tau \theta_k$. We can follow a similar procedure on $\text{supp} \tilde{\chi}$, first acting on (72) with $W_k^{\alpha} \nabla \xi$ and then taking the $L^2(\Omega)$ inner product on the result with $\bar{\chi} \nabla \xi \partial_\tau \theta_k$. From here we can extract the left hand side in (203), and move everything else to the right hand side. Doing this for each $\kappa = 1, 2, \ldots, N$ and then summing gives us the energy identity (203), once we have labelled the remainders of this procedure from the pressure term $\mathcal{R}_k(m, n)$ and $\mathcal{R}_k(k)$ respectively. \hfill \Box

**Theorem 7.** (Higher Order Energy Inequality) Assume $\gamma = 1 + \frac{1}{n}$ for some $n \in \mathbb{Z}_{\geq 2}$, or $\gamma \in (1, 14/13)$. Let $\{\partial_\tau \theta_k, \theta_k\}_{\kappa = 1, 2, \ldots, N}$ be the solution to (72)–(74) on $[0, T]$, in the sense of Theorem 2, for some $M \geq 2 \lceil \gamma * \alpha \rceil + 12$. Suppose the assumptions (117)–(122) hold. Assume that $\nabla \tilde{W}_k \in \mathcal{X}^M_k$ for $\kappa = 1, 2, \ldots, N$. Then for all $[\tau_1, \tau] \subset [0, T]$, we have:

\[ S_M(\tau_1, \tau) \lesssim C_1 S_M(\tau_1) + C_2 (S_M(0) + C_M(0)) + C_3 \sqrt{\delta} + C_4 \sqrt{\delta} S_M(\tau_1, \tau) + \int_{\tau_1}^{\tau} \mathcal{G}(\tau^\prime) S_M(\tau_1, \tau^\prime) \, d\tau^\prime, \quad (204) \]

for some constants $C_1, \ldots, C_5 \in [1, \infty)$, and $\mathcal{G} : [0, \infty) \to [0, \infty)$ integrable.

**Proof.** Let $0 \leq \tau_1 \leq s \leq \tau \leq T$. Integrating the identity (203) over $[\tau_1, s]$, as well as utilising Lemma 2, Theorem 4, and Theorem 5 gives us

\[ \sum_{k=1}^{N} \left( \frac{1}{\delta} e^{\beta \tau_1} \| \partial_\tau \theta_k(s) \|_{\mathcal{X}^M_k}^2 + \| \theta_k(s) \|_{\mathcal{X}^M_k}^2 + \| \theta_k(s) \|_{\mathcal{Y}^M_k(\nabla \xi)}^2 + \frac{1}{\alpha} \| \theta_k(s) \|_{\mathcal{Y}^M_k(\text{div} \xi)}^2 \right) \]

\[ + \int_{\tau_1}^{s} \mathcal{D}(\tau^\prime) \, d\tau^\prime \]

\[ \lesssim \sum_{k=1}^{N} \left( \frac{1}{\delta} e^{\beta \tau_1} \| \partial_\tau \theta_k(\tau_1) \|_{\mathcal{X}^M_k}^2 + \| \theta_k(\tau_1) \|_{\mathcal{Y}^M_k(\nabla \xi)}^2 + \| \theta_k(\tau_1) \|_{\mathcal{Y}^M_k(\text{div} \xi)}^2 \right) \]

\[ + S_M(0) + C_M(0) + \delta S_M(s) \]

\[ + \sum_{k=1}^{N} \left( \sum_{m+|\ell|=0}^{M} \int_{\tau_1}^{s} \int_{\Omega} \chi R_k(m, n) \Lambda^m \beta^m \partial_\tau \theta_k^\ell \, dx \, d\tau^\prime \right) \]

\[ + \sum_{|k|=0}^{M} \int_{\tau_1}^{s} \int_{\Omega} \tilde{\chi} R_k(k) \nabla \xi \partial_\tau \theta_k^\ell \, dx \, d\tau^\prime \]

\[ + \delta^{\alpha - \frac{1}{2}} \int_{\tau_1}^{s} e^{\left( \frac{\theta}{2} - 1 \right) \tau^\prime} \sqrt{S_M(\tau^\prime)} \, d\tau^\prime. \quad (205) \]
For each $\kappa$ most of the terms coming from $R_\kappa (m, n)$ and $R_\kappa (k)$ will be analogous to the ones obtained in [65]. However, just as with the curl estimates in Section 8, we will also have remainder terms that look, for example, like a weighted $L^2(\Omega)$ inner product of $A^m \beta^2 \mu_\kappa$ and $A^m \beta^2 \partial_t \theta_\kappa$, coming from the derivatives of $A[\kappa]$ and $f_\kappa^{-1/2}$. These terms can be bounded, for example like

$$
\left| \int_\Omega \chi \tilde{W}_\kappa^{\alpha + m} A^m \beta^2 \mu_\kappa \Lambda^m \beta^2 \partial_t \theta_\kappa \, dx \right| \lesssim \sqrt{\delta} e^{-\frac{\beta}{2} \tau} \sqrt{S_M(\tau)},
$$

(206)

where we use (117) to bound $\|\nabla \mu_\kappa \|_{X^\ell}$ by a constant.

Moreover, as we are assuming $\delta$ is small, in particular $\delta < 1$, we have the bound $\delta + \delta^{\alpha - \frac{1}{2}} < 2\sqrt{\delta}$, as $\alpha \geq 2$. Thus we have

$$
\sum_{\kappa = 1}^N \left( \frac{1}{\delta} e^{\delta s} \|\partial_t \theta_\kappa(s)\|_{X^\ell}^2 + \|\theta_\kappa(s)\|_{X^\ell}^2 + \|\theta_\kappa(s)\|_{Y_M(\nabla \theta_\kappa)} + \frac{1}{\alpha} \|\theta_\kappa(s)\|_{Y_M(\nabla \theta_\kappa)} \right)
\lesssim S_M(\tau_1) + S_M(0) + C_M(0) + \sqrt{\delta} S_M(s)
+ \sqrt{\delta} \int_{\tau_1}^s e^{\left(\frac{\beta}{2} - 1\right) \tau'} \sqrt{S_M(\tau')} \, d\tau' + \sqrt{\delta} \int_{\tau_1}^s e^{-\frac{\beta}{2} \tau'} \left(\sqrt{S_M(\tau')} + S_M(\tau')\right) \, d\tau'
\lesssim S_M(\tau_1) + S_M(0) + C_M(0) + \sqrt{\delta} S_M(s)
+ \sqrt{\delta} + \sqrt{\delta} \int_{\tau_1}^s \left(e^{\left(\frac{\beta}{2} - 1\right) \tau'} + e^{-\frac{\beta}{2} \tau'}\right) S_M(\tau') \, d\tau'
\lesssim S_M(\tau_1) + S_M(0) + C_M(0) + \sqrt{\delta} S_M(\tau_1, s)
+ \sqrt{\delta} + \sqrt{\delta} \int_{\tau_1}^s \left(e^{\left(\frac{\beta}{2} - 1\right) \tau'} + e^{-\frac{\beta}{2} \tau'}\right) S_M(\tau_1, \tau') \, d\tau'.
$$

(207)

The second bound is obtained by using Young’s inequality which gives us $\sqrt{\delta} \sqrt{S_M(\tau')}$
\lesssim \sqrt{\delta} + \sqrt{\delta} S_M(\tau')$, and also the fact that $e^{\left(\frac{\beta}{2} - 1\right) \tau}$ and $e^{-\frac{\beta}{2} \tau}$ are integrable, as $0 < \beta \leq 3/2$. The last bound is obtain by using (202), as well as the integrability of $e^{\left(\frac{\beta}{2} - 1\right) \tau}$ and $e^{-\frac{\beta}{2} \tau}$ once again.

As (207) holds for all $s \in [\tau_1, \tau]$, we can take the supremum over this interval, and obtain

$$
S_M(\tau_1, \tau) \leq C_1 S_M(\tau_1) + C_2 \left( S_M(0) + C_M(0) \right) + C_3 \sqrt{\delta}
+ C_4 \sqrt{\delta} S_M(\tau_1, \tau) + C_5 \sqrt{\delta} \int_{\tau_1}^\tau G(\tau') S_M(\tau_1, \tau') \, d\tau',
$$

(208)

where $G(\tau) = e^{\left(\frac{\beta}{2} - 1\right) \tau} + e^{-\frac{\beta}{2} \tau}$. The statement (204) follows by noting that we can adjust constants on the right hand side of (207) to be $\geq 1$ if necessary. \qed
10. Proof of Theorem 3.

Let $T$ be such that
\[
\sup_{0 \leq \tau \leq T} S_M(\tau) = S_M(T) \leq \tilde{C} (S_M(0) + C_M(0) + \sqrt{\delta}), \quad (209)
\]
for some constant $\tilde{C}$, whose existence is guaranteed by the Local Well-Posedness theory set out in Theorem 2. Let $C^*$ be defined by
\[
C^* = 3(C_1\tilde{C} + C_2 + C_3), \quad (210)
\]
with $C_i, i = 1, 2, 3, 4, 5$ given in Theorem 7. Note that $\tilde{C} < C^*$, so given
\[
T^* = \sup \{ \tau \mid \text{Solution to (72) -- (74) exists on } [0, \tau], S_M(\tau) \leq C^*(S_M(0) + C_M(0) + \sqrt{\delta}) \}, \quad (211)
\]
we have $T \leq T^*$. Now letting $\tau_1 = T/2$, Theorem 7 tells us that for any $\tau \in [*T_2, T^*]$, we have
\[
S_M\left(\frac{T}{2}, \tau\right) \leq C_1 S_M\left(\frac{T}{2}\right) + C_2 \sqrt{\delta} + C_3 (C_M(0) + S_M(0)) + C_4 \sqrt{\delta}S_M\left(\frac{T}{2}, \tau\right) + C_5 \sqrt{\delta} \int_{\frac{T}{2}}^{\tau} G(\tau') S_M\left(\frac{T}{2}, \tau'\right) d\tau'. \quad (212)
\]
Let $\delta$ satisfy
\[
\delta \leq \min \left(\left(4C_4\right)^{-2}, \left(4C_5 \int_{0}^{\infty} G(\tau') d\tau'\right)^{-2}\right). \quad (213)
\]
Then we have
\[
S_M\left(\frac{T}{2}, \tau\right) \leq 2C_1 S_M\left(\frac{T}{2}\right) + 2C_2 \sqrt{\delta} + 2C_3 (C_M(0) + S_M(0)). \quad (214)
\]
Using (209) to bound $S_M(T/2)$ by $\tilde{C} \left( C_M(0) + S_M(0) + \sqrt{\delta} \right)$, we obtain
\[
S_M\left(\frac{T}{2}, \tau\right) \leq 2C_1 \tilde{C} \left( C_M(0) + S_M(0) + \sqrt{\delta} \right) + 2C_2 \sqrt{\delta} + 2C_3 (C_M(0) + S_M(0)) \leq 2(C_1\tilde{C} + C_2 + C_3) \left( C_M(0) + S_M(0) + \sqrt{\delta} \right) < C^* \left( C_M(0) + S_M(0) + \sqrt{\delta} \right). \quad (215)
\]
Combining (215) with (209), and using (202) we obtain

\[ S_M(\tau) \leq \max\{\bar{C}, 2(C_1 \bar{C} + C_2 + C_3)\} \left( C_M(0) + S_M(0) + \sqrt{\delta} \right) \]

\[ < C^* \left( C_M(0) + S_M(0) + \sqrt{\delta} \right) \]  

(216)

for all \( \tau \in [0, T^*). \) Shrinking \( \delta \) further if necessary, we also improve our a priori assumptions (119)–(122). For example, for all \( \tau \in [0, T^*) \),

\[ \|\mathcal{A}[\kappa] - II\|_{L^\infty} = \left\| \int_0^\tau \partial_\tau \mathcal{A}[\kappa] d\tau' \right\|_{L^\infty} \leq C \sqrt{\delta} \int_0^\tau e^{-\frac{\beta}{2} \tau'} S_M(\tau') d\tau' < \varepsilon_2 \]

(217)

for small enough \( \delta \). Similarly for \( J_k \), and \( \theta_\kappa \). Then, by continuity of \( S_M(\tau) \) as a function of \( \tau \), we must have that \( T^* = \infty \). Therefore, the bound (115) follows. It is left to prove (116). Fix \( \kappa \in \{1, 2, \ldots, N\} \). Let \( \tau_1 > \tau_2 \). For any \( m + |n| \leq M \), we have the estimate

\[ \int_\Omega \chi \tilde{W}_k^{\alpha + m} |\Lambda^m \bar{J}^n_\kappa (\theta_\kappa(\tau_1) - \theta_\kappa(\tau_2))|^2 \, dx \]

\[ = \int_\Omega \chi \tilde{W}_k^{\alpha + m} \left| \int_{\tau_2}^{\tau_1} \Lambda^m \bar{J}^n_\kappa \partial_\tau \theta_\kappa(\tau') d\tau' \right|^2 \, dx \]

\[ \lesssim \left( \int_{\tau_2}^{\tau_1} e^{-\frac{\beta}{2} \tau'} d\tau' \right) \left( \int_{\tau_2}^{\tau_1} e^{\frac{\beta}{2} \tau'} \int_\Omega \chi \tilde{W}_k^{\alpha + m} |\Lambda^m \bar{J}^n_\kappa \partial_\tau \theta_\kappa|^2 \, dx \, d\tau' \right) \]

\[ \lesssim \delta S_M(\tau_1) \int_{\tau_2}^{\tau_1} e^{-\frac{\beta}{2} \tau'} d\tau' \]

\[ \lesssim \delta \left( e^{-\frac{\alpha_1}{2} \tau_2} - e^{-\frac{\alpha_1}{2} \tau_1} \right) \rightarrow 0 \quad \tau_1, \tau_2 \rightarrow \infty \]

(218)

The bound follows from Cauchy-Schwarz in \( \tau \) and the global energy estimate (115). A similar bound holds for any \( |k| \leq N \) on \( \tilde{I}_\kappa \). Thus \( \theta_\kappa(\tau_n) \) is Cauchy for any strictly increasing sequence \( \tau_n \). As \( \mathcal{X}_k^M \) is a Banach space, \( \lim_{\tau \to \infty} \theta_\kappa(\tau) \) exists in \( \mathcal{X}_k^M \); we call this limit \( \theta_\kappa(\infty) \). This gives (116).

Appendix A: Local Well-Posedness

The local-in-time theory for the system (72)–(74) can be adapted from [32], using the framework set out in [41]. The tidal terms of the form $\mathcal{J}_{[\kappa,\kappa]}$, defined in (63), are present because $N \geq 2$, since these terms are exactly the ones which encode how the stars in our system interact with each other via gravity. In [32], $N = 1$, meaning they only have to deal with the self-interaction terms $\mathcal{J}_{\kappa}$, also defined in (63). As mentioned in the introduction, in Eulerian coordinates, the gravitational potential term $\rho_\kappa \nabla \phi$ in (7) is lower order, from the point of view of derivatives, to $\nabla P_\kappa$. As discussed in [32], this means that it is enough to show sufficient a priori estimates for the gravitational potential terms in order to construct a local-in-time theory. For the tidal terms $\mathcal{J}_{[\kappa,\kappa]}$, these can be shown using similar methods to Proposition 1. For details on the self-interaction terms and other aspects of constructing the local-in-time theory, see [32,41].

Appendix B: Lower Order Estimates

In this appendix we state some estimates that will be used in the proof of global-in-time existence of our solutions.

Lemma 2. Assume $\gamma = 1 + \frac{1}{n}$ for some $n \in \mathbb{Z}_{\geq 2}$, or $\gamma \in (1, 14/13)$. Let $((\partial_\tau \theta_\kappa, \theta_\kappa)|\kappa = 1, 2, \ldots, N)$ be the solution to (72)–(74) on $[0, T]$, in the sense of Theorem 2, for some $M \geq 2^\Gamma \alpha + 12$. Suppose the assumptions (117)–(122) hold. Then for all $\tau \in [0, T]$, we have:

$$\sum_{\kappa = 1}^{N} \|\theta_\kappa\|_{H^M(\tau)}^2 \lesssim \delta S_M(\tau). \quad (219)$$

Proof. The proof is readily adapted from [65]. It is an application of the Fundamental Theorem of Calculus.

Lemma 3. Assume $\gamma = 1 + \frac{1}{n}$ for some $n \in \mathbb{Z}_{\geq 2}$, or $\gamma \in (1, 14/13)$. Let $((\partial_\tau \theta_\kappa, \theta_\kappa)|\kappa = 1, 2, \ldots, N)$ be the solution to (72)–(74) on $[0, T]$, in the sense of Theorem 2, for some $M \geq 2^\Gamma \alpha + 12$. Suppose the assumptions (117)–(118) hold. Assume that $\nabla \hat{W}_\kappa \in X^M_\kappa$ for $\kappa = 1, 2, \ldots, N$. Let $(m, n, k) \in \mathbb{Z}_{\geq 0} \times \mathbb{Z}_3^2 \times \mathbb{Z}_3^3$ be such that $1 \leq \max \{m + |n|, |k|\} \leq M$. Then for each $\kappa \in \{1, \ldots, N\}$ and all $\tau \in [0, T]$, we have:

$$\int_{\Omega} \hat{W}_\kappa^{1+\alpha+m} \left| A^m \partial_\Omega (\mathcal{J}_{[\kappa,\kappa]}) \right|^2 dx + \int_{\Omega} \left| \nabla \hat{W}_\kappa^{1+\alpha} \left( \mathcal{J}_{\kappa}^{-1} \right) \right|^2 dx \lesssim \|\nabla \mu_\kappa\|_{H^M(\tau)}^2 + S_M(\tau). \quad (220)$$

If instead we have $1 \leq \max \{m + |n|, |k|\} \leq M/2$, then for each $\kappa \in \{1, \ldots, N\}$ and all $\tau \in [0, T]$, we have:

$$\left\| \hat{W}_\kappa^{m} A^m \partial_\Omega [\kappa] \right\|_{L^\infty(\Omega)}^2 + \left\| \hat{W}_\kappa^{m} A^m \partial_\Omega \left( \mathcal{J}_{\kappa}^{-1} \right) \right\|_{L^\infty(\Omega)}^2 \lesssim \|\nabla \mu_\kappa\|_{H^M(\tau)}^2 + S_M(\tau). \quad (221)$$
Proof. The full proof of (220) can be adapted very easily from [65]. The main technical difficulties are for the integrals localised near the boundary, on supp $\chi$, with regards to ensuring each term resulting from the application of the Leibniz rule to either $\Lambda^m \partial^\alpha (\mathcal{A}[\kappa])$ or $\Lambda^m \partial^\alpha (\mathcal{J}_\kappa^{-1})$ appears with a high enough power of $\tilde{W}_\kappa$ to be bounded in either the $\mathcal{X}_M^\kappa$ or $\mathcal{Y}_M^\kappa (\nabla \zeta)$ norms.

For the $L^\infty$ estimates in (221), we first concentrate on the $\mathcal{A}[\kappa]$ term. Note that (56) gives

$$\partial \mathcal{A}[\kappa]_i = -\mathcal{A}[\kappa]_j \mathcal{A}[\kappa]_s \partial s \zeta_j,$$

and similarly for $\Lambda \mathcal{A}[\kappa]$. We apply (222) repeatedly to obtain

$$\left\| \tilde{W}_\kappa^m \Lambda^m \partial^\alpha \mathcal{A}[\kappa] \right\|_{L^\infty(\Omega)} \lesssim \sum_{a+b=1} \left\| \mathcal{A}[\kappa] \right\|_{L^\infty(\Omega)} \prod_{\nu+\lambda=1} \left\| \tilde{W}_\kappa^\nu \Lambda^\nu \partial^\lambda (\nabla \zeta) \right\|_{L^\infty(\Omega)}$$

where $l_a + l_b, l_{ij} + l_{ij}$ are nonnegative integers. By (120), we have $\|\mathcal{A}[\kappa]\|_{L^\infty(\Omega)} \lesssim 1$. It is left to bound terms of the form $\left\| \tilde{W}_\kappa^\nu \Lambda^\nu \partial^\lambda (\nabla \zeta) \right\|_{L^\infty(\Omega)}$ for any $\nu \in \mathbb{Z}_{\geq 0}, \lambda \in \mathbb{Z}_{\geq 0}^3$ such that $1 \leq \nu + |\lambda| \leq m + |\kappa|$. First we have

$$\left\| \tilde{W}_\kappa^\nu \Lambda^\nu \partial^\lambda (\nabla \zeta) \right\|_{L^\infty(\Omega)} \lesssim \left\| \tilde{W}_\kappa^\nu \Lambda^\nu \partial^\lambda (\nabla \theta) \right\|_{L^\infty(\Omega)} + \left\| \tilde{W}_\kappa^\nu \Lambda^\nu \partial^\lambda (\nabla \mu) \right\|_{L^\infty(\Omega)}.$$  

For the $\theta$ term, we write $\nabla \Lambda^\nu \partial^\lambda \nabla$ as a linear combination of operators of the form $\nabla \Lambda^\nu \partial^\lambda \nabla \theta$, $\nu' + |\lambda'| \leq \nu + |\lambda|$ with smooth coefficients using (88), (89), and (90). Finally, employing (232) and (231) from Lemma 8 to the $\theta$ and $\mu$ terms respectively gives us

$$\left\| \tilde{W}_\kappa^\nu \Lambda^\nu \partial^\lambda (\nabla \zeta) \right\|_{L^\infty(\Omega)} \lesssim \sum_{\nu' + |\lambda'| \leq \nu + |\lambda|} \left\| \tilde{W}_\kappa^\nu \nabla \Lambda^\nu \partial^\lambda (\nabla \theta) \right\|_{L^\infty(\Omega)} + \left\| \tilde{W}_\kappa^\nu \Lambda^\nu \partial^\lambda (\nabla \mu) \right\|_{L^\infty(\Omega)} \lesssim \|\nabla \mu\|_{\mathcal{X}_M^\kappa} + \sqrt{S_M(\tau)}.$$  

The proof of the same bound for the $\mathcal{J}_\kappa$ term is similar, where we utilise the differentiation formula (57) instead.

Appendix C: Commutators and Transformations of Derivatives

We recall that in Section 4.2, we introduced our angular and radial derivatives, $\partial$ and $\Lambda$ and the various commutator identities (93)–(96). In this appendix, we state how these commutators can be written as radial and angular derivatives, following [31]. We also record how $\Lambda^m \partial^\alpha$ can be written as a sum of $\nabla^k$ on an appropriate sub-domain of the unit ball $B_1$, and vice versa.
Lemma 4. (Higher order commutator identities) Let $\partial_s$ be a rectangular derivative. Then for $n \in \mathbb{Z}_\geq 0$ with $|n| > 0$, we have

$$\left[ A^m \beta^n, \partial_s \right] = \sum_{i=1}^{m+|n|} \sum_{\begin{array}{c} a + |b| = i \\ a \leq m+1 \end{array}} \mathcal{K}_{s,i,a,b} A^a \beta^b,$$  

where $\mathcal{K}_{s,i,a,b}$ are smooth functions away from the origin. If $|n| = 0$, then we instead have

$$\left[ A^m, \partial_s \right] = \sum_{i=1}^{m+|n|} \sum_{\begin{array}{c} a + |b| = i \\ a \leq m \end{array}} \mathcal{F}_{s,i,a,b} A^a \beta^b,$$  

where, again, $\mathcal{F}_{s,i,a,b}$ are smooth functions away from the origin.

Lemma 5. Let $B_1$ be the closed unit ball in $\mathbb{R}^3$, and let $A^m \beta^n$ and $\nabla^k$ be defined as in (91) and (92). Then we have

$$A^m \beta^n = \sum_{|k|=0}^{m+|n|} Q_k \nabla^k,$$  

for some $Q_k$, smooth on $B_1$.

There is also a partial converse to Lemma 5.

Lemma 6. Let $B_1$ be the closed unit ball in $\mathbb{R}^3$, and let $A^m \beta^n$ and $\nabla^k$ be defined as in (91) and (92). Then we have

$$\nabla^k = \sum_{m+|n|=0}^{|k|} Z_{(m,n)} A^m \beta^n,$$  

for some functions $Z_{(m,n)}$, smooth on any region removed from the origin in $B_1$.

The proofs of all three lemmas in this appendix can be found in [65], for example.

Appendix D: Hardy-Type Inequality and Hardy–Sobolev Embeddings

One of the main tools we use is a higher order Hardy-type embedding which tells us that a weighted Sobolev space on a domain can be realised in a Sobolev space of lower regularity, in essence sacrificing regularity to remove degeneracy near the boundary.

Definition 7. For a bounded domain $\Omega \subset \mathbb{R}^3$, and $s \in \mathbb{Z}_{\geq 0}$, define the Sobolev space $H^s(\Omega)$ by

$$H^s(\Omega) = \left\{ F \in L^2(\Omega) : \nabla^k F \text{ is weakly in } L^2(\Omega), \text{ for } k \in \mathbb{Z}_{\geq 0}, 0 \leq |k| \leq b \right\},$$

with norm given by

$$\| F \|_{H^s(\Omega)}^2 = \sum_{|k|=0}^{b} \int_{\Omega} |\nabla^k F|^2 \, dx.$$  

The definition of $H^s(\Omega)$ can be extended to $s \in \mathbb{R}_{\geq 0}$ by interpolation.
**Definition 8.** For a bounded domain $\mathcal{O} \subset \mathbb{R}^3$, $\alpha > 0$ and $b \in \mathbb{Z}_{\geq 0}$, define the weighted Sobolev space $H^{\alpha,b}(\mathcal{O})$ by

$$H^{\alpha,b}(\mathcal{O}) = \left\{ d^\frac{\alpha}{2} F \in L^2(\mathcal{O}) : \nabla^k F \text{ is weakly in } L^2(\mathcal{O}, d^\alpha dx), \right.$$  

$$k \in \mathbb{Z}_{\geq 0}^3, \ 0 \leq |k| \leq b \right\},$$

with norm given by

$$\| F \|^2_{H^{\alpha,b}(\mathcal{O})} = \sum_{|k|=0}^b \int_{\mathcal{O}} d^\alpha |\nabla^k F|^2 \, dx,$$

where $d = d(x, \partial \mathcal{O})$ is the distance function to the boundary on $\mathcal{O}$.

Given these definitions, we have the following embedding.

**Lemma 7.** Let $\mathcal{O}$ be as above and let $b \in \mathbb{Z}_{>0}$ and $0 < \alpha \leq 2b$. Then the Banach space $H^{\alpha,b}(\mathcal{O})$ embeds continuously into $H^{b-\frac{\alpha}{2}}(\mathcal{O})$.

The proof of Lemma 7 is standard and can be found in [45].

Finally, we state the Hardy–Sobolev bounds for $L^\infty$-norm in terms of our energy norms. Recall the spaces $\chi^b_\kappa$ and $\bar{\chi}^b_\kappa(\nabla \zeta_\kappa)$ with their associated norm and semi-norm respectively, given in Definition 2. We also recall the definitions of $\chi$ and $\bar{\chi}$ given in (100) and (101).

**Lemma 8.** Let $a \in \mathbb{Z}_{\geq 0}$ and $b \in \mathbb{Z}_3^\geq 0$, and let $a + |b| = j$. Then for each $\kappa \in \{1, 2, \ldots, N\}$,

$$\left\| \Lambda^a \partial^b \tilde{\chi} \right\|_{L^\infty(\Omega)} \lesssim \| F \|_{X^{[\ast]a+2j+4}_\kappa},$$

(230)

$$\left\| \bar{\Lambda}^a \partial^b \tilde{\chi} \right\|_{L^\infty(\Omega)} \lesssim \| F \|_{X^{[\ast]a+j+6}_\kappa},$$

(231)

$$\left\| \bar{\Lambda}^a \nabla \partial^b \tilde{\chi} \right\|_{L^\infty(\Omega)} \lesssim \| F \|_{Y^{[\ast]a+j+6}_\kappa(\nabla \zeta_\kappa)},$$

(232)

**Proof.** Fix $\kappa \in \{1, 2, \ldots, N\}$. We begin with (230). First, using Lemma 5 and the Sobolev embedding $H^2 \hookrightarrow L^\infty$, we have

$$\left\| \Lambda^a \partial^b \tilde{\chi} \right\|_{L^\infty(\Omega)} \lesssim \| F \|_{H^{2+j}(\Omega)}.$$  

(233)

Then, we use Lemma 7 to obtain

$$\| F \|_{H^{2+j}(\Omega)} \lesssim \| F \|_{H^{[\ast]a+[\ast]a+2j+4, [\ast]a+2j+4}(\Omega)}$$  

(234)

having noted that

$$2 + j \leq [\ast]a + 2j + 4 - \left( \alpha + [\ast]a + 2j + 4 - \frac{\alpha + [\ast]a + 2j + 4}{2} \right).$$

Using (71), we have

$$\| F \|^2_{H^{[\ast]a+[\ast]a+2j+4, [\ast]a+2j+4}(\Omega)} = \sum_{|k|=0} \int_{\Omega} d^{a+[\ast]a+2j+4} \| \nabla^k F \|^2 \, dx.$$
where \( d_\Omega(x) = d(x, \partial \Omega) \), and \( \tilde{W}_k \) is given in (70). Using \( \chi + \tilde{\chi} = 1 \), and Lemma 6, we have

\[
\sum_{|k|=0}^{[\ast] \alpha + 2j + 4} \int_{\Omega} \tilde{W}_k^{\ast \alpha + [\ast] \alpha + 2j + 4} \var{\nabla F}^2 \, dx
\]

\[
\leq \int_{\Omega} \tilde{W}_k^{\ast \alpha + [\ast] \alpha + 2j + 4} \left( \sum_{m+|l|=0}^{[\ast] \alpha + 2j + 4} \chi |A^m \beta^l F|^2 + \sum_{|k|=0}^{[\ast] \alpha + 2j + 4} \tilde{\chi} \var{\nabla F}^2 \right) \, dx
\]

\[
\leq \sum_{m+|l|=0}^{[\ast] \alpha + 2j + 4} \int_{\Omega} \chi \tilde{W}_k^{\ast \alpha + m} |A^m \beta^l F|^2 \, dx + \sum_{|k|=0}^{[\ast] \alpha + 2j + 4} \int_{\Omega} \tilde{\chi} \tilde{W}_k^{\ast \alpha} \var{\nabla F}^2 \, dx
\]

\[
= \| F \|_{2 \chi^{[\ast] \alpha + 2j + 4}}^2 ,
\]

where the second bound is because \( \tilde{W}_k \) is bounded on \( \Omega \), and the last line is by definition. Bounds (233)–(236) give (230).

For (231) we first have

\[
\left\| \tilde{W}_k^a A^a \beta^b F \right\|_{L^\infty(\Omega)} \lesssim \left\| \tilde{W}_k^a A^a \beta^b F \right\|_{L^\infty(\supp \chi)} + \left\| \tilde{W}_k^a A^a \beta^b F \right\|_{L^\infty(\supp \tilde{\chi})} .
\]

The estimate

\[
\left\| \tilde{W}_k^a A^a \beta^b F \right\|_{L^\infty(\supp \chi)} \lesssim \| F \|_{\chi^{[\ast] \alpha + j + 6}}
\]

is standard and can be found in [37,45]. For the estimate on \( \supp \tilde{\chi} \), we have

\[
\left\| \tilde{W}_k^a A^a \beta^b F \right\|_{L^\infty(\supp \tilde{\chi})} \lesssim \| F \|_{H^{2j}(\supp \tilde{\chi})}
\]

by first bounding \( \tilde{W}_k^a \) in \( L^\infty \), and then using Lemma 5 and the \( H^2 \hookrightarrow L^\infty \) embedding. Then we have

\[
\| F \|_{H^{2j}(\supp \tilde{\chi})}^2 = \sum_{|k|=0}^{2+j} \int_{\supp \tilde{\chi} \cap \supp \chi} \chi \var{\nabla F}^2 \, dx + \sum_{|k|=0}^{2+j} \int_{\supp \tilde{\chi}} \tilde{\chi} \var{\nabla F}^2 \, dx.
\]

On both \( \supp \chi \) and \( \supp \tilde{\chi} \cap \supp \chi \), \( \tilde{W}_k \sim 1 \). Moreover, since \( \supp \tilde{\chi} \cap \supp \chi \) is removed from the origin, we can apply Lemma 6. Therefore, we have the bound

\[
\| F \|_{H^{2j}(\supp \tilde{\chi})}^2 \lesssim \sum_{m+|l|=0}^{2+j} \int_{\supp \tilde{\chi} \cap \supp \chi} \chi \tilde{W}_k^{\ast \alpha + m} |A^m \beta^l F|^2 \, dx
\]

\[
+ \sum_{|k|=0}^{2+j} \int_{\supp \tilde{\chi}} \tilde{\chi} \tilde{W}_k^{\ast \alpha} \var{\nabla F}^2 \, dx
\]
\[
\|F\|^2_{X^2_{\kappa}} \lesssim \|F\|^2_{X^{\ast \kappa}_{\kappa}} \|\alpha + j + 6\|.
\]

(241)

Bounds (237)–(241) give (231). The proof for (232) requires similar estimates as for (231) on \(\text{supp} \chi\) and \(\text{supp} \bar{\chi}\). The \(\text{supp} \chi\) bound can be found in [37,45] for (231), and the bound for \(\text{supp} \bar{\chi}\) follows the same strategy as (239)–(241), requiring the additional fact that \(J_\kappa \sim 1\) on \(\Omega\) due to (121). This completes the proof of the lemma.
