Total Phenolic Content and Antioxidant Capacity of Polish Apple Ciders

A. KOWALCZYK*, M. RUSZKIEWICZ AND I. BISKUP
Department of Pharmacognosy, Wroclaw Medical University, Borowska 211, 50-556 Wroclaw, Poland

The total phenolic content and antioxidant capacity of three apple ciders produced in Poland were examined. The total phenolic content was determined by the Folin-Ciocalteau method and results were expressed in gallic acid equivalents with range from 0.21±0.003 to 0.30±0.004 mg/ml and Trolox equivalents ranging 0.88±0.012 to 1.24±0.015 mg/ml. The antioxidant activity was estimated by two methods: 2,2-diphenyl-1-picrylhydrazyl radical scavenging assay with results expressed as EC_{50} (ml/assay) and 2,2’-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid method with results expressed as Trolox equivalent antioxidant capacity. The antioxidant properties of tested ciders were correlated with total phenolic content. Additionally, the correlation between 2,2’-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid and 2,2-diphenyl-1-picrylhydrazyl radical scavenging methods was estimated.

Key words: Apple ciders, antioxidant capacity, phenolic content

Natural phenolic compounds are widely distributed in plants and are the main contributors to the antioxidant activities of food[1]. Many disorders, i.e. cancer, Parkinson’s and Alzheimer’s diseases, atherosclerosis or heart failure are connected with oxidative stress. Therefore the increasing interest in elucidating the antioxidant activity of different natural compounds in food and beverages is justified[2,3]. The antioxidant capacity of beverages can be examined by various methods based on different mechanism of reaction. The most popular methods for measurement of antioxidant capacity of food products are those involving stable radicals such as 2,2-diphenyl-1-picrylhydrazyl (DPPH) and 2,2’-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid (ABTS)[4]. Ciders have recently become object of great interest because of their antioxidant properties owe to their phenolics content[5-8] and their putative health-promoting effects[9,10]. Cider is possibly one of the oldest alcoholic beverage made from apple juice. It is produced in various countries around the world but is the most popular in i.e. Great Britain, France, Ireland, Spain, Denmark, Finland, Netherlands, Sweden, Germany and Belgium. Poland is not recognizable as a cider manufacturer even though it is one of the biggest apple producer in Europe with an annual production of 2.5 million

tons\(^{[11]}\). From several years Polish local producers have started making cider according to the standards obligatory in European Union countries. Only one Polish cider named “Jablecznik trzebnicki” has been registered and certificated as a Polish Traditional Product by the Polish Ministry of Agriculture and Rural Development\(^{[2]}\). These products have not been analyzed according to their antioxidant properties so far. The aim of this study was to evaluate the antioxidant activity of traditional Polish ciders “Jablecznik trzebnicki” in relation to their total phenolic content estimated by the Folin-Ciocalteau method.

The antioxidant activity was determined by ABTS and DPPH assays. Three apple ciders - A, B, C differed from each other by the batch number produced by Henryk Nowakowski, Trzebnica (Poland) were analyzed. All products were obtained by the fermentation of the juices of mixed autumnal apples i.e. Idared, Jonagold, Szampion without adding yeasts. Organic solvents and reagents were of analytical grade. Water was glass-distilled. Methanol (MeOH) was obtained from Merck (Germany), Folin-Ciocalteau (F-C) reagent was from Polskie Odczynniki Chemiczne (POCH). DPPH (2,2’-diphenyl-β-picrylhydrazyl), ABTS (2,2’-azinobis(3-ethylbenzothiazoline-6-sulfonic acid) diammonium salt) and potassium persulfate (dipotassium peroxdisulfate) were from Sigma-Aldrich. Gallic acid was purchased from Koch-Light Laboratories, UK, and Trolox (6-hydroxy-2, 5, 7, 8-tetramethychroman- 2-carboxylic acid) from Hoffman-La Roche. Total phenolic content was determined spectrophotometrically according to the method of Singleton and Rossi\(^{[13]}\). The diluted beverages (250 µl) were added to tubes and then, 250 µl F-C reagent, 500 µl of saturated sodium carbonate and 4 ml of distilled water were added immediately. Samples were vortexed and incubated for 30 min. at room temperature in the darkness. After 20 min incubation, the samples were centrifuged for 5 min at 4000 rpm and supernatants were used for spectrophotometric determination at 725 nm. Gallic acid and Trolox were used as standards and the results were expressed as GAE (gallic acid equivalents) and Trolox equivalents. The experimental method of DPPH radical - scavenging assay followed that of Brand-Williams\(^{[14]}\) and Karamać\(^{[15]}\). A methanol solution of DPPH (concentration 0.25 mg/ml) was prepared 2 h prior the analysis and kept away from light at room temperature. Appropriate amounts of diluted samples of each beverage (in MeOH) were added to tubes and filled with methanol. 0.25 ml of DPPH solution was added to all tubes, vortexed and left for 20 min in a dark place before taking the absorbance at 517 nm. Methanol was used as a blank solution. Experiments of ABTS scavenging assay were conducted according to Re and co-workers\(^{[16]}\) with small modifications. Trolox (2.5 mM) was prepared in methanol as a stock standard. Working solutions were prepared daily on the dilution with methanol. ABTS and potassium persulfate were dissolved in distilled water to a final concentration: 7 mM and 2.45 mM, respectively. These two solutions were mixed and kept in the dark at room temperature for 16 h before use. For the study of phenolic compounds, the ABTS radical solution was diluted with distilled water to an absorbance of 0.700 at 734 nm. Twenty microlitre µl of diluted samples of the beverages (in MeOH) were added to tubes and filled with methanol. 0.25 ml diluted samples of each beverage (in MeOH) were added to tubes and filled with methanol. 0.25 ml of DPPH solution was added to all tubes, vortexed and left for 20 min in a dark place before taking the absorbance at 517 nm. Methanol was used as a blank solution. The results were expressed as TEAC (Trolox equivalent antioxidant capacity). All data were the average of triplicate analyses. Mean values and standard deviations (SD) of all results have been determined. Statistical and correlation analyses of antioxidant activity was carried out by using Microsoft EXCEL program. The total phenolic content (TPC) was determined by the Folin-Ciocalteau method. Results were expressed in gallic acid equivalents (GAE) and Trolox equivalents.

Cider B had the highest phenolic content – 0.3±0.004 GAE and 1.24±0.015 Trolox (mg/ml). Slightly lower concentration had cider C – 0.28±0.002 GAE and 1.15±0.009 Trolox (mg/ml) and the lowest content was estimated for cider A – 0.21±0.003 GAE and 0.88±0.012 (mg/ml). DPPH and ABTS assays were performed to determine the antioxidant activity of ciders. Results from DPPH radical scavenging assay were expressed as EC\(_{50}\) (ml/assay). EC\(_{50}\) was calculated from percent of radical scavenging versus concentration curves of ciders. The order for antioxidant activity was cider B> cider C> cider A with following values 0.07, 0.08 and 0.12 ml/assay. It means that cider B seems to be a little bit stronger antioxidant than others in this test. Additionally, the antioxidant performance of examined ciders is depicted in fig. 1. The second

y=0.069x+0.058, R^2=0.973.

Table 1: Antioxidant Capacity of Analyzed Apple Ciders Samples

| Samples | TEAC (µmol Trolox/ml) |
|---------|-----------------------|
| Cider A | 2.21±0.04             |
| Cider B | 3.36±0.03             |
| Cider C | 3.28±0.05             |

Measurements in the ABTS radical scavenging assay (n=3). TEAC: Trolox equivalent antioxidant capacity, ABTS: 2,2’-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid correlations between antioxidant activity estimated in DPPH method and phenolic content (R^2=0.998) and between antioxidant activity evaluated in ABTS method and phenol content (R^2=0.973) confirmed that the antioxidant capacity of the analyzed products was for the most part due to their polyphenols. In addition, the correlation between ABTS and DPPH methods was estimated. ABTS and DPPH radical scavenging activities correlated in strong manner which confirmed that both methods are complementary to each other (R^2=0.986). The antioxidant capacity of ciders can be accurately determined by DPPH and ABTS assays. Both methods are fast, simple and useful. Optimized proper reaction time and reagent to analyte excess are crucial[5]. Total phenolic composition determined on the Folin-Ciocalteau assay was useful to predict the antioxidant activity of ciders. The differences of the antioxidant activities between all three ciders can be due to varieties of apples used in their production. Also this can be the reason of their lower total phenolic content in comparison to Spanish products published by Picinelli Lobo et al.[5]. Our study is the first report about antioxidant properties of traditionally Polish cider. The obtained results showed that among ciders from other European countries, Polish products have lower quantity of phenolic compounds. But due to their antioxidant activity they can have the beneficial effects on consumers’ health.

Phytochemical Screening, Proximate Analysis and Antioxidant Activity of Dracaena reflexa Lam. Leaves

ABHA SHUKLA*, SWATI VATS AND R. K. SHUKLA

Department of Chemistry, Kanya Gurukula Campus, Gurukula Kangri Vishwavidyalaya, Haridwar-249 407,
Department of Chemistry, Gurukula Kangri Vishwavidyalaya, Haridwar‑249 404, India

In the present study, the antioxidant activity of successive leaf extracts of Dracaena reflexa was investigated using the scavenging activity on 1,1‑diphenyl‑2‑picrylhydrazyl and reducing power by ferric reducing antioxidant power assay. Methanol extract was found potent in both the assays. IC50 values of 1,1‑diphenyl‑2‑picrylhydrazyl assay for methanol extract was 0.97 mg/ml and ferric reducing antioxidant power value for the same is 1.19. Phytochemical screening, proximate analysis and total phenolic content were also determined. Qualitative screening for phytochemical showed the presence of alkaloids, flavonoids, terpenoids, glycosides and saponins. Highest phenolic content was shown by methanol extract (49.69 mg gallic acid equivalent/g dry weight). Proximate analysis showed moisture content (3.31%), ash content (8.02%), crude fibre (1.31%), crude fat (0.97%), total protein (3.70%), total carbohydrate (86.01) and nutritive value (367.56 kcal/100 g), which would make it a potential nutraceutical. This study suggested that Dracaena reflexa, a potential natural free radical scavenger, which could find use as an antioxidative.

Key words: Dracaena reflexa, phytochemical, proximate, total phenolic content, antioxidant activity

Herbal medicine plays vital role in maintaining the health and wealth of mankind. Majority of world population use herbal medicines. The World Health Organization (WHO) reports that approximately 21,000 plants have been used for medicinal purposes [1]. Herbs have stood the test of time for their safety, efficacy, cultural acceptability and minimal side
