Abstract
Phosphatidylinositol phosphates (PIPs) function as important second messengers in many cellular events. In the human intestinal protist *Entamoeba histolytica*, where phagocytosis/trogocytosis plays an indispensable role in proliferation and pathophysiology during infection, various PIPs are involved in multiple steps of phago/trogocytosis. PI3-phosphate (PI3P) plays a pivotal role in the biogenesis of phagosome/troosomes via recruitment of PI3P effectors. Because no known PI3P downstream effectors are conserved in *E. histolytica*, we exploited a unique method to identify the proteins PI3P dependently recruited to phagosomes. We rationalised that overexpression of PI3P-binding GFP-HrsFYVE competes for PI3P on phagosomal membranes and results in dissociation of PI3P effectors from phagosomes. EhVps26 and EhVps35, but not sorting nexins (SNXs), of the retromer complex were detected from phagosomes only without GFP-HrsFYVE overexpression. Two potential SNXs, EhSNX1 and EhSNX2, identified in the genome, possess only phox homology domain and specifically bound to PI3P, but retromer components, EhVps26 and EhVps35, did not bind to PI3P. Live and immunofluorescence imaging showed that EhSNX1 was recruited to the trogocytic cup and tunnel-like structures, and subsequently, EhSNX2 was recruited to troosomes. Furthermore, EhSNX1, but not EhSNX2, specifically bound to Arp2/3 and EhVps26, which were localised to the tunnel-like structures and the troosomes, respectively. EhSNX2 gene silencing increased trogocytosis, suggesting that EhSNX2 plays an inhibitory role in trogocytosis.

1 | INTRODUCTION

Phosphatidylinositol (PI) is one class of glycerophospholipids that is composed of an inositol ring, a phosphate, a glycerol skeleton, and
two acyl chains. PI converts to seven types of phosphatidylinositol phosphates (PIPs): three types of PIP, three types of PIP₂, and one PIP₃. These seven different types of PIPs are localised on different cellular compartments and mediate a variety of the intracellular events by recruiting proteins possessing PIPs-recognizing domains such as FYVE (Fab1, YOTB1, Vac1, early endosomal antigen 1 [EEA1]), pleckstrin-homology, and phox homology (PX) domains. In mammalian cells, the forming phagocytic cup is partially decorated with PIP(4,5)P₂ and PIP(3,4,5)P₃, and subsequently with PIP₃ as the phagosome encloses. Each PIP species recruits specific effector proteins to endosomes and phagosomes to promote formation and maturation. For example, PIP₃ recruits FYVE domain-containing EEA1, which is recruited to early endosomes and facilitates endosome maturation, whereas Rabenosyn-5, hepatocyte growth factor-regulated tyrosine kinase substrate (Hrs), and endosomal sorting complex required for transport (ESCRT) complex are also recruited to PIP₃-rich membranes and play unique roles (Burman & Kistakos, 2010).

Entamoeba histolytica is the protozoan parasite that displays inherited capacity of ingestion of foreign cells by phagocytosis and trogocytosis ("trogo" means "nibble" or "chew" and thus, the word implies ingestion of live cells by pieces; Ralston, Solga, MacKey-Lawrence, Bhattacharya, & Petri, 2014) and responsible for human amebiasis causing an estimated 73,800 deaths annually (Lozano et al., 2012). Phagocytosis and trogocytosis have been implicated in self- and negative regulation of phagocytosis and trogocytosis. It has been shown that AGC kinase 1 is specifically involved in trogocytosis, whereas AGC kinase 2 is involved in both phagocytosis of dead mammalian cells and trogocytosis of live cells (Somlata, Nakada-Tsukui & Nozaki, 2017). Although PIP(3,4,5)P₃ effectors have been in part characterised, the identity of PIP₃ effectors remains to be investigated because of the promiscuity of lipid-binding specificities of FYVE domain-containing proteins, as shown for EhFP4, for instance.

In this study, we attempted to identify PIP₃ effectors recruited to phagosomes and trogosomes in a PIP₃-dependent fashion by proteome analysis of purified phagosomes under PIP₃-deprived (by overexpression of human HrsFYVE-GFP, using a tetracycline inducible system) and normal conditions. Finally, we proposed the model of how these sorting nexins (SNXs), the PIP₃ effectors, are involved in both positive and negative regulation of phagocytosis and trogocytosis.

## 2 | RESULTS

### 2.1 | Identification of retromer complex components as potential PI3P effectors that were recruited to phagosomes

To identify PIP₃-binding effectors that are involved in the phagosome biogenesis, particularly on the late stage of maturation, in *E. histolytica* trophozoites, we opted to utilise differential proteomic analysis of the phagosomes under normal versus PIP₃-deprived (competed) conditions. We rationalised that overexpression of a soluble PIP₃-binding protein should compete for PIP₃ with other PIP₃ effectors that play a role in phagosome maturation to be recruited (Figure 1a). To this end, the *E. histolytica* strain that expresses GFP-fused HrsFYVE, which is the well-documented human PIP₃-binding domain (Nakada-Tsukui et al., 2009) in a tetracycline-inducible fashion, was established. Expression of GFP-HrsFYVE in *E. histolytica* peaked at 24 hρ of cultivation with 10 μg/ml of tetracycline (Figure S1). At this time point, we confirmed by immunofluorescence assay (IFA) that GFP-HrsFYVE was localised on the phagosomes containing human serum-coated Dynabeads (Figure 1b). We verified the purity of the phagosome-enriched fraction by the significant enrichment of GFP-HrsFYVE (Figure 1c) and the mature CP-A5 in the phagosome-enriched fraction. Altogether, these results suggest that our protocol of phagosome purification using serum-coated Dynabeads allowed us to successfully enrich phagosomes that were associated with GFP-HrsFYVE and thus PIP₃, on phagosome membranes (Figure 1c). We isolated phagosomes using previously established protocols (Marion, Laurent, & Guillén, 2005) and analysed their proteome under the conditions of GFP-HrsFYVE being expressed and non-expressed. After all detected proteins were categorised by their functions, those detected at least two-fold higher under the GFP-HrsFYVE non-expressed condition compared with those under the GFP-HrsFYVE expressed condition were considered to be potential candidates of PIP₃-binding proteins (Table S1). Only proteins categorised to lipid metabolism and vesicular trafficking are shown in Figure 1d. Among them, vacuolar protein sorting (Vps) 26 and Vps35, both of which are the components of the retromer complex, were detected, which were mainly investigated in this study, whereas analysis of other components will be described elsewhere.

### 2.2 | In silico identification of SNXs in *E. histolytica*

In mammalian cells, the retromer complex is known to be involved in recycling of transmembrane receptors from endosomes to the trans-Golgi network (Borifacino & Hurley, 2008). It has been demonstrated that the retromer complex consists of two subcomplexes: the major subcomplex of Vps26/Vps29/Vps35 and a combination of SNX1 or 2, SNX5 or 6, and SNX3. The retromer is recruited to PIP₃-rich endosomes via PX domain of SNX3 (Seaman, 2012). The components of the major subcomplex (Vps26/Vps29/Vps35) have been identified and investigated in *E. histolytica* (Nakada-tsukui et al., 2005; Picazarrri et al., 2015; Srivastava et al., 2017).
FIGURE 1  Identification of PI3P-binding effector proteins involved in phagosome biogenesis. (a) The strategy and rationale used in this study to identify PI3P-binding effector proteins involved in phagosome biogenesis. See text for details. (b) Verification of the recruitment of GFP-HrsFYVE to phagosomes by fluorescence microscopy. The Entamoeba histolytica transformant cells that expressed GFP-HrsFYVE under tetracycline induction were cultured in the presence of 10 μg/ml of tetracycline for 24 hr and then incubated with human serum-coated beads for 30 min. Arrowheads indicate ingested beads. (c) Validation of the recruitment of GFP-HrsFYVE to phagosomes by phagosome purification followed by immunoblot analysis. The bead-containing phagosomes were purified as described in Section 4 and subjected to SDS-PAGE and immunoblot analyses. GFP-HrsFYVE and mature CP-A5 were detected with anti-myc, anti-GFP, and anti-CP-A5 antibody, respectively. (d) The categorised list of proteins that are differentially excluded from phagosomes in GFP-HrsFYVE-dependent fashion. Tet(+) and tet(−) indicate the conditions where GFP-HrsFYVE expression was induced with 10 μg/ml of tetracycline or not induced. The values indicate the relative frequency of the detected peptides corresponding to each protein. “tet(−)/tet(+)” indicates the division of the value of tet(−) by the value of tet(+). A whole list of the detected proteins from purified phagosomes are found in Table S1.
However, it remains elusive whether or not SNXs are also conserved in *E. histolytica* and if they are, what the roles of SNXs in vesicular traffic are, particularly during phagocytosis and trogocytosis. There are several classes of SNXs known in mammals: those with PX and BAR (Bin/Amphiphysin/Rvs) domains, those with PX domain and other domain such as FERM, PDZ, and SH3 domains, and those containing PX domain only (Worby & Dixon, 2002). Human SNX1 or SNX3 belongs to the first or third group, respectively (Cullen, 2008). Human SNX3 is responsible for recruiting the retromer complex to the membrane of late endosomes via binding to PI3P (Seaman, 2012). Human SNX3 is phosphorylated on Ser72 (Lenoir et al., 2018). When phosphorylated, it cannot bind to PI3P and is localised to the cytosol.

We conducted an in silico survey of SNX genes in the *E. histolytica* genome. We used SNX1 isoform a (NP_003090.2) from *Homo sapiens* as a query for Blastp. We identified two proteins encoded by EHI_060320 and EHI_004400 as possible SNX homologs (E-value of 4e-6 and 1e-4, respectively). Both of the proteins have a PX domain but lack any other recognisable domains, and thus, based on domain configuration, they are considered to be orthologous to human SNX3. These *E. histolytica* SNX orthologs were designated as EhSNX1 and EhSNX2. Alignment of EhSNX1, EhSNX2, and human SNX3 protein sequences shows that the residue corresponding to conserved Ser72 (conserved among about the half of human SNXs) is conserved in the PX domain of EhSNX1 (Ser132) and EhSNX2 (Ser53; Figure 2). Two out of four residues shown to be involved in the binding to PI3P are conserved in EhSNX1 and EhSNX2. Three out of ten residues implicated in the binding to Human Vps26 and Vps35 are conserved in EhSNX1, but not in EhSNX2, suggesting a possibility of isotype-specific interactions with EhVps26 and EhVps35. It is also worth noting that EhSNX1, but not EhSNX2, has an approximately 60 a.a.-long amino terminal extension and a 10 a.a.-long carboxyl terminal extension rich in serine and negatively charged amino acids, which may be involved in protein-protein interaction.

### 2.3 Determination of EhSNXs binding specificity to PI3P

To investigate whether EhSNX1 and EhSNX2 bind to PIIPs and, if so, what PIIP species they bind, we created *E. histolytica* lines that expressed EhSNX1 and EhSNX2 with HA tag. A single band corresponding to the expected molecular mass of HA-EhSNX1 (27.7 + 3 kDa for the HA tag) or HA-EhSNX2 (17.0 + 3 kDa for the HA tag) was observed in the respective transformants (Figure 3a). The lipid overlay assay using amebic lysates from these transformants showed that both EhSNX1 and EhSNX2 specifically bound to PI3P (Figure 3b). We also verified the lipid-binding activity of some PI3P-binding protein candidates in the proteome list (Figure 1d) by lipid overlay assay: β-adaptin, Vps35, Vps26, and Syntaxin. However, they did not bind to any phospholipids including PI and PIIPs (data not shown).

### 2.4 Immunofluorescence imaging showing colocalisation of EhSNXs with EhVps26

As EhSNXs were shown to bind to PI3P and thus, work as PI3P effectors, they were expected to be localised to PI3P-rich membranes (compartments) during phagocytosis and trogocytosis. Because it was not clear whether EhSNXs make complex with the other major retromer subcomplex, we investigated whether EhSNXs are colocalised with Vps26 during trogocytosis of Chinese hamster ovary (CHO) cells by IFA using HA-EhSNX1- and HA-EhSNX2-expressing strains. In steady state, both EhSNX1 and EhSNX2 were localised on some small vesicles associated with EhVps26 (Figure 4a,b). To investigate the localisation and kinetics of EhSNXs during trogocytosis, we performed IFA at 15 min after addition of CellTracker Blue-stained live CHO cells to *E. histolytica* trophozoites. EhSNX1 was localised on the bottom of the trogocytic cup associated with EhVps26 (Figure 4a). EhSNX1 appeared to be dissociated from the trogosome after phagocytic cup membrane

**FIGURE 2** Alignment of protein sequences of EhSNX1, EhSNX2, and HsSNX3. Protein sequences were aligned using clustalw algorithm (http://clustalw.ddbj.nig.ac.jp). Phox homology domain sequences were predicted by HMMER (Meng & Ji, 2013) and are shown with yellow background. The numbers by three amino acid sequences (EhSNX1, EhSNX2, and HsSNX3) correspond to the a.a. positions of each protein, whereas those on top of the sequences (Arg69, Ser72, Lys95, Ile109, and Arg118) correspond to the positions of the residues in HsSNX3 (Lenoir et al., 2018). Ser72 was previously shown to be phosphorylated and marked with a blue rectangle, whereas the other residues implicated for PI3P binding are marked with red rectangles. Important residues for binding to Vps26 and Vps35 are shown with blue and pink background, respectively.
was incubated with total lysates from HA panel of PIPs and phospholipids spotted on nitrocellulose membrane specificity of EhSNX1 and EhSNX2 observed by lipid overlay assay. A detected by anti lysates from these strains were loaded. Cysteine synthase 1 was expressing transformants. The membranes were reacted with anti 1 phosphatidylethanolamine; PS, phosphatidylserine; S1P, sphingosine phosphatidic acid; PC, phosphatidylcholine; PE, antibody. LPA, lysophosphatidic acid; LPC, lysophosphocholine; PA, phosphatidic acid; PC, phosphatidylycholine; PE, phosphatidylethanolamine; PS, phosphatidylserine; S1P, sphingosine-1-phosphate was incubated with total lysates from HA-EhSNX1- and HA-EhSNX2-expressing transformants by immunoblotting using anti-HA antibody. Approximately 20 μg of total lysates from these strains were loaded. Cysteine synthase 1 was detected by anti-CS1 antiserum as a loading control. (b) Lipid-binding specificity of EhSNX1 and EhSNX2 observed by lipid overlay assay. A panel of PIPs and phospholipids spotted on nitrocellulose membrane was incubated with total lysates from HA-EhSNX1- and HA-EhSNX2-expressing transformants. The membranes were reacted with anti-HA antibody. LPA, lysophosphatidic acid; LPC, lysophosphocholine; PA, phosphatidic acid; PC, phosphatidylycholine; PE, phosphatidylethanolamine; PS, phosphatidylserine; S1P, sphingosine-1-phosphate

2.5 | Live imaging and quantification of GFP-EhSNX1/2 during trogocytosis

We monitored (Movies S1 and S2) and quantified (Figure 5) GFP-EhSNX1/2 on the trogocytic cup (and tunnel-like structures) and the trogosome during trogocytosis, according to the protocol described in Section 4. GFP-EhSNX1 was recruited to the trogocytic cup when the cup was formed and remained associated until 108 s (note that the movie started to be recorded 4–7 s after adherence; Movie S2, Figure 5). The intensity of GFP-EhSNX1 was detected after the attachment of the trophozoite to the CHO cell and gradually decreased during trogosome maturation. On the contrary, GFP-EhSNX2 was recruited to the trogosome after the trogocytic cup was enclosed (Movie S2). The signal of GFP-EhSNX2 remained low until 108 s; it suddenly increased at 124 s (Figure 5). This live imaging suggests sequential processes in which GFP-EhSNX2 recruitment to the trogosome occurred after GFP-EhSNX1 dissociation from the trogosome.

2.6 | Interaction between EhSNX1 and the retromer complex demonstrated by immunoprecipitation

To demonstrate physical interaction between EhSNX1/2 and EhVps26 containing the retromer complex during trogocytosis, immunoprecipitation was performed with anti-EhVps26 antiserum using lysates from EhSNX1-HA expressing cells. Expression of EhSNX1-HA was confirmed by immunoblot analysis using anti-HA antibody (Figure 6a). For unknown reasons, EhSNX2-HA-expressing transformant could not be established (data not shown), and HA-EhSNX2 was used as control. Because EhSNX1 was found on the trogocytic cup/trogosome during trogocytosis of CHO cells, EhSNX1-HA-expressing cells were coincubated with CHO cells for 30 min and then, subjected to immunoprecipitation with anti-EhVps26 antiserum, followed by immunoblot analysis using anti-HA antibody, anti-EhVps26, and anti-EhVps35 antisera. EhVps26, EhVps35, and, in a lesser amount, EhSNX1-HA were immunoprecipitated from EhSNX1-HA-expressing cells (Figure 6b). HA-EhSNX2 was not coprecipitated with EhVps26, suggesting that the interaction with EhVps26 was specific to EhSNX1, but not EhSNX2.

2.7 | Interaction between Arp 2/3 complex component and EhSNX1 demonstrated by immunoprecipitation

To further understand the role of EhSNX1, immunoprecipitation was performed using the strain expressing EhSNX1 with the amino-terminal HA. HA-EhSNX1 was precipitated with anti-HA agarose after coincubation with CHO cells for 30 min. One specific band around 20 kDa was detected after SDS-PAGE and silver staining (Figure 7a) and subjected to mass spectometry analysis (Figure 7b). Notably, two of eight detected proteins (EHI_174910; EHI_030820) were C3 and C4 components of actin-related protein (Arp) 2/3 complex. To verify the interaction, the strain expressing FLAG-tagged 2/3 complex subunit 3 (EhArpC3; FLAG-EhArpC3) was established. The FLAG-EhArpC3 localization was examined by IFA using anti-FLAG antibody. FLAG-EhArpC3 was localised on the tunnel-like structure (corresponding to the neck of a flask) during trogocytosis of CHO cells (Figure 7c). On the other hand, EhVps26 was never found on the tunnel-like structure, but on the bottom region of the trogocytic cup (before closure) and on the trogosome (after closure).
2.8 | Transcriptional gene silencing of EhSNX1 gene reduced recruitment of EhVps26 to the trogosome, whereas that of EhSNX2 gene upregulated trogocytosis

To better understand how EhSNXs are involved in trogocytosis and phagocytosis, we performed transcriptional gene silencing (gs) of EhSNX1 and EhSNX2 genes. In the parental G3 line transformed with the mock vector, the level of EhSNX2 mRNA is approximately 3.0-fold higher than that of EhSNX1. The level of EhSNX1 transcript was reduced by 81% by EhSNX1 gene silencing, whereas that of EhSNX2 was conversely increased by 41% (Figure 8a). In contrast, the level of EhSNX1 and EhSNX2 transcripts was reduced by 55% and 94% by EhSNX2, respectively (Figure 8a).

Because EhSNX1 physically interacts with the major retromer subcomplex (see above), gene silencing of EhSNXs can potentially affect localisation of the complex during trogocytosis and phagocytosis and also efficiency of ingestion. EhVps26 was swiftly recruited, together with EhSNX1, to the trogocytic cup during trogocytosis of CHO cell (Figure 4a). Almost all (96%) of CHO cell-containing trogosomes in the control strain were decorated with EhVps26 at 10
At 30 min, a slightly less proportion (81%) of trogosomes in the control were still decorated with EhVps26. Although statistically insignificant (p value .44 and .11, at 10 and 30 min, respectively), gene silencing of EhSNX1 caused less recruitment of EhVps26 to trogosomes compared with the control (4% and 14% reduction compared with the control at 10 and 30 min, respectively). Gene silencing of EhSNX2 caused no change in the association of EhVps26 with trogosomes at 10 and 30 min. Next, we measured the total volume of ingested CHO cells per trophozoite, in EhSNX1gs, EhSNX2gs, and mock strains, on image cytometer CQ1 to estimate the efficiency of trogocytosis. The amoebic transformants were cultivated with CHO cells, and images were captured every 10 min for 80 min. Interestingly, trogocytosis significantly increased by 1.4- to 2.0-fold in EhSNX2gs strain compared with the control at all time points (p < .05; Figure 8c). On the other hand, the volume of ingested CHO cells was not changed in EhSNX1gs strain at any time point. Phagocytosis was also affected by EhSNX2 gene silencing; the volume of ingested prekilled CHO cells increased by 1.4- to 2.0-fold in EhSNX2gs strain at all time points, similar to the effects on trogocytosis (Figure S4).

3 | DISCUSSION

3.1 | EhSNX1/2 are downstream effectors of PI3P signals on the trogosome membrane

PIPs-mediated signalling plays a pivotal role in phagocytosis and trogocytosis in E. histolytica. In this study, we identified for the first
time the retromer complex, in particular SNXs, as a PI3P downstream effector on the phagosome and trogosome membrane in *E. histolytica*. It has been well established that in mammalian cells, PI3P is recruited to phagosomes and trogosomes after complete closure of the phagocytic/trogocytic cup and formation of the phagosome/trogosome, and that PI3P effectors such as EEA1 is recruited to the enclosed phagosomes to facilitate maturation of phagosome/trogosomes. It has been shown in *E. histolytica* that PI3P is localised on the phagocytic cup before closure as well as on the enclosed phagosomes (Nakada-Tsukui et al., 2009), and the timing of PI3P recruitment to the phagocytic and trogocytic cup in *E. histolytica* appears to be different from human cells (Yeung & Sergio, 2007). However, as no known PI3P effector homologs were found in the *E. histolytica* genome, the role of PI3P on the phagocytic/trogocytic cup and phagosome/trogosome and its downstream effectors remained elusive. To identify the proteins that are recruited to phagosomes in a PI3P-dependent manner, we took a unique approach using our unique reverse genetic system in which PI3P-binding Hrs FYVE domain fused with GFP, expressed in a tetracycline-inducible manner, competes with endogenous PI3P binding proteins for PI3P on phagosome and trogosomes. Because such interaction between PI3P and its effectors is transient and unstable, we needed to use a

![FIGURE 7](image)

**FIGURE 7** Identification of candidate binding proteins of EhSNX1. (a) Silver-stained SDS-PAGE gel of the immunoprecipitated samples from HA-EhSNX1 and mock transformants using anti-HA antibody. The rectangles indicate the region of the specific band excised from HA-EhSNX1 and its corresponding region from control. (b) The proteins that were detected from the unique band specifically recognised from HA-EhSNX1-expressing transformants by immunoprecipitation using anti-HA antibody. Proteins that were not detected from the HA-EhSNX1 are excluded from the table. The values indicate the relative frequency of the detected peptides corresponding to each protein. “HA-EhSNX1/HA” indicates the division of the value of HA-EhSNX1 by the value of HA control. A whole list of the detected proteins is found in Table S2. (c) The localisation of EhArpC3 and EhVps26 during trogocytosis. FLAG-EhArpC3 transformant was co-cultured with CHO cells stained with CellTracker Blue for 15 min. FLAG-EhArpC3 and EhVps26 were detected using anti-FLAG antibody and anti-EhVps26 antiserum, respectively. FLAG-EhArpC3 is shown in green; EhVps26 is shown in red. Scale bar is 10 μm.
FIGURE 8  The effect of gene silencing of EhSNX1 and EhSNX2 on the retromer recruitment to trogosomes and trogocytosis. (a) The levels of EhSNX1 and EhSNX2 transcripts in EhSNX1gs, EhSNX2gs, and control strains. The transcript levels are shown relative to that of RNA polymerase II. (b) The effects of gene silencing of EhSNX1 and EhSNX2 on the recruitment of EhVps26 to trogosomes. Trophozoites were allowed to ingest live Chinese hamster ovary (CHO) cells for 10 or 30 min and subjected to immunofluorescence assay. Images of trophozoites that had ingested CHO cells were randomly captured, and the number of all trogosomes and Vps26-positive trogosomes were counted to estimate the ratio of Vps26-positive trogosomes. (c) The effects of gene silencing of EhSNX1 and EhSNX2 genes on trogocytosis. Trophozoites of EhSNX1gs and EhSNX2gs strains stained with CellTracker Green were incubated with CHO cells stained with CellTracker Blue as described in Section 4. The images were taken on CQ1 every 10 min for 80 min. The volume of the ingested CHO cells (blue) was calculated using three-dimensionally reconstituted data. Bars indicate standard errors. Asterisks indicate statistical significance by Tukey test (p < .05). Experiments were conducted three times independently, and a representative data set is shown.
cross-linker and a phosphatase inhibitor to immobilise such interaction (Figure S2).

SNXs were not identified from *E. histolytica* in our previous study by biochemical approaches (Nakada-Tsukui et al., 2005). Furthermore, an in silico gene survey also failed to identify SNX homologs (Nakada-Tsukui et al., 2005), which was likely due to our use of yeast Vps5p as a query for Blastp search. *E. histolytica* SNXs were identified when human SNX1 or SNX3 was used as a query, but not by using PX domain from other protein as a query (the E-values of the Blastp search using HsSNX1 or HsSNX3 as a query were 4e-6 and 5e-10 for EHI_060320, respectively; 1e-04 and 3e-13 for EHI_004400; whereas that using yeast Vps5p was 0.007 for EHI_060320 and 0.002 for EHI_004400).

### 3.2 PIP specificity of EhSNX1/2 and human SNXs

The PIP specificity of EhSNX1 and EhSNX2 compared with that of human SNX1-3 is intriguing. In humans, there are >30 members of SNXs known (Cullen, 2008) containing several members with known PIP specificity. Human SNX1 and SNX2 showed preference in the order of PI(3,4,5)P3 > PI(3,5)P2 > PI3P and PI3P > PI4P > PI5P, respectively, whereas human SNX3 almost exclusively binds to PI3P, similar to EhSNX1 and EhSNX2 (Worby & Dixon, 2002). Amino acid alignment shows six amino acid residues that are shared by EhSNX1, EhSNX2, and HsSNX3, but not conserved in both HsSNX1 and HsSNX2, including EhSNX1 T107 of (EhSNX2 T28), EhSNX1 Y131 (EhSNX2 Y53), EhSNX1 L160 (EhSNX2 L82), EhSNX1 G162 (EhSNX2 G84), EhSNX1 F175 (EhSNX2 F96), and EhSNX1 I191 (EhSNX2 I112; Figure S3). The conservation of EhSNX1 G162 (EhSNX2 G84) corresponding to HsSNX3 G94 is of particular interest as these residues are also exclusively present in HsSNX1-13 and 27 (Lenoir et al., 2018), among which PIP specificity of only HsSNX13 was shown: preferred binding to PI3P and PI5P over PI(3,5)P2 and PI4P (Worby & Dixon, 2002). These data suggest that EhSNX1 G162 (EhSNX2 G84) potentially contributes to PI3P specificity. Although PIP specificity may be affected by other domains than PX for the proteins that contain multiple domains such as HsSNX13 (Cullen, 2008), those of EhSNX1 and EhSNX2 are likely to be attributable to only the PX domain, similar to HsSNX3.

### 3.3 EhSNX1 and EhSNX2 have different roles during trogocytosis

Two SNXs from *E. histolytica* have similar domain structure (containing only PX domain, but lacking BAR domain) and lipid-binding specificities, but showed distinct patterns of localisation and trogosome/phagosome recruitment, and phenotypes by gene silencing. We have shown by biochemical, genetic analyses and live imaging that EhSNX1, but not EhSNX2, is involved in the recruitment of EhVps26 during trogocytosis. We have also shown that EhSNX2 is negatively involved in trogocytosis per se, as demonstrated with partial augmentation of trogocytosis by EhSNX2 gene silencing. Our data indicate, together with our previous finding showing that EhVps26 of the retromer complex is recruited to the trogocytic cup (Nakada-Tsukui et al., 2005; Picazarri et al., 2015), that EhSNX1 recruits the retromer complex to the trogosome/phagosome in a PI3P-dependent manner. Unlike EhSNX1, EhSNX2 did not interact with the retromer complex as indicated. This result is consistent with the fact that the amino acid residues implicated for the binding with the retromer complex are not conserved in EhSNX2 (see Figure 2 and Section 2.2).

The fact that gene silencing of EhSNX2, but not EhSNX1, increased the trogocytosis efficiency was counter-intuitive and suggestive of EhSNX2 being a negative regulator of trogocytosis. It has been shown that in dendritic cells, SNX3 overexpression causes defect in early endosome maturation by competing PI3P on early endosomes and reducing EEA1 recruitment (Chua & Wong, 2013). This observed phenotype may mirror the apparent upregulation of trogocytosis by EhSNX2 gene silencing. However, the loss of competition for PI3P by EhSNX2 gene silencing may not be the reason of the observed upregulation of trogocytosis because no change in trogocytosis was observed by EhSNX1 gene silencing, which in theory also causes reduced competition for PI3P. The lack of phenotype by EhSNX1 gene silencing may be explained at least in part by compensatory upregulation of EhSNX2 gene expression by EhSNX1 gene silencing. One possible scenario to explain these phenotypic changes in both human and *E. histolytica* is that both HsSNX3 and EhSNX2 employ a possible negative downstream effector/machinery needed for maturation of early endosomes and trogosomes.

### 3.4 EhSNX1 binds to Arp2/3 complex for downstream signalling to cytoskeletal rearrangement during trogocytosis

We demonstrated that EhSNX1 specifically bound to ArpC3/ArpC4 of the Arp2/3 complex. ArpC3 and ArpC4 were found to interact with EhSNX1 as indicated by LC/MS/MS analysis of the immunoprecipitated samples using HA-EhSNX1 as a bait. In general, Arp2/3 complex is known to be composed of seven subunits and involved in elongation, branching, and cross-linking of actin filaments via regulation of actin nucleation and elongation (Goley & Welch, 2006). Because all components of the Arp2/3 complex were found in the previous phagosomal proteome analyses (Boettner et al., 2008; Furukawa, Nakada-tsukui, & Nozaki, 2013; Marion et al., 2005; Okada et al., 2006), the Arp2/3 complex was suggested to be involved in phagocytosis and trogocytosis. The recruitment of EhSNX1 to the trogocytosis initiation site was specific to EhSNX1 and not observed for EhSNX2. Precise timing of the recruitment of EhSNX1 to the trogocytosis initiation site relative to that of Arp2/3 was not determined as live imaging was unable to be performed. However, the recruitment of EhSNX1 appeared to slightly precede that of Arp2/3. The continuity of the association of EhSNX1 and Arp2/3 clearly indicates close and direct interplay between them, triggered by PI3P-dependent recruitment of EhSNX1 to the trogocytosis initiation site. It is worth noting that the localisation of EhVps26 and
EhArpC3 on the trogocytic cup were overlapping but not identical. Together with the observation that EhSNX1 partially colocalised with EhVps26, these observations indicate that EhSNX1 may play a role in the bridging cytoskeletal rearrangement by EhArpC3 and receptor recycling mediated by the retromer.

3.5 | The model proposed by EhSNX1/2 live imaging

Based on the biochemical, live imaging, and immunofluorescence image data, we propose the following model of how key players are engaged during trogocytosis (Figure 9). Upon the adherence of the amoebic trophozoite to the live mammalian cell, PI3P is locally synthesised in situ on the trogocytosis initiation site. EhSNX1 is recruited via PI3P binding mediated by its PX domain to the trogocytosis initiation site, which then becomes the trogocytic cup. EhSNX1 recruits Arp2/3 complex, which subsequently leads to actin cytoskeleton reorganisation needed for the establishment of the tunnel-like structure of the trogosomes and also the closure of trogosomes. At the same time, EhSNX1 also recruits the retromer complex via interaction with Vps26. The retromer complex then binds to the hydrolase receptors for the retrieval (and recycling) of the receptors. Once the trogocytic cup (or the trogosome) is enclosed, EhSNX2 is recruited to the trogosome by virtue of its PI3P-binding ability with a concomitant dissociation of EhSNX1. This model depicts a sequential involvement of EhSNX1 and EhSNX2 during the formation and maturation of trogosomes.

The apparent enhancement of trogocytosis by EhSNX2 gene silencing is possibly due to the loss of negative feedback regulation toward the initial trogocytosis event(s) as explained above. However, its mechanism and the possible negative effector(s) remain elusive and need further investigation. The recruitment of EhSNX1 and 2 to the trogocytic cup and the trogosome was time- and localisation (domain)-specific. Although the underlying mechanism of the spatiotemporal recruitment of EhSNXs remains unknown, it is plausible that phosphorylation of the conserved Ser72 (of HsSNX3; Figure S3) may regulate the binding of EhSNX1/2 to PI3P and other possible accessory and effector proteins in an isotype-specific manner.

The retromer complex was previously identified as an effector of GTP-bound active Rab7A in *E. histolytica* (Nakada-Tsukui et al., 2005). EhRab7A was reported to be localised to the preparatory vacuolar organelle that emerges upon erythropagocytosis (pre-phagosomal vacuole), where EhRab7A and EhVps26 were colocalised. In this study, the effects of EhSNX1 gene silencing on the inhibition of Vps26 recruitment to the trogosome was not large and rather marginal, suggesting that the recruitment of the retromer may be also regulated via EhRab7A.

4 | EXPERIMENTAL PROCEDURES

4.1 | Cells and reagents

Trophozoites of *E. histolytica* strains HM-1:IMSS cl6 (Diamond, Mattern, & Bartgis, 1972) and G3 (Bracha, Nuchamowitz, & Mirelman, 2003) were axenically cultured in BI-S-33 medium (BIS) at 35.5°C as previously described (Diamond et al., 1978). CHO cells were maintained in F-12 medium (Invitrogen-Gibco, Grand Island, NY) supplemented with 10% fetal bovine serum in 25 cm² tissue culture flasks (IWAKI, Shizuoka, Japan) under 5% CO₂ at 37°C. All chemicals of analytical grade were purchased from Sigma-Aldrich (Missouri, USA) unless otherwise stated. The anti-HA (11MO) and anti-myc (9E10) monoclonal antibodies were purchased from Covance (Princeton, NJ, USA). The anti-GFP antibody was purchased from Sigma-Aldrich. The production of rabbit polyclonal antibodies against EhCS1, EhCP-A5, EhVps26, and EhVps35 were previously...
described (Nakada-Tsukui et al., 2005; Nakada-Tsukui et al., 2009; Nozaki et al., 1999).

4.2 Plasmid construction

Standard techniques were used for DNA manipulation, subcloning, and plasmid construction. Plasmid vectors to produce E. histolytica lines that express EhSNX1 (EH1_060320) and EhSNX2 (EH1_004400) with HA- or GFP-tag fused at the amino and carboxyl termini were constructed as follows. The full-length protein coding region of these genes was amplified by polymerase chain reaction (PCR) with the following primers: 5′-GAACCCGGGATGGAGATAAAGAGATATTAT-3′ and 5′-GAACTCGAGTTTCTCGATGATGATGAACTTTTGAT-3′ (EhSNX1) or 5′-GAACCCGGGATGAGTAATTATGACAGTGATGAACTTTTGAT-3′ and 5′-GAACTCGAGTTTCTCGATGATGATGAACTTTTGAT-3′ (EhSNX2), where the restriction enzyme sites are underlined. PCR-amplified fragments were digested by XmaI and XhoI and ligated into pEhEx-HA (Nakada-Tsukui et al., 2009) and pEhEx-GFP vectors (Somlata et al., 2017) that were predigested with the two enzymes and purified to construct the plasmid to produce HA-tagged and GFP-fused SNXs at the amino terminus. The resultant plasmids were designated as pEhExHA-SNX1, pEhExHA-SNX2, pEhExFLAG, pEhExGFP, pEhExGFP-SNX1, and pEhExGFP-SNX2, respectively. Note that pEhExGFP contains a linker corresponding to five repeats of GA dipeptides) after GFP. To construct plasmids to express EhSNX1 and EhSNX2 with HA tag at the carboxyl terminus, the full-length protein coding sequence of these genes was amplified by PCR with the following primers: 5′-GAACTCTATGGGAGATAAAGAGATATTAT-3′ and 5′-GAACTCGAGTTTCTCGATGATGATGAACTTTTGAT-3′ (EhSNX1); 5′-GAACCCGGGATGAGTAATTATGACAGTGATGAACTTTTGAT-3′ and 5′-GAACTCGAGTTTCTCGATGATGATGAACTTTTGAT-3′ (EhSNX2), where restriction enzyme sites are underlined. Amplified fragments were digested by BglII and ligated into pEhEx-HA. To construct plasmids for gene silencing of EhSNX1 and EhSNX2, initial 420 bp of the EhSNX1 coding region and full length (426 bp) of EhSNX2 were PCR amplified with the following primers: 5′-GAAAGGGCCTATGGGAGATAAAGAGATATTAT-3′ and 5′-GAACTCGAGTTTCTCGATGATGATGAACTTTTGAT-3′ (EhSNX1); 5′-GAACTCTATGGGAGATAAAGAGATATTAT-3′ and 5′-GAACTCGAGTTTCTCGATGATGATGAACTTTTGAT-3′ (EhSNX2). These PCR fragments were digested by Stul and SacI and ligated into Stul- and SacI-double digested psAP2 (Invitrogen, California, USA) according to the manufacturer's protocol.

4.3 Establishment of E. histolytica transformants

The trophozoites of HM-1:IMSS cl6 were transfected with pEhExHA-SNX1, 2, pEhExGFP-SNX1, 2, pEhEx-FLAG-ArpC3, pEhExHA, pEhExGFP, and pEhExFLAG, whereas the trophozoites of G3 strain were transfected with psAP2-SNX1, psAP2-SNX2, and psAP2 by lipofection as previously described (Nozaki et al., 1999). Geneticin was added at a concentration of 1 μg/ml at 24 hr after transfection then gradually until the geneticin concentration reached 10 μg/ml.

4.4 Immunoblot analysis

Approximately 1 × 10^5 trophozoites were harvested in the exponential growth phase, washed twice with phosphate buffer saline (PBS), pH 7.4, and resuspended in 50 μl of lysis buffer (50-mM Tris-HCl, pH 7.5, 150-mM NaCl, 1% Triton X-100, containing 50 μg/ml of E-64, and complete mini). Approximately 20 μg of the total cell lysates were separated on 12% SDS-polyacrylamide gels and subsequently electrotransferred onto nitrocellulose membranes. The membranes were incubated with 5% non-fat dried milk in TBS-T (50-mM Tris-HCl, pH 8.0, 150-mM NaCl and 0.05% Tween-20) for 30 min. The proteins were reacted with primary mouse antibodies specific for HA (with the dilution of 1:1000), myc (1:1000), GFP (1:100), FLAG (1:100) rabbit antiserum against EhVps26 (1:100), EhVps35 (1:500), EhCP-A5 (1:1000), and CS1 (1:1000) at 4°C overnight. After the reaction with the primary antibodies, the membranes were washed with TBS-T three times; they were further reacted with horseradish peroxidase (HRP)-conjugated anti-mouse or anti-rabbit IgG antiserum (1:6000 or 1:8000, respectively) at room temperature for 1 hr. After washing with TBS-T three times, the specific proteins were visualised by chemiluminescence detection using Immobilon Western Chemiluminescent HRP Substrate (Millipore corporation, Massachusetts, USA) according to the manufacturer's protocol.

4.5 Phagosome purification

Paramagnetic Dynabeads of 2.8-μm diameter (catalog number 14203; Invitrogen, California, USA) were incubated with human serum (Sigma-Aldrich) for 16 hr at 4°C, washed, and resuspended in transfection medium (OPTI-MEM I medium [Thermo Fisher, Massachusetts, USA], adjusted to pH 6.8, containing 5-mg/ml L-cysteine and 1-mg/ml ascorbic acid). Approximately 2.4 × 10^7 trophozoites transferred to each well on six-well plates (Corning, New York, USA) and incubated at 35.5°C for 30 min to allow the trophozoites to attach to the surface of the well. After the medium was removed, a 2-ml transfection
medium containing approximately $1 \times 10^7$ human serum-coated beads was added to each well (at the ratio 10 beads per cell). Beads were immediately sedimented on the surface of the amoebae seeded on the well by centrifugation at 100 $\times$ g at room temperature for 5 min. OPTI-MEM was removed and 3 ml of worm BIS was added. The plates were further incubated at 35.5°C for 30 min. After incubation, the medium was removed and 3 ml of cold PBS was added to each well of the plates. The plates were put on ice for 10 min to detach the amoebae, and the amoebae were washed twice with cold PBS. After centrifugation at 800 $\times$ g at 4°C for 3 min, the supernatant was removed and the amoebae were resuspended in 500 $\mu$l of 8 mg/ml dithiobis (succinimidyl propionate; DSP) solution (Thermo Fisher, Massachusetts, USA), containing 0.5 mM of β-glycerophosphate, 0.1 mM of ethylenediaminetetraacetic acid (EDTA), 10-mM sodium fluoride, and 1-mM sodium orthovanadate. The mixture was incubated on the rotator (10 rpm) at 4°C for 30 min. To quench the reaction, 50 $\mu$l of 1 M Tris-HCl, pH 7.5 was added and the mixture was further incubated as above for 10 min. After the amoebae were treated with DSP, they were washed with homogenisation buffer (250-mM sucrose, 3-mMimidazole, in PBS, pH 7.4, and complete mini [Sigma Aldrich]). Cells were mechanically disrupted by applying 25–70 strokes of Dounce homogeniser. The homogenate was centrifuged at 800 $\times$ g at 4°C for 3 min to remove unbroken cells. Bead-containing phagosomes were concentrated from the lysates by magnetic separation on PureProteome Magnetic Stand (Merk). The phagosomes were washed five times with 500 $\mu$l of homogenisation buffer containing protease inhibitors and lysed with 50 $\mu$l of lysis buffer (50-mM Tris-HCl, pH 7.5, 150-mM NaCl, 1% Triton X-100, containing 50 $\mu$g/ml of E-64, and complete mini). For immunoblot analysis, approximately 20 $\mu$l of phagosomes were resuspended in SDS-PAGE sample buffer (0.25-M Tris-HCl, pH 6.8, 8% SDS, 8% 2-mercaptoethanol, 40% Glycerol, 0.004% Bromophenol Blue), boiled for 5 min, and subjected to SDS-PAGE.

4.6 | Lipid overlay assay

Approximately $6 \times 10^6$ cells were harvested and washed with PBS. Approximately 150 $\mu$l of lysis buffer (50-mM Tris-HCl, pH7.5, 15-mM NaCl, containing 1% Triton X-100, 0.05-mg/ml E-64, and complete mini) was added to an approximately 100-$\mu$l bed volume of the pellet. The mixtures were incubated on ice for 30 min and centrifuged at 16,000 $\times$ g for 5 min. The supernatant was saved after centrifugation and used as the total lysate. Nitrocellulose membranes on which various phosphoinositides and other lipids had been spotted (PIP strips: P-6001, Echelon Biosciences, Salt Lake City, USA) were treated with 1% fatty acid-free bovine serum albumin (Sigma-Aldrich) in PBS-T (PBS containing 0.05% Tween 20) for 1 hr at room temperature for blocking. The membranes were incubated with 2 ml of the lipid-binding solution (PBS-T containing 1% fatty acid free bovine serum albumin and complete mini) containing 20-fold diluted amebic lysates for 2 hr at 4°C. After incubation with amoebic lysates, the membranes were washed with PBS-T three times at 4°C. The membranes were then reacted with anti-HA (with the dilution of 1:500), anti-myc mouse monoclonal (1:500), anti-GFP mouse monoclonal (1:100) antibodies, anti-EhVps26 (1:100), and anti-EhVps35 rabbit antiserum (1:500), at 4°C for 3 hr. After the membranes were washed twice with PBS-T at 4°C, they were further reacted with HRP-conjugated anti-mouse or anti-rabbit IgG antiserum (1:6000 or 1:8000, respectively) at 4°C for 1 hr. After washing three times with PBS-T at 4°C, the specific proteins were visualised by chemiluminescence detection using Immobilon Western Chemiluminescent HRP Substrate (Millipore corporation, Massachusetts, USA) according to the manufacturer’s protocol.

4.7 | Quantitative real-time PCR

The levels of EhSNX1 and EhSNX2 gene transcripts were analysed by quantitative real-time PCR. PolyA RNA was extracted, cDNA was prepared, and PCR was performed with cDNA as a template, as previously described (Mitra, Saito-Nakano, Nakada-Tsukui, Sato, & Nozaki, 2007). RNA polymerase II served as an internal control (GenBank accession number, XP_649091; Gilchrist et al., 2006). PCR was performed using the following primer sets: sense primer, 5′-CCTGGTATAGATTAAAAACGAAATTTACTGAAACA-3′ and antisense primer, 5′-GAACCTGAGTTACTTGATGATGATGAACTTTTATAG-3′ for EhSNX1; sense primer 5′-TCGG-TACAATCCACCTTCCTCTGAGATACAATC-3′ and antisense primer 5′-GAACCTGAGTTACAATAGTTACTCTCCATGT-3′ for EhSNX2 and the following cycling parameters: an initial step of denaturation at 95°C for 20 s, followed by 40 cycles of denaturation at 95°C for 3 s, annealing and extension at 60°C for 30 s.

4.8 | Staining of CHO cells

After CHO cells were cultured as described above on 10-cm diameter plastic dishes (IWAKI) for 2 days (before reaching confluence), they were incubated with CellTracker Blue CMAC Dye (Thermo Fisher) at the final concentration of 10 μM at 37°C for 30 min. CHO cells were detached from the surface of the flasks by treating with PBS containing 0.5-mg/ml trypsin and 0.2-mM EDTA at 37°C for 5 min, washed twice with PBS, and resuspended in 600 μl of transfection medium per 3 $\times$ 10^6 CHO cells harvested from one dish.

4.9 | Immunoflorescence assay

Approximately $5 \times 10^3$ E. histolytica trophozoites were incubated with $5 \times 10^4$ Dynabeads M-280 Tosylactivated beads (Invitrogen, California, USA) or $5 \times 10^5$ CHO cells, which had been preainted with CellTracker Blue as described below, in 50-μl BL-S-33 medium in 8-mm round wells on a slide glass at 35.5°C for 15 min. Cells were fixed with 3.7% paraformaldehyde and subsequently permeabilised with 0.2% saponin in PBS containing 1% bovine serum albumin for 10 min each at room temperature. The cells were reacted with anti-HA mouse antibody (with the dilution of 1:1000) or anti-Vps26 rabbit
antibody (1:1000) as previously described (Nakada-Tsukui et al., 2005). After washing with PBS three times, the cells were reacted with Alexa Fluor-488 anti-mouse secondary antibody (1:1000) or Alexa Fluor-568 anti-rabbit secondary antibody (1:1000; Thermo Fisher), respectively. The samples were observed using Carl Zeiss LSM 780 Meta lase-scanning confocal microscope. The resultant images were further analyzed using Zen software (Carl Zeiss, Oberkochen, Germany).

4.10 Live imaging and quantification of GFP-fused EhSNXs

Approximately $7 \times 10^4$ trophozoites of the amoeba transformants transfected with pEhExGFP-SNX1, 2, or pEhExGFP were cultured on 3.5-cm diameter glass bottom dishes in BIS medium under reduced oxygen using AnaeroCult (Merck). After the medium was removed, approximately $7 \times 10^5$ CHO cells were added to the dish at the ratio of 10 CHO cells per amoeba, and the center part of the glass bottom dish was covered by a cover slip. Live imaging was performed on Carl Zeiss LSM780 (Oberkochen, Germany) with default settings on the time series mode. Images were captured by ZEN software (Carl Zeiss). The recruitment of GFP-EhSNX1/2 to phagosomes and trogosomes was estimated by quantitating the fluorescent intensity of a region of interest on the phagosome membrane and the neighboring cytoplasm. The average intensity per pixel of the region of interest was calculated. The ratio of the fluorescent intensity of GFP-EhSNX1/2 on the phagosome membrane against that in the cytosol was calculated and referred as the relative fluorescent signal on the membrane.

4.11 Cross-linking and immunoprecipitation of HA-tagged EhSNXs and native EhVps26

Approximately $1 \times 10^6$ trophozoites of the amoeba transformants transfected with pEhExHA-SNX1, pEhExHA-SNX2, pEhExSNX1-HA, pEhExSNX2-HA, or pEhExHA were cultured on a 10-cm diameter dish in BIS medium with reduced oxygen using AnaeroCult (Merck). CHO cells were added to the dish at the ratio of 10 CHO cells per amoeba, and the dish was incubated at 35.5°C for 30 min. After the medium containing uningested CHO cells was removed, the amoebae were detached from the surface of the dishes by adding cold PBS into the dishes and incubating them on ice for 10 min. After the trophozoites were washed with PBS three times, the cell pellet was cross-linked with DSP as described above. After washing twice with PBS, the cells were lysed with 800 µl of lysis buffer (50-mM Tris-HCl, pH 7.5, 15-mM NaCl, containing 1% Triton X-100, 0.05 mg/ml E-64, and complete mini). After the debris was removed by centrifugation at 16,000 × g at 4°C for 5 min, the lysates were mixed and incubated with 50 µl of protein G Sepharose beads (GE Healthcare, Illinois, USA; 80% slurry) at 4°C for 1 hr. After centrifugation at 800 × g at room temperature for 3 min, the supernatant was transferred to a new 1.5-ml microtube containing either approximately 50 µl of anti-HA monoclonal antibody produced in mouse, clone HA-7, purified immunoglobulin conjugated to agarose beads (Sigma-Aldrich) or 50 µl of protein G Sepharose (GE Healthcare), which was treated with 250 µl of PBS, 2 µl of anti-Vps26 rabbit antiserum for 1 hr at 4°C, was incubated with inversion at 4°C for 3.5 hr. The mixture was centrifuged at 800 × g to separate unbound proteins. The beads were washed three times with 1 ml of lysis buffer. After washing, the beads were resuspended in 180 µl of lysis buffer containing HA-peptide at the final concentration of 0.2 mg/ml and the mixture was incubated at 4°C overnight to elute the bound proteins for HA-EhSNXs or directly boiled with 50 µl of 2x SDS-PAGE sample buffer for EhVps26.

4.12 Quantification of trogocytosis and phagocytosis using image cytometer

Approximately $3 \times 10^5$ trophozoites were incubated in 6 ml of BIS medium containing 10-µM CellTracker Green for 30 min at 35.5°C. CHO cells were stained with 10-µM CellTracker Blue as described above. Approximately $1 \times 10^5$ trophozoites were seeded onto a 3.5-cm diameter glass bottom dish in 2 ml of BIS medium and incubated for 20 min. For trogocytosis measurement, after removing the supernatant, approximately $1 \times 10^5$ CHO cells in 90-µl BIS medium were added onto the 1.0-cm diameter glass central pit of the dish. For phagocytosis measurement, CHO cells were killed by incubating at 55°C for 15 min and added to the pit of the dish. After the pit was covered with a cover glass, the mixture was cultivated at 35.5°C under anaerobic conditions. The images were taken on a Confocal Quantitative Image Cytometer, CQ1 (Yokogawa Electric Corporation, Tokyo, Japan) every 10 min for 80 min. The volume of the ingested CHO cells (blue) was calculated using three-dimensionally reconstituted data. The data shown are the average of the volumes of all trogosomes per amoeba in three wells each. Amoebae were mixed with CHO cells prepared as described above, and images were captured on CQ1. To analyse these data using three-dimensional structured images, CQ1 was set as below. At first, the top and bottom positions of a Z-stack contain almost all phagosomes. The number of slices depends on the distance between layers, which should be less than 4 µm. The images were further analysed to quantify the volume and the fluorescence intensity of the ingested CHO cells using the CellPathfinder high content analysis software from the manufacturer of CQ1.

CONFLICT OF INTEREST

The authors declare no conflict of interest.
