ON WEYL CALCULUS IN INFINITELY MANY VARIABLES

INGRID BELTITĂ AND DANIEL BELTITĂ

Abstract. We outline an abstract approach to the pseudo-differential Weyl calculus for operators in function spaces in infinitely many variables. Our earlier approach to the Weyl calculus for Lie group representations is extended to the case of representations associated with infinite-dimensional coadjoint orbits. We illustrate the approach by the case of infinite-dimensional Heisenberg groups. The classical Weyl-Hörmander calculus is recovered for the Schrödinger representations of the finite-dimensional Heisenberg groups.

1. Introduction

The pseudo-differential Weyl calculus which takes into account a magnetic field on $\mathbb{R}^n$ was recently developed in a series of papers including [MP04], [IMP07], [MP10], and [IMP10]. We have shown ([BB09a], [BB09b], [BB10a], [BB10c]) that a representation theoretic approach to that calculus can lead to a number of improvements such as an extension to the situation of magnetic fields on any nilpotent Lie group instead of the abelian group $(\mathbb{R}^n, +)$ and, more importantly, establishing the relationship to the Weyl quantization discussed for instance in [Ca07]. The latter point was settled by recovering the magnetic calculus as the Weyl quantization for a finite-dimensional coadjoint orbit of a Lie group which is in general infinite-dimensional.

In the present paper we wish to point out that this representation theoretic approach can also be applied in the case of certain infinite-dimensional coadjoint orbits. As a by-product of this method, we provide a generalized version for the pseudo-differential calculus developed in [AD96] and [AD98] for the differential operators of infinite-dimensional analysis (see e.g., [Ku875], [Br86], [DF91], or [Bh98]).

2. An abstract framework for the Weyl calculus

In this section we develop a version of the localized Weyl calculus of [BB09a] and [BB10a], which is general enough for dealing with Weyl quantizations of some infinite-dimensional coadjoint orbits.

Setting 2.1. Let $M$ be a locally convex Lie group with Lie algebra $L(M) = m$ and smooth exponential map $\exp_M : m \to M$ (see [Ne06]), and $\pi : M \to \mathcal{B}(\mathcal{H})$ a continuous unitary representation on the complex Hilbert space $\mathcal{H}$. We shall think of the dual space $m^*$ as a locally convex space with respect to the weak*-topology. Let $\mathcal{UC}_b(m^*)$ be the commutative unital $C^*$-algebra of uniformly continuous bounded functions on the locally convex space $m^*$ and for every $\mu \in \mathcal{UC}_b(m^*)^*$ define the function

$$\hat{\mu} : m \to \mathbb{C}, \quad \hat{\mu}(X) = \langle \mu, e^{i\langle \cdot, X \rangle} \rangle,$$

Key words and phrases. Weyl calculus; infinite-dimensional Heisenberg group; coadjoint orbit.
where either of the duality pairings \( m^* \times m \to \mathbb{R} \) and \( UC_b(m^*)^* \times UC_b(m^*) \to \mathbb{C} \) is denoted by \( \langle \cdot, \cdot \rangle \). Assume the setting defined by the following data:

- a locally convex real vector space \( \Xi \) and a Borel measurable map \( \theta : \Xi \to m \),
- a locally convex space \( \Gamma \hookrightarrow UC_b(m^*)^* \) with continuous inclusion map, where \( UC_b(m^*)^* \) is endowed with the weak*-topology,
- a locally convex space \( \mathcal{Y}_{\Xi,\infty} \hookrightarrow \mathcal{Y} \) with continuous inclusion map, subject to the following conditions:

1. The linear mapping
   \[ \mathcal{F}_\Xi : \Gamma \to UC_b(\Xi), \quad \mu \mapsto \hat{\mu} \circ \theta \]
   is well defined and injective. Let us denote \( Q_\Xi := \mathcal{F}_\Xi(\Gamma) \hookrightarrow UC_b(\Xi) \) and endow it with the topology which makes the Fourier transform
   \[ \mathcal{F}_\Xi : \Gamma \to Q_\Xi \]
   into a linear topological isomorphism. Note that there also exists the linear topological isomorphism \((\mathcal{F}_\Xi^*)^{-1} : \Gamma^* \to Q_\Xi^*\).

2. We have the well-defined continuous sesquilinear functional
   \[ \mathcal{Y}_{\Xi,\infty} \times \mathcal{Y}_{\Xi,\infty} \to Q_\Xi, \quad (\phi, \psi) \mapsto \langle \pi(\exp_M(\theta(\cdot)))\phi | \psi \rangle. \]

**Definition 2.2.** In this framework, the quasi-localized Weyl calculus for \( \pi \) along \( \theta \) is the linear map \( Op : \Gamma^* \to \mathcal{L}(\mathcal{Y}_{\Xi,\infty}, \mathcal{Y}_{\Xi,\infty}) \) defined by

\[
(\text{Op}(a)\phi | \psi) = \langle (\mathcal{F}_\Xi^*)^{-1}(a), \pi(\exp_M(\theta(\cdot)))\phi | \psi \rangle
\]

for \( a \in \Gamma^* \) and \( \phi, \psi \in \mathcal{Y}_{\Xi,\infty} \), where \( \mathcal{Y}_{\Xi,\infty} \) denotes the space of antilinear continuous functionals on \( \mathcal{Y}_{\Xi,\infty} \).

**Remark 2.3.** In the setting of Definition 2.2 let us assume that the linear functional \((\mathcal{F}_\Xi^*)^{-1}(a) \in Q_\Xi^* \) is defined by a complex Borel measure on \( \Xi \) denoted in the same way. For arbitrary \( \phi, \psi \in \mathcal{Y}_{\Xi,\infty} \), the function \( \langle \pi(\exp_M(\theta(\cdot)))\phi | \psi \rangle \) is uniformly bounded on \( \Xi \), hence it is integrable with respect to the measure \((\mathcal{F}_\Xi^*)^{-1}(a) \) and equation (2.1) takes the form

\[
(\text{Op}(a)\phi | \psi) = \int_{\Xi} \langle \pi(\exp_M(\theta(\cdot)))\phi | \psi \rangle d(\mathcal{F}_\Xi^*)^{-1}(a)
\]

which is very similar to the definition of the Weyl-Pedersen calculus for irreducible representations of finite-dimensional nilpotent Lie groups with the locally convex space \( \Xi \) in the role of a predual of the coadjoint orbit under consideration (see for instance \[BB09\] and \[BB10\]).

Moreover, for arbitrary \( \phi, \psi \in \mathcal{Y} \) we have \( \| \langle \pi(\exp_M(\theta(\cdot)))\phi | \psi \rangle \|_{\infty} \leq \| \phi \| \cdot \| \psi \| \), hence by (2.2) we get \( \| \text{Op}(a)\phi | \psi \| \leq \| (\mathcal{F}_\Xi^*)^{-1}(a) \| \| \phi \| \cdot \| \psi \| \). Thus \( \| \text{Op}(a) \| \leq \| (\mathcal{F}_\Xi^*)^{-1}(a) \| \). Here \( \| (\mathcal{F}_\Xi^*)^{-1}(a) \| \) denotes the norm of the measure \((\mathcal{F}_\Xi^*)^{-1}(a) \) viewed as an element of the dual Banach space \( UC_b(\Xi)^* \).

**Remark 2.4.** Assume the setting of Definition 2.2 again. We note that, due to the continuous inclusion map \( \Gamma \hookrightarrow UC_b(m^*)^* \), every function \( f \in UC_b(m^*) \) gives rise to a functional \( a_f \in \Gamma^* \), \( a_f(\gamma) = \langle \gamma, f \rangle \) for every \( \gamma \in \Gamma \).

Furthermore, let us assume that the function \( f \in UC_b(m^*) \) is the Fourier transform of a Radon measure \( \mu \in \mathcal{M}_1(\Xi) \), in the sense that \( f(\cdot) = \int_{\Xi} e^{i\langle \cdot, \theta(X) \rangle} d\mu(X) \).
Then it is straightforward to check that $F_{\Xi}(\mu) = a_f$, hence one can use Remark 2.3 to see that $\text{Op}(a_f) = \int_\Xi \pi(\exp_M(\theta(\cdot))) d\mu$ and $\text{Op}(a_f) \in B(Y)$.

**Preduals for coadjoint orbits.** The following notion recovers the magnetic pre-duals of [BB09a] as very special cases.

**Definition 2.5.** Let $g$ be a nilpotent locally convex Lie algebra and pick any coadjoint orbit $O \subseteq g^*$ of the corresponding Lie group $G = (g, \ast)$ defined by the Baker-Campbell-Hausdorff multiplication $\ast$. A predual for $O$ is any pair $(\Xi, \theta)$, where $\Xi$ is a locally convex real vector space and $\theta: \Xi \to g$ is a continuous linear map such that $\theta^*|_O: O \to \Xi^*$ is injective. If $\Xi$ is a closed linear subspace of $g$ and $\theta$ is the inclusion map $\Xi \hookrightarrow g$, then we say simply that $\Xi$ is a predual for the coadjoint orbit $O$.

The following statement provides a useful criterion for proving that condition (11) in Definition 2.2 is satisfied in the situation of Fréchet preduals (see for instance Sect. 7 in Ch. II of [Sch66]). Here $M_t(\cdot)$ stands for the space of complex Radon measures on some topological space.

**Proposition 2.6.** Let $g$ be a nilpotent locally convex Lie algebra with the Lie group $G = (g, \ast)$. If $(\Xi, \theta)$ is a predual for the coadjoint orbit $O \subseteq g^*$ such that $\Xi$ is barreled, then the linear mapping $F_{\Xi}: M_t(O) \to \mathcal{U}_b(\Xi)$, $\mu \mapsto \hat{\mu} \circ \theta$ is well defined and injective.

*Proof.* See [BB10f].

**Flat coadjoint orbits.** We now introduce some terminology that claims its origins in the results of [MW73] on representations of finite-dimensional nilpotent Lie groups.

**Definition 2.7.** Let $g$ be a nilpotent locally convex Lie algebra with the corresponding Lie group $G = (g, \ast)$, and denote by $z$ the center of $g$. We shall say that a coadjoint orbit $O$ is flat if the coadjoint isotropy algebra at some point $\xi_0 \in O$ satisfies the condition $g_{\xi_0} = z$.

**Proposition 2.8.** Assume that $g$ is a nilpotent locally convex Lie algebra with the Lie group $G = (g, \ast)$, and denote by $z$ the center of $g$. If $\dim z = 1$, the coadjoint orbit $O$ is flat, and $\xi_0 \in O$ satisfies the condition $\xi_0|_z \not\equiv 0$, then $\ker \xi_0$ is a predual for $O$ and the mapping $\ker \xi_0 \cong O, \quad X \mapsto (\text{Ad}_{G} X)\xi_0$ is a diffeomorphism.

*Proof.* See [BB10f].

**Weyl calculus on flat coadjoint orbits.**

**Setting 2.9.** Until the end of this section we assume the following setting:

- $g$ is a nilpotent locally convex Lie algebra with the Lie group $G = (g, \ast)$;
- the topological vector space underlying $g$ is barreled (for instance, $g$ is a Fréchet-Lie algebra);
- the center $z$ of $g$ satisfies the condition $\dim z = 1$;
- the coadjoint orbit $O \hookrightarrow g^*$ is flat, and $\xi_0 \in O$ satisfies $\xi_0|_z \not\equiv 0$;
- $\pi: G \to B(Y)$ is an irreducible unitary representation such that for every $X \in z$ we have $\pi(X) = e^{i(\xi_0, X)}\text{id}_Y$. 
In addition we shall denote Ξ := Ker ξ₀. This is a closed hyperplane in g, hence it is in turn a barreled space (see Sect. 7 in Ch. II of [Sch66]).

We have the linear isomorphism g/ξ ≃ Ξ, so Ξ is also a nilpotent Lie algebra. Let ∗ be the corresponding Baker-Campbell-Hausdorff multiplication. We also need the mapping s: Ξ × Ξ → Ξ, s(ξ₁, ξ₂) = ξ₁ ∗ ξ₂ ξ₁. □

**Definition 2.10.** For arbitrary Radon measures µ₁, µ₂ ∈ M₁(Ξ) we define their twisted convolution product µ₁ ∗₀ µ₂ ∈ M₁(Ξ) as the push-forward of the measure

\[ e^{i(ξ₀, s(X₁, X₂))} \mu₁ ⊗ \mu₂(X₁, X₂) ∈ M₁(Ξ × Ξ) \]

under the multiplication map Ξ × Ξ → Ξ, (ξ₁, ξ₂) → ξ₁ ∗₀ ξ₂.

**Theorem 2.11.** Let us assume that we have a locally convex space Γ such that there exists the continuous inclusion map Γ ↪ M₁(Ξ). Then the following assertions hold:

1. The linear mapping Γ → UC₀(Ξ), µ ↦ s[µ] is well defined and injective, and gives rise to the topological linear isomorphism F_Ξ: Γ → Q_Ξ (→ UC₀(Ξ)).
2. If a₁, a₂ ∈ Γ and (F_Ξ)⁻¹(a_j) ∈ Q_Ξ ∩ M₁(Ξ) for j = 1, 2, then

\[ Op(a₁)Op(a₂) = π((F_Ξj)⁻¹(a₁) ∗₀ (F_Ξj)⁻¹(a₂)) \]

Proof. See [BB10]. □

3. THE SPECIAL CASE OF INFINITE-DIMENSIONAL HEISENBERG GROUPS

**Infinite-dimensional Heisenberg groups.**

**Definition 3.1.** Let V be a real Hilbert space endowed with a symmetric injective operator A ∈ B(V).

The *Heisenberg algebra* associated with the pair (V, A) is h(V, A) = V + V + R with the Lie bracket \[[x₁, y₁, t₁], (x₂, y₂, t₂)] = (0, 0, (Ax₁ | y₂) − (Ax₂ | y₁)). This is a nilpotent Lie algebra. The corresponding Lie group H(V, A) = (h(V, A), ∗₀) is the *Heisenberg group* associated with (V, A), with the multiplication given by

\[(x₁, y₁, t₁) ∗ (x₂, y₂, t₂) = (x₁ + x₂, y₁ + y₂, t₁ + t₂ + ((Ax₁ | y₂) − (Ax₂ | y₁))/2)\]

whenever (x₁, y₁, t₁), (x₂, y₂, t₂) ∈ H(V, A). □

**Example 3.2.** If h(V, A) = V + V + R is a Heisenberg algebra and ξ₀ ∈ h(V, A) as in Definition 3.1, then it is easy to see that Ξ := V × V × {0} is a predual for the coadjoint orbit of ξ₀. □

**Remark 3.3.** Let LieGr denote the category of infinite-dimensional Lie groups modeled on locally convex spaces (see [Ne06]) and denote by QuadrHilb the category whose objects are the pairs (V, A) where V is a real Hilbert space and A ∈ B(V) is a symmetric, nonnegative, injective operator. The morphisms between two objects (V₁, A₁) and (V₂, A₂) in QuadrHilb, are defined as the continuous linear operators T: V₁ → V₂ satisfying the condition T∗A₂T = A₁. (Equivalently, T becomes an isometry if V_j is endowed with the continuous inner product (x, y) ↦ (Ax | y)V_j for j = 1, 2.)

Then we have a natural functor H: QuadrHilb → LieGr such that the image of any object (V, A) in QuadrHilb is the corresponding Heisenberg group.
\(\mathbb{H}(V, A)\) constructed in Definition 3.1. For every morphism \(T: (V_1, A_1) \to (V_2, A_2)\) in QuadrHilb as above, we have the corresponding morphism

\[
\mathbb{H}(T): \mathbb{H}(V_1, A_1) \to \mathbb{H}(V_2, A_2), \quad (x, y, t) \mapsto (Tx, Ty, t)
\]
in LieGr.

**Gaussian measures and Schrödinger representations.** Let \(V_-\) be a real Hilbert space with the scalar product denoted by \((\cdot | \cdot)\). For every vector \(a \in V_-\) and every symmetric, nonnegative, injective, trace-class operator \(K\) on \(V_-\) there exists a unique probability Borel measure \(\gamma\) on \(V_-\) such that

\[
(\forall x \in V_-) \quad \int_{V_-} e^{i(x|y)} - d\gamma(y) = e^{i(a|x)} - \frac{1}{2} (Kx|x)_-
\]

(see for instance [Bbg98, Th. 2.3.1]). We also have

\[
a = \int_{V_-} y d\gamma(y) \quad \text{and} \quad Kx = \int_{V_-} (x | y)_- \cdot (y - a) d\gamma(y)
\]

for all \(x \in V_-\), where the integrals are weakly convergent, and \(\gamma\) is called the **Gaussian measure with the mean \(a\) and the variance \(K\)**.

Let us assume that the Gaussian measure \(\gamma\) is centered, that is, \(a = 0\). Denote \(V_+ := \text{Ran} K\) and \(V_0 := \text{Ran} K^{1/2}\) endowed with the scalar products \((Kx | Ky)_+ := (x | y)_-\) and \((K^{1/2}x | K^{1/2}y)_0 := (x | y)_-\), respectively, for all \(x, y \in V_-\), which turn the linear bijections \(K: V_- \to V_+\) and \(K^{1/2}: V_- \to V_0\) into isometries. We thus get the real Hilbert spaces

\[
V_+ \hookrightarrow V_0 \hookrightarrow V_-
\]

where the inclusion maps are Hilbert-Schmidt operators, since \(K^{1/2} \in \mathcal{B}(V_-)\) is so. Also, the scalar product of \(V_0\) extends to a duality pairing \((\cdot | \cdot)_0: V_- \times V_+ \to \mathbb{R}\).

We also recall that for every \(x \in V_+\) the translated measure \(d\gamma(-x + \cdot)\) is absolutely continuous with respect to \(d\gamma(\cdot)\) and we have the Cameron-Martin formula

\[
d\gamma(-x + \cdot) = \rho_x(\cdot)d\gamma(\cdot) \quad \text{with} \quad \rho_x(\cdot) = e^{i(x|\cdot)} - \frac{1}{2} (x|x)_0.
\]

(This actually holds true for every \(x \in V_0\); see for instance [Bbg98, Cor. 2.4.3].)

**Definition 3.4.** Let \((V_+, A)\) be an object in the category QuadrHilb such that \(A: V_+ \to V_+\) is a nonnegative, symmetric, injective, trace-class operator. Denote the scalar product of \(V_+\) by \((x, y) \mapsto (x | y)_+\) and let \(V_0\) and \(V_-\) be the completions of \(V_+\) with respect to the scalar products \((x, y) \mapsto (x | y)_0 := (A^{1/2} | A^{1/2}y)\) and \((x, y) \mapsto (x | y)_- := (Ax | Ay)\), respectively. Then the operator \(A\) has a unique extension to a nonnegative, symmetric, injective, trace-class operator \(K \in \mathcal{B}(V_-)\) such that the above setting is recovered (see for instance [Beg06, Ch. 1, §1]), hence we get the centered Gaussian measure \(\gamma\) on \(V_-\) with the variance \(K\).

On the other hand, we can construct the Heisenberg group \(\mathbb{H}(V_+, A)\). The **Schrödinger representation** \(\pi: \mathbb{H}(V_+, A) \to \mathcal{B}(L^2(V_-, \gamma))\) is defined by

\[
\pi(x, y, t)\phi = \rho_{x+y}(1/2) e^{i(t+(y)_0 + \frac{1}{2}(x|y)_0)} \phi(-x + \cdot)
\]

whenever \((x, y, t) \in \mathbb{H}(V_+, A)\) and \(\phi \in L^2(V_-, \gamma)\). This is a continuous unitary irreducible representation of the Heisenberg group \(\mathbb{H}(V_+, A)\); see [Hob06, Th. 5.2.9 and 5.2.10].
Remark 3.5. We note that more general Schrödinger representations of infinite-dimensional Heisenberg groups are described in [Ne00, Prop. II.4.6] by using cocycles and reproducing kernel Hilbert spaces.

Remark 3.6. One way to see that the representation \( \pi: \mathbb{H}(V_+, A) \to B(L^2(V_-, \gamma)) \) of Definition 3.3 is irreducible is the following. For every integer \( n \geq 1 \) let \( V_{n,+} \) denote the spectral space for \( A \) corresponding to the interval \([1/n, \infty)\). That is, \( V_{n,+} \) is spanned by the eigenvectors of \( A \) corresponding to eigenvalues \( \geq 1/n \). Since \( A \) is a compact operator, it follows that \( \dim V_{n,+} < \infty \). We have

\[
V_1 \subseteq V_2 \subseteq \cdots \subseteq \bigcup_{n \geq 1} V_{n,+} \subseteq V_+
\]

and \( \bigcup_{n \geq 1} V_{n,+} \) is a dense subspace of \( V_+ \). Let us denote by \( A_n \) the restriction of \( A \) to \( V_{n,+} \). Then \( \mathbb{H}(V_{n,+}, A_n) \) is a finite-dimensional Heisenberg group, hence it is well known that its Schrödinger representation \( \pi_n: \mathbb{H}(V_{n,+}, A_n) \to B(L^2(V_{n,-}, \gamma_n)) \) is irreducible, where \( \gamma_n \) is the Gaussian measure on the finite-dimensional space \( V_{n,-} \) obtained out of the pair \( (V_{n,+}, A_n) \) by the construction outlined at the very beginning of Definition 3.3. Note that

\[
\mathbb{H}(V_1, A_1) \subseteq \mathbb{H}(V_2, A_2) \subseteq \cdots \subseteq \bigcup_{n \geq 1} \mathbb{H}(V_{n,+}, A_n) =: \mathbb{H}(V_+^+, A_+^+ \otimes \mathbb{1}_n)
\]

and \( \mathbb{H}(V_+, A_+^+) \) is a dense subgroup of \( \mathbb{H}(V_+, A^+) \), hence the Schrödinger representation \( \pi: \mathbb{H}(V_+, A^+) \to B(L^2(V_-, \gamma)) \) is irreducible if and only if so is its restriction \( \pi|_{\mathbb{H}(V_+, A_+^+)} \).

On the other hand, if we denote by \( \mathbb{1}_n \) the function identically equal to 1 on the orthogonal complement \( V_{n+1,+} \otimes V_{n,+} \), then it is straightforward to check that the operator

\[
L^2(V_{n,-}, \gamma_n) \to L^2(V_{n+1,-}, \gamma_{n+1}), \quad f \mapsto f \otimes \mathbb{1}_n
\]

is unitary and intertwines the representations \( \pi_n \) and \( \pi_{n+1} \). We can thus make the sequence of representations \( \{\pi_n\}_{n \geq 1} \) into an inductive system of irreducible unitary representations and then their inductive limit \( \pi|_{\mathbb{H}(V_+, A^+)} = \text{ind}_{n \to \infty} \pi_n \) is irreducible (see for instance [KS77]). As noted above, this implies that the Schrödinger representation \( \pi: \mathbb{H}(V_+, A^+) \to B(L^2(V_-, \gamma)) \) of Definition 3.3 is irreducible.

The infinite-dimensional pseudo-differential calculus of [AD99] and [AD98] can be recovered as a quasi-localized Weyl calculus for the Schrödinger representations introduced in Definition 3.3 above. Compare for instance [AD98, Prop. 3.7].
