PARACONTROLLED APPROACH TO THE
THREE-DIMENSIONAL STOCHASTIC NONLINEAR WAVE EQUATION
WITH QUADRATIC NONLINEARITY

MASSIMILIANO GUBINELLI, HERBERT KOCH, AND TADAHIRO OH

Abstract. Using ideas from paracontrolled calculus, we prove local well-posedness of a renormalized version of the three-dimensional stochastic nonlinear wave equation with quadratic nonlinearity forced by an additive space-time white noise on a periodic domain. There are two new ingredients as compared to the parabolic setting. (i) In constructing stochastic objects, we have to carefully exploit dispersion at a multilinear level. (ii) We introduce novel random operators and leverage their regularity to overcome the lack of smoothing of usual paradifferential commutators.

1. Introduction

1.1. Singular stochastic nonlinear wave equations. We continue the study of singular stochastic nonlinear wave equations (SNLW) driven by additive space-time white noise initiated in [36]. There we studied the case of the SNLW equation with a polynomial nonlinearity on the two-dimensional torus $T^2 = (\mathbb{R}/2\pi\mathbb{Z})^2$. By introducing a suitable renormalization of the nonlinearity, we proved a local-in-time existence and uniqueness theory. Global solutions on $T^2$ have been obtained in [37] for the defocusing cubic nonlinearity. See also [89] for an analogous global well-posedness result on the Euclidean space $\mathbb{R}^2$. Here, we consider SNLW on the three-dimensional torus $T^3 = (\mathbb{R}/2\pi\mathbb{Z})^3$ starting with the case of quadratic nonlinearity. Our aim is to provide a local well-posedness theory for the equation which formally reads

$$\partial_t^2 u + (1 - \Delta) u = -u^2 + \infty + \xi$$

where $H^s(T^3) = H^s(\mathbb{R}^3) \times H^{s-1}(\mathbb{R}^3)$ and $\xi(x,t)$ denotes a (Gaussian) space-time white noise on $T^3 \times \mathbb{R}_+$ with the space-time covariance given by

$$\mathbb{E}[\xi(x_1, t_1)\xi(x_2, t_2)] = \delta(x_1 - x_2)\delta(t_1 - t_2).$$

The expression $-u^2 + \infty$ denotes the renormalization of the product $u^2$. As we will see below, indeed, solutions to this equation are expected to be distributions of (spatial) regularity below $-\frac{1}{2}$.

We state our main result.

**Theorem 1.1.** Given $\frac{1}{2} < s < \frac{1}{2}$, let $(u_0, u_1) \in H^s(T^3)$. Given $N \in \mathbb{N}$, let $\xi_N = \pi_N \xi$, where $\pi_N$ is the frequency projector onto the spatial frequencies $\{|n| \leq N\}$ defined in [1.17] below. Then, there exists a sequence of time-dependent constants $\{\sigma_N(t)\}_{N \in \mathbb{N}}$ tending to $\infty$ (see [1.20] below) such that, given small $\varepsilon = \varepsilon(s) > 0$, the solution $u_N$ to the following renormalized SNLW:

$$\partial_t^2 u_N + (1 - \Delta) u_N = -u_N^2 + \sigma_N + \xi_N$$

converges to a stochastic process $u \in C([0,T]; H^{-\frac{1}{2} - \varepsilon}(T^3))$ almost surely, where $T = T(\omega)$ is an almost surely positive stopping time.

Furthermore, we will provide a description of the limiting distribution $u$ in terms of the notion of paracontrolled distributions introduced in [34].

Let us comment on the need of the renormalized formulation (1.2). In the context of parabolic stochastic partial differential equations (SPDEs), the need and meaning of renormalization of SPDEs have been intensely studied and much progress has been achieved in recent years, starting with Da Prato and Debussche’s strong solutions approach [23] to the dynamical $\Phi_4^2$ model, continuing with Hairer’s solution of the KPZ equation [30], the subsequent invention of regularity structures [41], and the discovery of alternative approaches such as paracontrolled distributions [34], Kupiainen’s RG approach [57, 58], and the approach of Otto, Weber, and coauthors [78, 55, 77].

On the one hand, the theory of regularity structures [41, 27, 42] has since grown into a complete framework [13, 19, 12, 43] which can deal with a large class of parabolic equations (in the so-called subcritical regime) such as the dynamical sine-Gordon model [17, 20], the generalized KPZ equation used to describe a natural random evolution on the space of paths over a manifold [43], and other interesting models like those related to Abelian gauge theories [82] or some equations...
in the full space \cite{45}. On the other hand, the theory of paracontrolled distributions has revealed itself as an effective method for a restricted class of singular SPDEs \cite{18, 38, 1, 90, 52, 4, 5, 65, 28, 54, 53, 35, 79, 16}. Let us also mention that certain quasilinear parabolic equations can be considered using natural extension of these theories \cite{78, 29, 32}.

Singular SPDEs have been shown to describe large scale behavior of many random dynamical models, including both continuous \cite{49, 48, 50, 84, 30, 51} and discrete ones \cite{64, 17, 83, 61, 46, 62}. This phenomenon has been named weak universality.

Renormalization can be, in first instance, justified in order to obtain non-trivial (i.e. nonlinear) limiting problems. At a deeper level, singular PDEs and the need of their renormalization are tightly linked with the phenomenon of weak universality. These equations are meant to describe the large scale fluctuations of well-behaved smooth random systems and, in this perspective, both the distributional nature of the solution and the renormalization have clear physical meanings; the irregularity of the solutions is the manifestation of the microscopic random fluctuations, while the renormalization is linked to the fine tuning of the parameters needed to allow for nonlinear fluctuations at the macroscopic level. While this discussion is quite informal and general, this picture can be understood rigorously in many specific cases, at least in the parabolic setting.

As far as wave equations are concerned, it has been observed in \cite{81, 2, 69, 70} that SNLW with regularized additive space-time noise converges to a linear equation as the regularization is removed, essentially independently of the kind of (Lipschitz) nonlinearity considered. This hints to the fact that wave equations also need a certain fine tuning of the parameters in order to exhibit singular nonlinear fluctuations.

All the theories we mentioned above are, however, designed to handle parabolic equations and it is not a priori clear how to adapt them to handle dispersive or hyperbolic phenomena.

Schrödinger and wave equations in two and three dimensions with multiplicative spatial white noise have been considered with spectral methods in \cite{25, 24, 39}. The spatial nature of the noise allowed the authors to use techniques similar to the parabolic setting \cite{1}. In our paper \cite{36}, we gave the first example of (non-trivial) weak universality in wave equations by showing that the renormalized SNLW on $\mathbb{T}^2$ describes a particular large scale limit of a random nonlinear wave equation with smooth noise. There, it was shown how, despite the hyperbolic setting, renormalization proceeds in a way quite similar to the parabolic one.

In the present paper, we will also show that, despite the fact that notions such as homogeneity (fundamental in the theory of regularity structures) or Besov-Hölder regularity (similarly fundamental in the theory of paracontrolled distributions in the parabolic setting) are less compelling in the hyperbolic setting, we can set up a paracontrolled analysis of the SNLW equation (1.1) which takes into account multilinear dispersive regularization and renormalization of resonant stochastic terms via the introduction of certain random operators, replacing the commutators standard in the parabolic paracontrolled approach of \cite{34}. Let us note that the control of certain random operators already appeared in the analysis of discrete approximations to the KPZ equation in \cite{38}.

As an application of our results, we can identify the solutions to the SNLW equation (1.1) constructed in Theorem 1.1 as the universal limit of a certain class of random wave equations. Consider the following stochastic nonlinear wave equation on $(\kappa^{-1}\mathbb{T})^3 \times \mathbb{R}_+$:

$$
\begin{aligned}
\partial_t^2 w_\kappa + (1 - \Delta) w_\kappa &= f(w_\kappa) + a^{(0)}_\kappa + a^{(1)}_\kappa w_\kappa + \kappa^2 \eta_\kappa \\
(w_\kappa, \partial_t w_\kappa)_{|t=0} &= (0, 0),
\end{aligned}
$$

(1.3)
where $\kappa > 0$, where $f : \mathbb{R} \to \mathbb{R}$ is an arbitrary bounded $C^3$-function with bounded derivatives and $\eta_\kappa$ is a Gaussian noise which is white in time (for simplicity) and smooth in space with finite range translation-invariant correlations (see (7.1) below for a precise definition). Here, $a_{\kappa}^{(0)}$ and $a_{\kappa}^{(1)}$ are parameters to be chosen later. It is not difficult to show that this equation has global smooth solutions. We think of this equation to be a microscopic model of a given space-time random field $w_\kappa$ living on a large spatial domain $(\kappa^{-1}T)^3$ and subject to a very small random driving force of order $\kappa^2 \ll 1$. For technical reasons we prefer to work in a bounded domain but the reader should think that the equation is set up in the full space and that the parameter $\kappa$ sets the size of the random perturbation. In order to focus on the large scale / long time behavior of the solutions to this equation, we perform an hyperbolic rescaling of the independent variables $(x,t)$ and introduce a new random field $u_\kappa$ given by

$$u_\kappa(x,t) = \kappa^{-2}w_\kappa(\kappa^{-1}x,\kappa^{-1}t), \quad (x,t) \in T^3 \times \mathbb{R}^+.$$  \hspace{1cm} (1.4)

The following theorem gives a precise description of the limiting behavior of $u_\kappa$ as $\kappa \to 0$ and as the parameters $a_{\kappa}^{(0)}, a_{\kappa}^{(1)}$ are tuned in order to have

$$f(w_\kappa) + a_{\kappa}^{(0)} + a_{\kappa}^{(1)}w_\kappa \simeq w_\kappa^2$$

implying that $w_\kappa = 0$ is a solution of the unperturbed dynamics. Accordingly, the initial data in (1.3) are set to zero in order not to interfere with the analysis of the long time effect of the random perturbation.

**Theorem 1.2.** There exists a (time-dependent) choice of the coefficients $a_{\kappa}^{(0)}, a_{\kappa}^{(1)} = O(1)$ and an almost surely positive random time $T$ such that the random field $u_\kappa$ defined in (1.4) converges in probability to a well defined limit $u$ in $C([0,T];H^{-\frac{1}{2}+\varepsilon}(T^3))$ as $\kappa \to 0$. The limiting random field $u$ is (modulo a possible rescaling) a local-in-time solution to the renormalized quadratic SNLW (1.1) with the zero initial data.

In fact, we will choose the coefficient $a_{\kappa}^{(1)}$ depending only on $f$ and $\kappa > 0$, namely it is deterministic and independent of time. See (7.7) below.

**Remark 1.3.** The equation (1.1) indeed corresponds to the stochastic nonlinear Klein-Gordon equation. The same results with inessential modifications also hold for the stochastic nonlinear wave equation, where we replace the left-hand side in (1.1) by $\partial_t^2 u - \Delta u$. In the following, we simply refer to (1.1) as the stochastic nonlinear wave equation.

### 1.2. The Da Prato–Debussche trick.

Let us now describe the strategy which we used in [36, 37] to tackle the renormalization of the two-dimensional SNLW equation:

$$\partial_t^2 u + (1 - \Delta) u = -u^k + \xi, \quad (x,t) \in T^2 \times \mathbb{R}^+,$$

for a generic monomial nonlinearity $u^k$. The first step is to introduce a new variable

$$u = \Psi + v,$$

where $\Psi$ is the stochastic convolution given by

$$\Psi(t) := \mathcal{I}_\xi(t) = \int_0^t \frac{\sin((t-t')\langle\nabla\rangle)}{\langle\nabla\rangle}dW(t').$$

Here, $W$ is a cylindrical Wiener process on $L^2(T^2)$, and $\mathcal{I} = (\partial_t^2 + 1 - \Delta)^{-1}$ is the Duhamel integral operator, corresponding to the forward fundamental solution to the linear wave equation, and $\langle\nabla\rangle$ is the Fourier multiplier operator corresponding to the multiplier $\langle n \rangle = (1 + |n|^2)^{\frac{1}{2}}$. 

By a standard argument, it is easy to see that the stochastic convolution $\Psi$ almost surely has the regularity $C(\mathbb{R}_+; W^{-\varepsilon,\infty}(\mathbb{T}^2))$, $\varepsilon > 0$. Moreover, it can be shown that for each $t > 0$, $\Psi(t) \notin L^2(\mathbb{T}^2)$ almost surely, thus creating an issue in making sense of powers $\Psi^k$ and a fortiori of the full nonlinearity $u^k$. The appropriate renormalization corresponds to replace the powers $\Psi(t)^k$ by the Wick powers $\Psi(t)^k_{\text{Wick}}$ of the stochastic convolution. It then follows that the equation for the residual term $v = u - \Psi$ takes the form:

\[
(\partial_t^2 + 1 - \Delta)v = -\sum_{\ell=0}^k \binom{k}{\ell} \Psi^\ell \cdot v^{k-\ell}.
\]

(1.6)

By viewing $(u_0, u_1, \Psi, \Psi^2, \ldots, \Psi^k)$ as a given enhanced data set, we studied the fixed point problem (1.6) for $v$ via the Strichartz estimates (see Lemma 2.4 below) and we proved that the renormalized SNLW on $\mathbb{T}^2$ is locally well-posed for any integer $k \geq 2$ and is globally well-posed when $k = 3$. See also [75, 72] for a related problem on the deterministic (renormalized) NLW with random initial data.

**Remark 1.4.** (i) In the field of stochastic parabolic PDEs, the decomposition (1.5) is usually referred to as the Da Prato–Debussche trick [22, 23]. Note that such an idea also appears in McKean [63] and Bourgain [11] in the context of (deterministic) dispersive PDEs with random initial data, preceding [22]. See also Burq-Tzvetkov [14].

(ii) While $\Psi$ is not a function, it turns out that the residual part $v$ is a function of positive regularity. Namely, the decomposition (1.5) shows that the solution $u$ "behaves like" the stochastic convolution in the high-frequency regime (or equivalently on small scales).

For our problem on the three-dimensional torus $\mathbb{T}^3$, the Da Prato–Debussche trick does not suffice. Indeed, the stochastic convolution $\Psi$ is less regular in three dimensions: $\Psi \in C(\mathbb{R}_+; W^{-\frac{3}{2} - \varepsilon,\infty}(\mathbb{T}^3))$ almost surely for any $\varepsilon > 0$. See Lemma 3.1 below. This worse behavior also causes the higher Wick powers $\Psi^k$: of $\Psi$ to become less and less regular. Correspondingly, the Cauchy problem with higher powers of the nonlinear term become more and more difficult to study. This is the reason that, in this paper, we limit ourselves to the first non-trivial situation, namely the case $k = 2$ which is already not amenable to be harnessed by the Da Prato–Debussche trick. The main difficulty here is the lack of sufficient regularity for the residual term $v$ in order for the product $\Psi \cdot v$ to be well defined. In the next subsection, we will describe in detail the difficulty and the strategy to overcome this difficulty. In particular we will use ideas from the paracontrolled calculus introduced by the first author (with Imkeller and Perkowski) [34, 18] and rewrite the equation (1.1) in an appropriate form, where the residual term $v$ is further decomposed and analyzed to expose other multilinear stochastic objects of the stochastic convolution $\Psi$ which will be subsequently estimated via probabilistic methods (and via detailed analysis exploiting their multilinear dispersive structures).

For further reference, let us now describe the construction of $\Psi$ in the three-dimensional setting. Let $W$ denote a cylindrical Wiener process on $L^2(\mathbb{T}^3)$. More precisely, by letting $e_n(x) = e^{i n \cdot x}$, $\Lambda = \bigcup_{j=0}^2 \mathbb{Z}^j \times \mathbb{Z}_+ \times \{0\}^{2-j}$, and $\Lambda_0 = \Lambda \cup \{(0, 0, 0)\}$, we have:

\[
e_n(x) = e^{i n \cdot x}, \quad \Lambda = \bigcup_{j=0}^2 \mathbb{Z}^j \times \mathbb{Z}_+ \times \{0\}^{2-j}, \quad \text{and} \quad \Lambda_0 = \Lambda \cup \{(0, 0, 0)\},
\]

(1.7)

1In fact, one may prove local well-posedness of (1.6) on $\mathbb{T}^2$ by Sobolev’s inequality, i.e. without the Strichartz estimates. See [37].

2By convention, we endow $\mathbb{T}^3$ with the normalized Lebesgue measure $(2\pi)^{-3}dx$. 

we have
\[
W(t) = \sum_{n \in \mathbb{Z}^3} \beta_n(t)e_n
\]
\[
= \beta_0(t)e_0 + \sum_{n \in \Lambda} \left[ \sqrt{2} \Re(\beta_n(t)) \cdot \sqrt{2} \cos(n \cdot x) - \sqrt{2} \Im(\beta_n(t)) \cdot \sqrt{2} \sin(n \cdot x) \right],
\]
(1.8)
where \( \{\beta_n\}_{n \in \Lambda_0} \) is a family of mutually independent complex-valued Brownian motions on a fixed probability space \((\Omega, \mathcal{F}, P)\) and \(\beta_{-n} := \bar{\beta}_n\) for \(n \in \Lambda_0\). It is easy to see that \(W\) almost surely lies in \(C^\alpha(\mathbb{R}^+; W^{-\frac{3}{2}} - \varepsilon, \infty(\mathbb{T}^3))\) for any \(\alpha < \frac{1}{2}\) and \(\varepsilon > 0\). We then define the stochastic convolution \(\Psi\) in the three-dimensional setting by
\[
\Psi(t) := I \xi(t) = \sum_{n \in \mathbb{Z}^3} e_n \int_0^t \sin((t - t') \langle n \rangle) \left\langle \beta_n(t') \right\rangle d\beta_n(t').
\]
(1.9)
See Lemma 3.1 below for the regularity property of \(\Psi\).

1.3. The paracontrolled approach. In the field of stochastic parabolic PDEs, there has been a significant progress over the last five years. In [41], Hairer introduced the theory of regularity structures and gave a precise meaning to certain (subcritical) singular stochastic parabolic PDEs, which are classically ill-posed. In particular, he showed that the stochastic quantization equation (SQE) on \(\mathbb{T}^3\):
\[
\partial_t u - \Delta u = -u^3 + \infty \cdot u + \xi
\]
(1.10)
is locally well-posed in an appropriate sense.

In [18], Catellier and Chouk proved an analogous local well-posedness result of SQE (1.10) via the paracontrolled calculus approach of Imkeller, Perkowski, and the first author [34]. This result was extended to global well-posedness on the torus (with a uniform-in-time bound) in a recent work [65] by Mourrat and Weber. More recently, Hofmanová and the first author [35] proved global existence of unique solutions to (1.11) on the Euclidean space \(\mathbb{R}^3\).

In [41, 18], the “solution” \(u\) to (1.10) is constructed as a unique limit of the following smoothed equation:
\[
\partial_t u_\delta - \Delta u_\delta = -u_\delta^3 + C_\delta u_\delta + \xi_\delta,
\]
(1.11)
where \(\xi_\delta = \rho_\delta \ast \xi\) denotes the smoothed noise by a mollifier \(\rho_\delta\). Here, the uniqueness refers to the following: while the diverging constant \(C_\delta\) depends on the choice of the mollifier \(\rho_\delta\), the limit \(u\) is independent of the choice of the mollifier. As it is written, one may wonder if \(u\) actually solves any equation in the end. In fact, one can introduce a decomposition of \(u\) analogous to (1.5) such that the residual terms satisfy a system of PDEs in the pathwise sense.

\[\text{Note that } \{e_0, \sqrt{2} \cos(n \cdot x), \sqrt{2} \sin(n \cdot x) : n \in \Lambda\} \text{ forms an orthonormal basis of } L^2(\mathbb{T}^3) \text{ (endowed with the normalized Lebesgue measure) in the real-valued setting.}\]
\[\text{Here, we take } \beta_0 \text{ to be real-valued. Moreover, we normalized } \beta_n \text{ such that } \text{Var}(\beta_n(t)) = t. \text{ In particular, we have } \text{Var}(\Re \beta_n(t)) = \text{Var}(\Im \beta_n(t)) = \frac{t}{2} \text{ for } n \neq 0.\]
\[\text{In [41], the mollifier } \rho_\delta \text{ is on both spatial and temporal variables, while it is only on spatial variables in [18]. In [57], the author employs a different kind of regularization.}\]
In the following, we briefly describe this decomposition of $u$ in the paracontrolled setting. For this purpose, let us define the stochastic convolution $\mathcal{I}$ by

$$\mathcal{I} = (\partial_t - \Delta)^{-1}\mathcal{C}.$$ 

Here, we adopted Hairer’s convention to denote the stochastic terms by trees; the vertex “.” in $\mathcal{I}$ corresponds to the space-time white noise $\mathcal{C}$, while the edge denotes the Duhamel integral operator $(\partial_t - \Delta)^{-1}$. On $\mathbb{T}^3$, $\mathcal{I}$ has spatial regularity $\frac{1}{2} - \frac{1}{2}$ and hence its powers do not make sense. Denoting the renormalized cubic power “$\mathcal{I}^3$” by $\mathcal{V}$, we define

$$\mathcal{V} = (\partial_t - \Delta)^{-1}\mathcal{C}. \quad (1.12)$$

Thanks to the parabolic smoothing of degree 2, it can be seen that $\mathcal{V}$ has the regularity $\frac{1}{2} - \frac{1}{2} = 3(-\frac{1}{2}) + 2$. See for example [66]. We now write $u$ as

$$u = 1 - \mathcal{V} + v, \quad (1.13)$$

where $v$ is expected to be smoother than $\mathcal{V}$. As mentioned in Remark 1.4, the decomposition $u = 1 + v$ in the Da Prato–Debussche trick postulates $u$ behaves like $\mathcal{I}$ on small scales. This new decomposition (1.13) postulates that the second order fluctuation of $u$ is given by $-\mathcal{V}$. By further splitting $v$ as $v = X + Y$ and introducing more stochastic objects (corresponding to Step (i) in Figure 1), one arrives at a system of PDEs for $X$ and $Y$. Note that the stochastic objects thus introduced satisfy certain regularity properties in an almost sure manner. Hence, by simply viewing them as given deterministic data, we solve the resulting system for $X$ and $Y$ in a purely deterministic manner (Step (ii) in Figure 1).

$$\begin{align*}
(u_0, \xi) \xrightarrow{(i)} & (u_0, 1, V, V, V, V, V) \xrightarrow{(ii)} (X, Y) \mapsto u = 1 - \mathcal{V} + X + Y
\end{align*}$$

**Figure 1.** The decomposition of the ill-posed solution map: $(u_0, \xi) \mapsto u$ into two steps (i) a canonical lift, generating an enhanced data set, and (ii) a deterministic continuous solution map called the Ito-Lyons map. Note that stochastic analysis is needed only in Step (i).

It is in this sense (with (1.13)) that $u$ satisfies the limiting equation (1.10). See a nice exposition in the introduction of [65]. In [31], a similar decomposition of $u$ holds at the level of regularity structures adapted to (1.10).

In the following, we describe a procedure based on a paracontrolled ansatz. This transforms (1.1) into a system of PDEs, which we can solve by standard deterministic tools.

---

6Hereafter, we use $a-$ (and $a+$) to denote $a - \varepsilon$ (and $a + \varepsilon$, respectively) for arbitrarily small $\varepsilon > 0$. If this notation appears in an estimate, then an implicit constant is allowed to depend on $\varepsilon > 0$ (and it usually diverges as $\varepsilon \to 0$).

7In the three-dimensional case, it is known that the “renormalized” cubic power $\mathcal{V}$ does not quite make sense as a distribution due to a logarithmic divergence. Note, however, that $\mathcal{V}$ defined in (1.12) is a well defined function.

8Here, we are oversimplifying the argument. In fact, this decomposition $v = X + Y$ is based on a paracontrolled ansatz, postulating that $(\partial_t - \Delta)v$ is paracontrolled by $\mathcal{V}$. See [18, 65] for further details. We will describe details of this step in studying SNLW. See (1.24) and (1.25).

9The term $\infty \cdot u$ in (1.10) is introduced so that all the terms appearing in the system for $X$ and $Y$ are finite. Here, $\infty$ is interpreted as a limit of the diverging constant $C_3$ in (1.1), which depends on the choice of a mollifier $\rho_3$ (but the limiting distribution $u$ is independent of the choice of the mollifier). See also Remark 1.14 below.
Remark 1.5. The theory of regularity structures introduced by Hairer [41] provides a more complete framework to study singular parabolic equations than the paracontrolled calculus introduced in [34]. However, the theory of regularity structures is more rigid and we do not know how to handle stochastic wave equations in high dimensions at this point. In particular, we don’t know how to lift the Duhamel integral operator $I$.

Moreover, in the parabolic setting, it is easy to predict a regularity of a product. In the theory of regularity structures, this provides an intuition of a resulting homogeneity of a product of two elements in a regularity structure. In the current dispersive setting, we need to exploit a multilinear smoothing property to calculate a regularity of a product of two functions (under the Duhamel integral operator) in a much more careful manner. Hence, any implementation of regularity structures to study dispersive PDEs also needs to incorporate this extra smoothing via an explicit product structure, which seems to be highly non-trivial.

We keep our discussion at a formal level and discuss spatial regularities (= differentiability) of various objects without worrying about precise spatial Sobolev spaces that they belong to. We also use the following “rules”:

- A product of functions of regularities $s_1$ and $s_2$ is defined if $s_1 + s_2 > 0$. When $s_1 > 0$ and $s_1 \geq s_2$, the resulting product has regularity $s_2$.
- A product of stochastic objects (not depending on the unknown) is always well defined, possibly with a renormalization. The product of stochastic objects of regularities $s_1$ and $s_2$ has regularity $\min(s_1, s_2, s_1 + s_2)$.

As in the case of SQE (1.10), we use $\Psi$ to denote the stochastic convolution $\Psi$ for the wave equation defined in (1.9):

$$\Psi = \mathcal{I}(\xi) = \int_0^t \frac{\sin((t - t')\langle\nabla\rangle)}{\langle\nabla\rangle} dW(t').$$  \hspace{1cm} (1.14)

In this context, the vertex “.” in $\Psi$ corresponds to the space-time white noise $\xi$, while the edge denotes the Duhamel integral operator $\mathcal{I}$. Recalling that the spatial regularity $-\frac{3}{2}$ of the space-time white noise $\xi$, the smoothing under $\mathcal{I}$ shows that $\Psi$ has (spatial) regularity $-\frac{1}{2}$. See Lemma 3.1.

Next, we define the second order stochastic term $\mathcal{Y}$ by

$$\mathcal{Y} := \mathcal{I}(\nu) = \int_0^t \frac{\sin((t - t')\langle\nabla\rangle)}{\langle\nabla\rangle} \nu(t') dt',$$  \hspace{1cm} (1.15)

where $\nu$ is the renormalized version of $\Psi^2$; see Proposition 2.1 in [36] and Lemma 3.1 below. This corresponds to the second term in the Picard iteration scheme for (1.1) (with the zero initial data). Note that the Wick power $\nu$ has regularity $-1 = 2(-\frac{1}{2})$. If one proceeds with a “parabolic thinking” then one might expect that $\mathcal{Y}$ has regularity

$$0 = 2(-\frac{1}{2}) + 1,$$  \hspace{1cm} (1.16)

10More precisely, a product of elements in a model space $T$ of a given regularity structure $(A,T,G)$.
11In the remaining part of the paper, we will justify these rules.
12Namely, if we only count the regularity of each of $\Psi$ in $\mathcal{Y}$ and put them together with one degree of smoothing from the Duhamel integral operator $\mathcal{I}$ without taking into account the product structure and the oscillatory nature of the linear wave propagator.
where we gain one derivative from the Duhamel integral operator $I$, in particular from $\langle \nabla \rangle^{-1}$ in (1.15). In fact, we exhibit an extra $\frac{1}{2}$-smoothing for $\mathcal{Y}$ by exploiting the explicit product structure and multilinear dispersion in (1.15).

Before proceeding further, let us introduce some notations. Given $N \in \mathbb{N}$, we define the (spatial) frequency projector $\pi_N$ by

$$
\pi_N u := \sum_{|n| \leq N} \hat{u}(n) e_n.
$$

We then define the truncated stochastic terms $\mathcal{Y}_N$ and $\mathcal{I}_N$ by

$$
\mathcal{I}_N := \pi_N 1_N \quad \text{and} \quad \mathcal{Y}_N := I(\mathcal{V}_N),
$$

where $\mathcal{V}_N$ is the Wick power defined by

$$
\mathcal{V}_N := (1_N)^2 - \sigma_N
$$

with

$$
\sigma_N(t) = \mathbb{E}[(1_N(x,t))^2] = \sum_{|n| \leq N} \int_0^t \left[ \sin((t-t')(\langle n \rangle^2)) \right]^2 dt'.
$$

Note that we have $\mathcal{V} = \lim_{N \to \infty} \mathcal{V}_N$ in $C([0,T];W^{1-\varepsilon,\infty}(\mathbb{T}^3))$ almost surely. See Lemma 3.1 below.

**Proposition 1.6.** Let $T > 0$. Then, $\mathcal{Y}_N$ converges to $\mathcal{Y}$ in $C([0,T];W^{\frac{1}{2}-\varepsilon,\infty}(\mathbb{T}^3)) \cap C^1([0,T];W^{-1-\varepsilon,\infty}(\mathbb{T}^3))$ almost surely for any $\varepsilon > 0$. In particular, we have

$$
\mathcal{Y} \in C([0,T];W^{\frac{1}{2}-\varepsilon,\infty}(\mathbb{T}^3)) \cap C^1([0,T];W^{-1-\varepsilon,\infty}(\mathbb{T}^3))
$$

almost surely for any $\varepsilon > 0$.

This proposition shows an extra $\frac{1}{2}$-smoothing for $\mathcal{Y}$ as compared to (1.16). This extra smoothing results from a multilinear interaction of waves and is a manifestation of dispersion (at a multilinear level), which is a key difference between dispersive and parabolic equations. In proving Proposition 1.6 we combine stochastic tools with multilinear dispersive analysis, in particular, carefully estimating the (nearly) time resonant and time non-resonant contributions. See Remark 3.3. In the following, we will exploit the dispersive nature of our problem in a crucial manner.

We now write $u$ as

$$
u = 1 - \mathcal{Y} + v.
$$

Then, it follows from (1.1) and (1.21) that $v$ satisfies

$$(\partial_t^2 + 1 - \Delta)v = -(v + 1 - \mathcal{Y})^2 + \mathcal{V}
$$

$$
= -(v - \mathcal{Y})^2 - 2v v + 2\mathcal{Y}.
$$

At the second equality, we performed the Wick renormalization: $v^2 \sim v$. The last term $v\mathcal{Y}$ has regularity $-\frac{1}{2}$, inheriting the worse regularity of $\mathcal{V}$. Hence, we expect $v$ to have regularity at most $\frac{1}{2} = (-\frac{1}{2}) + 1$. In particular, the product $v v$ is not well defined since $(\frac{1}{2}) + (-\frac{1}{2}) < 0$.

\[^{13}\text{In our spatially homogeneous setting, the variance } \sigma_N(t) \text{ is independent of } x \in \mathbb{T}^3.\]
In order to overcome this problem, we proceed with the paracontrolled calculus. The main ingredients for the paracontrolled approach in the parabolic setting are (i) a paracontrolled ansatz and (ii) commutator estimates. For the wave equation, however, there seems to be no smoothing for a certain relevant commutator (Remark 1.16) and we need to introduce an alternative argument.

Let us first recall the definition and basic properties of paraproducts introduced by Bony [10]. See Section 2 and [3, 34] for further details. Given $j \in \mathbb{N} \cup \{0\}$, let $P_j$ be the (non-homogeneous) Littlewood-Paley projector onto the (spatial) frequencies $\{n \in \mathbb{Z}^3 : |n| \sim 2^j\}$ such that

$$ f = \sum_{j=0}^{\infty} P_j f. $$

Given two functions $f$ and $g$ on $\mathbb{T}^3$ of regularities $s_1$ and $s_2$, we write the product $fg$ as

$$ fg = f \circ g + f \circ g + f \circ g \quad : = \sum_{j<k-2} P_j f P_k g + \sum_{|j-k| \leq 2} P_j f P_k g + \sum_{k<j-2} P_j f P_k g. \quad (1.22) $$

The first term $f \circ g$ (and the third term $f \circ g$) is called the paraproduct of $g$ by $f$ (the paraproduct of $f$ by $g$, respectively) and it is always well defined as a distribution of regularity $\min(s_2, s_1 + s_2)$. On the other hand, the resonant product $f \circ g$ is well defined in general only if $s_1 + s_2 > 0$. In the following, we also use the notation $f \circ g := f \circ g + f \circ g$.

As in the study of SQE on $\mathbb{T}^3$, we now introduce our paracontrolled ansatz. Namely, we suppose that $v = u - 1 + Y$ can be decomposed as

$$ v = X + Y, \quad (1.23) $$

where $X$ and $Y$ satisfy

$$ (\partial_t^2 + 1 - \Delta) X = -2(X + Y - Y) \circ 1, \quad (1.24) $$

$$ (\partial_t^2 + 1 - \Delta) Y = -(X + Y - Y)^2 - 2(X + Y - Y) \circ 1. \quad (1.25) $$

Furthermore, we postulate that both $X$ and $Y$ have positive regularities $s_1$ and $s_2$, respectively, with $0 < s_1 < s_2$.

**Remark 1.7.** We say that a distribution $f$ is paracontrolled (by a given distribution $g$) if there exists $f'$ such that

$$ f = f' \circ g + h $$

where $h$ is a “smoother” remainder. See Definition 3.6 in [34] for a precise definition. Note, however, that the definition in [34] is given in terms of the Besov-Hölder spaces $C^s = B^s_{\infty, \infty}$ and is not necessarily useful for our dispersive problem. Formally speaking, via the decomposition (1.23) with (1.24) and the regularity assumption $0 < s_1 < s_2$, we are postulating $(\partial_t^2 + 1 - \Delta) v$ is paracontrolled by $1$.

From the first equation (1.24), we see that $X$ has regularity $\frac{1}{2} - = (-\frac{1}{2} - ) + 1$. For now, let us ignore the resonant product $-2(X + Y - Y) \circ 1$ in (1.25) and discuss the regularity of $Y$. Recalling that $Y$ has regularity $\frac{1}{4} -$, we see that the paraproduct $-2(X + Y - Y) \circ 1$ (with regularity $0 -$) as well as $-(X + Y - Y)^2$ in (1.25) hints that $Y$ would have regularity $1 - = (0 - ) + 1$. This is of course provided that we can give a meaning to the resonant product $-2(X + Y - Y) \circ 1$. By postulating that $Y$ has regularity at least $\frac{1}{2} + \varepsilon$ for some $\varepsilon > 0$, we see that the resonant
PARACONTROLLED APPROACH TO 3-d STOCHASTIC NLW

product $Y \otimes 1$ makes sense as a distribution of regularity $s_2 + (-\frac{1}{2}) > 0$ without any problem. Furthermore, we can make sense of the following resonant product:

$$
\mathcal{Y} := Y \otimes 1
$$

as a distribution of regularity $0 = (\frac{1}{2}) + (-\frac{1}{2})$ (without renormalization).

**Proposition 1.8.** Let $T > 0$. Then, $\mathcal{Y}_N := Y_N \otimes 1_N$ converges to $\mathcal{Y}$ in $C([0, T]; W^{-\varepsilon, \infty}(\mathbb{T}^3))$ almost surely for any $\varepsilon > 0$. In particular, we have

$$
\mathcal{Y} \in C([0, T]; W^{-\varepsilon, \infty}(\mathbb{T}^3))
$$

almost surely for any $\varepsilon > 0$.

If one simply writes out $\mathcal{Y}$, then there seems to be a logarithmically divergent contribution (see (1.3)). We can, however, exploit dispersion at a multilinear level as in Proposition 1.6 and show that $\mathcal{Y}$ is indeed a well defined distribution.

Hence, it remains to give a meaning to the resonant product $X \otimes 1$. Writing the equation (1.24) in the Duhamel formulation, we have

$$
X = S(t)(X_0, X_1) - 2I((X + Y - Y) \otimes 1),
$$

where $(X, \partial_tX)|_{t=0} = (X_0, X_1) \in \mathcal{H}^{s_1}(\mathbb{T}^3)$ and $S(t)$ is the propagator for the linear wave equation defined by

$$
S(t)(u_0, u_1) := \cos(t\langle \nabla \rangle) u_0 + \frac{\sin(t\langle \nabla \rangle)}{\langle \nabla \rangle} u_1.
$$

We need to make sense of the resonant product between $\otimes 1$ and each of the terms on the right-hand side of (1.27). The next lemma establishes a regularity property of the resonant product:

$$
Z = Z(X_0, X_1) := (S(t)(X_0, X_1)) \otimes 1.
$$

**Lemma 1.9.** Given $s_1 > 0$, let $(X_0, X_1) \in \mathcal{H}^{s_1}(\mathbb{T}^3)$. Then, given $T > 0$ and $\varepsilon > 0$,

$$
Z_N := (S(t)(X_0, X_1)) \otimes 1_N
$$

converges to $Z = (S(t)(X_0, X_1)) \otimes 1$ in $C([0, T]; H^{s_1 - \frac{1}{2} - \varepsilon}(\mathbb{T}^3))$ almost surely. In particular, we have

$$
Z = (S(t)(X_0, X_1)) \otimes 1 \in C([0, T]; H^{s_1 - \frac{1}{2} - \varepsilon}(\mathbb{T}^3))
$$

almost surely for any $\varepsilon > 0$.

See Section 5 for the proof.

**Remark 1.10.** While the proof of Lemma 1.9 is a straightforward application of the Wiener chaos estimate (Lemma 2.5), we point out that the set of probability one on which the conclusion of Lemma 1.9 holds depends on the choice of deterministic initial data $(X_0, X_1) \in \mathcal{H}^{s_1}(\mathbb{T}^3)$. This is analogous to the situation for the recent study of nonlinear dispersive PDEs with randomized initial data [42, 19, 6, 7, 70, 73, 74, 8], where a set of probability one for local-in-time or global-in-time well-posedness depends on the choice of deterministic initial data (to which a randomization is applied). See [13] for a further discussion.
The main difficulty arises in making sense of the resonant product of the second term on the right-hand side of (1.27) and \( t \). In the parabolic setting, it is at this step where one would introduce commutators in (1.27) and exploit their smoothing properties. For our dispersive problem, however, such an argument does not seem to work. See Remark 1.16 below. This is where our discussion diverges from the parabolic case.

The main idea is to study the following paracontrolled operator \( \mathcal{I}_\ominus \) and exhibit some smoothing property. Given a function \( w \in C(\mathbb{R}_+; H^{s_1}(\mathbb{T}^3)) \) with \( 0 < s_1 < \frac{1}{2} \), define

\[
\mathcal{I}_\ominus(w)(t) := \mathcal{I}(w \odot 1)(t) = \sum_{j < k - 2} b_j w \cdot P_k
\]

\[
= \sum_{n \in \mathbb{Z}^3} e_n \sum_{n = n_1 + n_2}^{t \leq |n_1| < |n_2|} \int_0^t \sin((t - t')(n)) \hat{w}(n_1, t') \hat{\gamma}(n_2, t') dt'.
\] (1.28)

Here, \( |n_1| \ll |n_2| \) signifies the paraproduct \( \odot \) in the definition of \( \mathcal{I}_\ominus \). In the following, we decompose the paracontrolled operator \( \mathcal{I}_\ominus \) into two pieces and study them separately.

Fix small \( \theta > 0 \). Denoting by \( n_1 \) and \( n_2 \) the spatial frequencies of \( w \) and \( 1 \) as in (1.28), we further define \( \mathcal{I}^{(1)}_\ominus \) and \( \mathcal{I}^{(2)}_\ominus \) as the restrictions of \( \mathcal{I}_\ominus \) onto \( \{ |n_1| \gtrsim |n_2|^\theta \} \) and \( \{ |n_1| \ll |n_2|^\theta \} \). More concretely, we set

\[
\mathcal{I}^{(1)}_\ominus(w)(t) := \sum_{n \in \mathbb{Z}^3} e_n \sum_{|n_1| \ll |n_2|^\theta} \int_0^t \sin((t - t')(n)) \hat{w}(n_1, t') \hat{\gamma}(n_2, t') dt'.
\] (1.29)

and \( \mathcal{I}^{(2)}_\ominus(w) := \mathcal{I}_\ominus(w) - \mathcal{I}^{(1)}_\ominus(w) \). As for the first paracontrolled operator \( \mathcal{I}^{(1)}_\ominus \), thanks to the lower bound \( |n_1| \gtrsim |n_2|^\theta \) and the positive regularity of \( w \), we exhibit some smoothing property such that the resonant product \( \mathcal{I}^{(1)}_\ominus(X + Y + \gamma) \odot 1 \) is well defined. See Lemma 5.1 and Corollary 5.2.

Next, we discuss the second paracontrolled operator \( \mathcal{I}^{(2)}_\ominus \). Our goal is to make sense of the resonant product \( \mathcal{I}^{(2)}_\ominus(w) \odot 1 \) for \( w \) with spatial regularity \( \frac{1}{2} \). Unlike \( \mathcal{I}^{(1)}_\ominus \), the operator \( \mathcal{I}^{(2)}_\ominus \) does not seem to possess a smoothing property and thus we need to directly study the operator \( \mathcal{I}^{(2)}_\ominus \) defined by

\[
\mathcal{I}^{(2)}_{\ominus, \ominus}(w)(t) := \mathcal{I}^{(2)}_\ominus(w) \odot 1(t)
\]

\[
= \sum_{n \in \mathbb{Z}^3} e_n \int_0^t \sum_{n_1 \in \mathbb{Z}^3} \hat{w}(n_1, t') \mathcal{A}_{n, n_1}(t, t') dt',
\] (1.30)

where \( \mathcal{A}_{n, n_1}(t, t') \) is given by

\[
\mathcal{A}_{n, n_1}(t, t') = 1_{[0, t]}(t') \sum_{n - n_1 = n_2, n_2 \ll |n_2|^\theta} \sin((t - t')(n_1 + n_2)) \hat{\gamma}(n_2, t') \hat{\gamma}(n_3, t).
\] (1.31)

Here, the condition \( |n_1 + n_2| \sim |n_3| \) is used to denote the spectral multiplier corresponding to the resonant product \( \odot \) in (1.30). See (5.7) for a more precise definition.

\(^{14}\) For simplicity of the presentation, we use the less precise definitions of paracontrolled operators in the remaining part of this introduction. See (5.2), (5.3), and (5.7) for the precise definitions of the paracontrolled operators \( \mathcal{I}^{(1)}_\ominus \) and \( \mathcal{I}^{(2)}_{\ominus, \ominus} \).
Given \(n \in \mathbb{Z}^3\) and \(0 \leq t_2 \leq t_1\), define \(\sigma_n(t_1, t_2)\) by

\[
\sigma_n(t_1, t_2) := \mathbb{E}\left[\tilde{\tau}(t_1) \tilde{\eta}(-n, t_2)\right] = \int_0^{t_2} \frac{\sin((t_1 - t')(n))}{\langle n \rangle} \cos((t_1 - t')(n)) \sin((t_2 - t')(n)) dt'
\]

\[
= \frac{\cos((t_1 - t_2)(n))}{2 \langle n \rangle^2} t_2 + \frac{\sin((t_1 - t_2)(n))}{4 \langle n \rangle^3} - \frac{\sin((t_1 + t_2)(n))}{4 \langle n \rangle^3}.
\tag{1.32}
\]

Recall from the definition (1.14) (also see (1.9)) that \(\tilde{\tau}(n_2, t')\) and \(\tilde{\eta}(n_3, t)\) are uncorrelated unless \(n_2 + n_3 = 0\), i.e. \(n = n_1\). This leads to the following decomposition of \(\mathcal{A}_{n,n_1}\):

\[
\mathcal{A}_{n,n_1}(t, t') = \mathbb{1}_{[0,t]}(t') \sum_{n-n_1=n_2+n_3} \frac{\sin((t - t')(n_1 + n_2))}{\langle n_1 + n_2 \rangle} \times \left(\tilde{\tau}(n_2, t') \tilde{\eta}(n_3, t) - \mathbb{1}_{n_2+n_3=0} \cdot \sigma_{n_2}(t, t')\right)
\]

\[
+ \mathbb{1}_{[0,t]}(t') \cdot \mathbb{1}_{n_1=n} \sum_{n_2 \in \mathbb{Z}^3} \frac{\sin((t - t')(n + n_2))}{\langle n + n_2 \rangle} \sigma_{n_2}(t, t')
\]

\[
=: \mathcal{A}_{n,n_1}^{(1)}(t, t') + \mathcal{A}_{n,n_1}^{(2)}(t, t').
\tag{1.33}
\]

The second term \(\mathcal{A}_{n,n_1}^{(2)}\) is a (deterministic) “counter term” for the contribution in (1.31) from \(n_2 + n_3 = 0\). For this term, the condition \(|n_1 + n_2| \sim |n_3|\) reduces to \(|n_1 + n_2| \sim |n_2|\) which is automatically satisfied under \(|n| \ll |n_2|^\theta\) for small \(\theta > 0\). See (4.11) and (4.12) below.

In view of (1.32), the sum in \(n_2\) for the second term \(\mathcal{A}_{n,n_1}^{(2)}\) is not absolutely convergent. Nonetheless, by exploiting dispersion, we show the following boundedness property of the paracontrolled operator \(\mathcal{I}_{\otimes,\otimes}\) defined in (1.30). Given Banach spaces \(B_1\) and \(B_2\), we use \(\mathcal{L}(B_1; B_2)\) to denote the space of bounded linear operators from \(B_1\) to \(B_2\).

**Proposition 1.11.** Let \(s_2 < 1\) and \(T > 0\). Then, there exists small \(\theta = \theta(s_2) > 0\) and \(\varepsilon > 0\) such that the paracontrolled operator \(\mathcal{I}_{\otimes,\otimes}\) defined in (1.30) belongs to the class:

\[
\mathcal{L}_1 = \mathcal{L}(C([0,T]; L^2(\mathbb{T}^3))) \cap C^1([0,T]; H^{-1-\varepsilon}(\mathbb{T}^3))) \cap C([0,T]; H^{s_2-1}(\mathbb{T}^3))),
\tag{1.34}
\]

almost surely. Moreover, if we define the paracontrolled operator \(\mathcal{I}^N_{\otimes,\otimes}\), \(N \in \mathbb{N}\), by replacing \(\mathbb{1}\) in (1.30) and (1.31) with the truncated stochastic convolution \(\mathbb{1}_N\) in (1.35), then the truncated paracontrolled operators \(\mathcal{I}^N_{\otimes,\otimes}\) converge almost surely to \(\mathcal{I}_{\otimes,\otimes}\) in \(\mathcal{L}_1\).

As in the proofs of Propositions 1.6 and 1.8, dispersion plays an essential role in establishing the regularity property of the paracontrolled operator \(\mathcal{I}_{\otimes,\otimes}\). See Section 5 for the proof.

Putting all together, we obtain the following system of PDEs for \(X\) and \(Y\):

\[
\begin{align*}
(\partial_t^2 + 1 - \Delta)X &= -2(X + Y - \gamma) \otimes 1, \\
(\partial_t^2 + 1 - \Delta)Y &= -(X + Y - \gamma)^2 - 2(X + Y - \gamma) \otimes 1 \\
&- 2Y \otimes 1 + 2\gamma - 2Z \\
&+ 4\mathcal{I}_{\otimes}^{(1)}(X + Y - \gamma) \otimes 1 + 4\mathcal{I}_{\otimes,\otimes}(X + Y - \gamma),
\end{align*}
\tag{1.35}
\]

\((X, \partial_t X, Y, \partial_t Y)|_{t=0} = (X_0, X_1, Y_0, Y_1)\).
Let $s_1 < \frac{1}{2}$ and fix a pair of deterministic functions $(X_0, X_1)$ in $\mathcal{H}^{s_1}(\mathbb{T}^3)$. The stochastic terms and operator appearing in the system (1.35) are

$$t, \ Y, \ \mathcal{Y}, \ Z = Z(X_0, X_1), \text{ and } \mathcal{I}_{\otimes, \otimes}, \quad (1.36)$$

In Lemma 3.1 and Propositions 1.6 and 1.8, we study the regularity properties of $t$, $Y$, and $\mathcal{Y}$, and show that each of these terms belongs almost surely to $C(\mathbb{R}_+; W^{s, \infty}(\mathbb{T}^3))$ with the regularity $s$ shown in Table 1. In Lemma 1.9, we prove that $Z \in C(\mathbb{R}_+; H^{s}(\mathbb{T}^3))$ almost surely for $s < s_1 - \frac{1}{2}$.

In Proposition 1.11, we establish the almost sure boundedness property of the paracontrolled operator $\mathcal{I}_{\otimes, \otimes}$ in an appropriate space. We summarize these regularity properties in Table 1.

| $s$ | $t$ | $Y$ | $\mathcal{Y}$ | $Z$ | $\mathcal{I}_{\otimes, \otimes}$ |
|-----|-----|-----|-------|-----|------------------|
| $\frac{1}{2} - \varepsilon$ | $\frac{1}{2} - \varepsilon$ | $-\varepsilon$ | $s_1 - \frac{1}{2} - \varepsilon$ | $\mathcal{L}_1$ in (1.34) |

**Table 1.** The list of relevant stochastic terms with their regularities.

In Lemma 5.1 and Corollary 5.2, we also study the regularity property of the paracontrolled operator $\mathcal{Y}_{\otimes}$.

We now state our main result on local well-posedness of the system (1.35), viewing the terms and operators in (1.36) as predefined deterministic data with certain regularity properties.

**Theorem 1.12.** Let $\frac{1}{4} < s_1 < \frac{1}{2} < s_2 \leq s_1 + \frac{1}{2}$. There exist small $\theta = \theta(s_2) > 0$ and $\varepsilon = \varepsilon(s_1, s_2, \theta) > 0$ such that if

- $t$, $Y$, and $\mathcal{Y}$, are distributions belonging to $C(\mathbb{R}_+; W^{s, \infty}(\mathbb{T}^3))$ for $s$ as in Table 1. Moreover, we assume that
  $$Y \in C^1(\mathbb{R}_+; W^{-1-\varepsilon, \infty}(\mathbb{T}^3)),$$
  $$Z \text{ is a distribution belonging to } C(\mathbb{R}_+; H^{s_1-\frac{1}{2}-\varepsilon}(\mathbb{T}^3)),$$
  $$\mathcal{I}_{\otimes, \otimes} \text{ belongs to the class } \mathcal{L}_1 \text{ in (1.34)},$$

then the system (1.35) is locally well-posed in $\mathcal{H}^{s_1}(\mathbb{T}^3) \times \mathcal{H}^{s_2}(\mathbb{T}^3)$. More precisely, given any $(X_0, X_1, Y_0, Y_1) \in \mathcal{H}^{s_1}(\mathbb{T}^3) \times \mathcal{H}^{s_2}(\mathbb{T}^3)$, there exists $T > 0$ such that there exists a unique solution $(X, Y)$ to the system (1.35) on $[0, T]$ in the class

$$Z^{s_1, s_2} = X^{s_1}_T \times Y^{s_2}_T \subset C([0, T]; H^{s_1}(\mathbb{T}^3) \times H^{s_2}(\mathbb{T}^3)) \cap C^1([0, T]; H^{s_1-1}(\mathbb{T}^3) \times H^{s_2-1}(\mathbb{T}^3)),$$

depending continuously on the enhanced data set:

$$\Xi = (X_0, X_1, Y_0, Y_1, t, Y, \mathcal{Y}, Z, \mathcal{I}_{\otimes, \otimes}) \quad (1.37)$$

in the class:

$$X^{s_1, s_2, \varepsilon}_T = H^{s_1}(\mathbb{T}^3) \times H^{s_2}(\mathbb{T}^3) \times C([0, T]; W^{-\frac{1}{4}-\varepsilon, \infty}(\mathbb{T}^3)) \times (C([0, T]; W^{\frac{1}{2}-\varepsilon, \infty}(\mathbb{T}^3)) \cap C^1([0, T]; W^{-1-\varepsilon, \infty}(\mathbb{T}^3))) \quad (1.38)$$

$$\times C([0, T]; W^{-\varepsilon, \infty}(\mathbb{T}^3)) \times C([0, T]; H^{1-\frac{1}{2}-\varepsilon}(\mathbb{T}^3)) \times \mathcal{L}_1.$$

Here, $X^{s_1}_T$ and $Y^{s_2}_T$ are the energy spaces at the regularities $s_1$ and $s_2$ intersected with appropriate Strichartz spaces. See (6.1) below.
Theorem 1.12 states local well-posedness of the system (1.35) when we view the enhanced data set \( N, Y, \gamma, Z, \) and \( \mathcal{O}_{\oplus} \) as given deterministic distributions or operator. As such, the proof of Theorem 1.12 is entirely deterministic. By writing (1.35) in the Duhamel formulation
\[
X(t) = \Phi_1(X, Y)(t)
\]
\[
:= S(t)(X_0, X_1) - 2 \int_0^t \sin((t-t')(\nabla)) \left[ (X + Y) \otimes 1 \right] (t') dt',
\]
\[
Y(t) = \Phi_2(X, Y)(t)
\]
\[
:= S(t)(Y_0, Y_1) - \int_0^t \sin((t-t')(\nabla)) \left[ (X + Y) \otimes 1 \right] (t') dt',
\]
we show that the map \( \Phi = (\Phi_1, \Phi_2) \) is a contraction on a closed ball in \( Z_T^{s_1,s_2} \) for sufficiently small \( T > 0 \) which depends only on the \( X^{s_1,s_2,\varepsilon} \)-norm of the enhanced data set \( \Sigma \) in (1.37). The main tools are (i) the Strichartz estimates for the wave equations (Lemma 2.4) and (ii) the paraproduct estimates (Lemma 2.1). See Section 6 for details.

Finally, let us discuss the consequence of Theorem 1.12 on the original SNLW (1.1).

Proof of Theorem 1.12. Let \( \frac{1}{4} < s < \frac{1}{2} \). Given \( (u_0, u_1) \in \mathcal{H}^s(\mathbb{T}^3) \), let \( (X_0, X_1, Y_0, Y_1) = (u_0, u_1, 0, 0) \). For each \( N \in \mathbb{N} \), we construct the enhanced data set associated with the truncated noise \( \xi_N = \pi_N \xi \):
\[
\Xi_N = (u_0, u_1, 0, 1_N, Y_N, \gamma, Z_N, \mathcal{O}_{\oplus}).
\]
Here, \( 1_N, Y_N, \gamma, Z_N \), and \( \mathcal{O}_{\oplus} \) are as in (1.18) and Propositions 1.8 and 1.11 while we set \( Z_N = Z_N(u_0, u_1) = S(t)(u_0, u_1) \otimes 1_N \). Let \( (X_N, Y_N) \) be the unique local-in-time solution to the system (1.35) with the enhanced data set \( \Xi_N \) and define \( u_N \) by
\[
u_N = 1_N - Y_N + X_N + Y_N.
\]
Then, by reversing the discussion above with (1.19), we see that \( u_N \) satisfies the renormalized SNLW (1.2) provided \( \sigma_N \) is chosen as in (1.20).

From Lemma 3.1, Propositions 1.6, 1.8, Lemma 1.9, Corollary 5.2, and Proposition 1.11 we see that \( \Xi_N \) converges almost surely to
\[
\Xi = (u_0, u_1, 0, 1, \gamma, \mathcal{O}, S(t)(u_0, u_1) \otimes 1, \mathcal{O}_{\oplus})
\]
in the \( X^{s_1,\frac{1}{2}+\varepsilon,\varepsilon}_1 \)-topology for some small \( \varepsilon > 0 \). Then, the (pathwise) continuous dependence of the solution map for the system (1.35) on the enhanced data set in \( X^{s_1,\frac{1}{2}+\varepsilon,\varepsilon}_1 \) implies that

- the (random) local existence time \( T = T(\omega) \) depicted in Theorem 1.12 can be chosen uniformly for \( \{(X_N, Y_N)\}_{N \in \mathbb{N}} \) and \( (X, Y) \). Here, \( (X, Y) \) is the unique solution to (1.35) with the enhanced data \( \Sigma \) in (1.41).
- the solution \( u_N \) to the renormalized SNLW (1.2) defined in (1.40) converges almost surely to \( u \) in \( C([0, T]; H^{-\frac{1}{2}+\varepsilon}(\mathbb{T}^3)) \), where \( u \) is given by
\[
u = 1 - Y + X + Y.
\]
This proves Theorem 1.1 under the condition that \( \sigma_N \) is chosen as described in (1.20). \( \square \)
Remark 1.13. As we pointed out in Remark 1.10, the set \( \Sigma \) of probability one on which Theorem 1.1 holds depends on the choice of (deterministic) initial data \((u_0, u_1) \in H^s(T^3)\) due to Lemma 1.9. If we assume a slightly higher regularity, namely, if we work with \((u_0, u_1) \in H^s(T^3)\) for some \( s > \frac{1}{2} \), we can choose the set \( \Sigma \) of probability one, independent of \((u_0, u_1) \in H^s(T^3)\), by simply setting \((X_0, X_1, Y_0, Y_1) = (0, 0, u_0, u_1)\), which avoids the use of Lemma 1.9.

Remark 1.14. Given \( \rho \in L^1(\mathbb{R}^3) \) with \( \int_{\mathbb{R}^3} \rho(x)dx = 1 \) and \( \text{supp} \rho \subset (-\frac{1}{2}, \frac{1}{2})^3 \), we define a smooth mollifier \( \rho_\delta, 0 < \delta \leq 1 \), by setting
\[
\rho_\delta(x) = \delta^{-3} \rho(\delta^{-1}x).
\]

We also say that such \( \rho \) is a mollification kernel. Then, the same argument leading to Theorem 1.1 can be used to prove the following convergence and uniqueness statement. See [41, 18]. Given \( \frac{1}{4} < s < \frac{1}{2}, \) let \((u_0, u_1) \in H^s(T^3)\). Let \( \xi_\delta = \rho_\delta \ast \xi \) be the smoothed noise by a smooth mollifier \( \rho_\delta \).

Then, for any \( 0 < \delta \leq 1 \), there exists \( C_\delta = C_\delta(t, \rho) \) such that the solution \( u_\delta \) to the following smoothed SNLW:
\[
\begin{align*}
\partial_t^2 u_\delta + (1 - \Delta) u_\delta &= -u_\delta^2 + C_\delta + \xi_\delta \\
(u_\delta, \partial_t u_\delta)|_{t=0} &= (u_0, u_1)
\end{align*}
\]
converges in probability to some distribution \( u \) in \( C([0, T]; H^{-\frac{1}{2}-\epsilon}(T^3)) \) for any \( \epsilon > 0 \), where \( T = T(\omega) \) is an almost surely positive stopping time, independent of \( 0 < \delta \leq 1 \). Here, we have \( C_\delta(t, \rho) = C_0 \frac{1}{\delta} + C(t, \rho) \), where \( C_0 \) is a universal constant and \( C(t, \rho) \) is a finite constant.

Moreover, the limit \( u \) is unique in the sense that it is independent of the choice of the mollification kernel \( \rho \).

Let us complete this section by some additional observations.

Remark 1.15. (i) In making sense of the resonant product \( X \otimes 1 \), we substituted the Duhamel formula for \( X \) as in (1.27). This is analogous to the treatment of SQE (1.10); see [65]. Note that such an iteration of the (part of) Duhamel formula already appears in in the study of the stochastic KdV equation with an additive (almost) white noise. See [33, 71].

(ii) Unlike the parabolic setting, we need to assume higher regularity for initial data than the stochastic convolution. This is due to the lack of smoothing in our dispersive problem. If initial data is random (independent of the additive space-time white noise), we may take it to be of low regularity.

(iii) In Proposition 1.11, we assumed one time differentiability of an input function for the paracontrolled operator \( J \otimes \odot \). This smoothness in time allows us to exploit the time oscillation by integration by parts. See (5.18) below. On the one hand, we may prove an analogous boundedness result by assuming less time regularity of an input function. On the other hand, it seems that we do need to assume some time regularity of an input function. This necessity for smoothness in time is analogous to the parabolic setting, but for a different reason in the parabolic setting; see [41, 18, 65].

Remark 1.16 (On commutators). As we mentioned above, commutators play an important role in applying the paracontrolled calculus in the parabolic setting. If we were to follow the argument for SQE presented in [65], then we would write (1.27) as
\[
X = S(t)(X_0, X_1) - 2I((X + Y + \gamma) \otimes 1)
= S(t)(X_0, X_1) - 2(X + Y + \gamma) \otimes I(1) + \text{com}_1.
\]
(1.43)
Here, the commutator \( \text{com}_1 \) denotes the commutator of the paraproduct \( \otimes \) and the Duhamel integral operator \( I = (\partial_t^2 + 1 - \Delta)^{-1} \).

In the case of SQE (1.10) on \( \mathbb{T}^3 \), it was crucial that the commutator of the paraproduct \( \otimes \) and the Duhamel integral operator \( (\partial_t - \Delta)^{-1} \) for the heat equation enjoyed some smoothing property, which resulted from the smoothing property of the commutator \( [e^{t\Delta}, \otimes] \) between the linear heat semigroup \( e^{t\Delta} \) and the paraproduct \( \otimes \) (see Lemma 2.5 in [18] and Proposition A.16 in [65]). Unfortunately, in our dispersive setting, the commutator \( \text{com}_1 \) does not seem to provide any smoothing. We point out that if the identity [1.43] were to hold with a smoother commutator, then the rest would follow as in the parabolic setting [65] (and in particular, there would no need to introduce paracontrolled operators). Namely, by defining

\[
[\otimes, \otimes](f, g, h) = (f \otimes g) \otimes h - f(g \otimes h),
\]

we can write \( X \otimes 1 \) as

\[
X \otimes 1 = S(t)(X_0, X_1) - 2(X + Y + \gamma)(I(t) \otimes 1) + \text{com}_1 \otimes 1 + \text{com}_2,
\]

where \( \text{com}_2 \) is given by \( \text{com}_2 = [\otimes, \otimes](X + Y + \gamma, I(t), t) \). Note that \( \text{com}_2 \) is a well-defined distribution thanks to the smoothing property of \( [\otimes, \otimes] \). See Lemma 2.4 in [34] and Proposition A.9 in [65].

Let us now consider the first commutator \( \text{com}_1 \). Given an operator \( T \), let

\[
[T, \otimes](f, g) = T(f \otimes g) - f \otimes (Tg).
\]

Then, by setting \( S = \langle \nabla \rangle I = \langle \nabla \rangle (\partial_t^2 + 1 - \Delta)^{-1} \), we have

\[
[I, \otimes](f, g) = S \circ [\langle \nabla \rangle^{-1}, \otimes] (f, g) + [S, \otimes](f, \langle \nabla \rangle^{-1} g).
\]

It is easy to see that the first commutator \( [\langle \nabla \rangle^{-1}, \otimes] \) enjoys certain smoothing\(^{15}\). On the other hand, if we were to exhibit smoothing for the second commutator \( [S, \otimes] \) as in the parabolic setting, we would need to study the smoothing property of the commutator \( [\sin(t \langle \nabla \rangle), \otimes] \). Unfortunately, there seems to be no smoothing for this commutator in general\(^{16}\) which prevents us from working with commutators for our dispersive problem. By introducing the paracontrolled operators, we indeed exhibit smoothing under the commutator \( [S, \otimes] \) (and hence under \( [I, \otimes] \)) in a probabilistic manner with a specific second input function, i.e., \( g = 1 \). See Proposition 1.11. This is in sharp contrast with the parabolic setting, where a smoothing can be shown for \( [e^{t\Delta}, \otimes] \) in a deterministic manner (without specifying the second input function either).

Lastly, we point out that our approach via paracontrolled operators also works in the parabolic setting. In particular, in place of using commutators, we can directly study relevant paracontrolled operators to prove local well-posedness of SQE (1.10) on \( \mathbb{T}^3 \).

---

\(^{15}\)If \( f \) and \( g \) have regularities \( 0 < s_1 < 1 \) and \( s_2 < 0 \) with \( s_1 + s_2 < 0 \), then each of \( \langle \nabla \rangle^{-1} (f \otimes g) \) and \( f \otimes (\langle \nabla \rangle^{-1} g) \) has regularity \( s_2 + 1 \). On the other hand, the commutator \( \langle \langle \nabla \rangle^{-1}, \otimes \rangle \langle f, g \rangle \) has regularity \( s_1 + s_2 + 1 \). Roughly speaking, this fact follows from the following observation; given \( n, n_1, n_2 \in \mathbb{Z}^3 \) with \( n = n_1 + n_2 \), we have

\[
\left| \frac{1}{\langle n \rangle} - \frac{1}{\langle n_2 \rangle} \right| = \frac{\langle n_2 \rangle - \langle n_1 \rangle}{\langle n \rangle \langle n_2 \rangle} \lesssim \frac{\langle n_1 \rangle}{\langle n_1 \rangle \langle n_2 \rangle}.
\]

In particular, when \( |n_1| \ll |n_2| \sim |n| \) and the first function \( f \) has positive regularity, this observation provides smoothing.

\(^{16}\)Under \( |n_1| \ll |n_2| \), there is no smoothing for \( \sin(t(n_1 + n_2)) \) (or \( \sin(tn_2) \)).
2. Notations and basic lemmas

2.1. Sobolev spaces and Besov spaces. Let $s \in \mathbb{R}$ and $1 \leq p \leq \infty$. We define the $L^2$-based Sobolev space $H^s(\mathbb{T}^3)$ by the norm:

$$\|f\|_{H^s} = \|\langle n \rangle^s \hat{f}(n)\|_{\ell^2_n},$$

and set $\mathcal{H}^s(\mathbb{T}^3)$ to be

$$\mathcal{H}^s(\mathbb{T}^3) = H^s(\mathbb{T}^3) \times H^{s-1}(\mathbb{T}^3).$$

We also define the $L^p$-based Sobolev space $W^{s,p}(\mathbb{T}^3)$ by the norm:

$$\|f\|_{W^{s,p}} = \|F^{-1}(\langle n \rangle^s \hat{f}(n))\|_{L^p},$$

with the standard modification when $p = \infty$. When $p = 2$, we have $H^s(\mathbb{T}^3) = W^{s,2}(\mathbb{T}^3)$.

Let $\phi: \mathbb{R} \to [0, 1]$ be a smooth bump function supported on $[-\frac{8}{5}, \frac{8}{5}]$ and $\phi \equiv 1$ on $[-\frac{5}{4}, \frac{5}{4}]$. For $\xi \in \mathbb{R}^3$, we set $\phi_0(\xi) = \phi(|\xi|)$ and

$$\phi_j(\xi) = \phi\left(\frac{|\xi|}{2^j}\right) - \phi\left(\frac{|\xi|}{2^{j-1}}\right)$$

for $j \in \mathbb{N}$. Then, for $j \in \mathbb{N}_0 := \mathbb{N} \cup \{0\}$, we define the Littlewood-Paley projector $P_j$ as the Fourier multiplier operator with a symbol $\varphi_j$ given by

$$\varphi_j(\xi) = \frac{\phi_j(\xi)}{\sum_{k \in \mathbb{N}_0} \phi_k(\xi)}.$$  \hfill (2.1)

Note that, for each $\xi \in \mathbb{R}^3$, the sum in the denominator is over finitely many $k$’s. Thanks to the normalization $\|\varphi_j\|_{L^\infty} = 1$, we have

$$f = \sum_{j=0}^{\infty} P_j f,$$

which is used in (1.22).

We briefly recall the basic properties of the Besov spaces $B^{s}_{p,q}(\mathbb{T}^3)$ defined by the norm:

$$\|u\|_{B^{s}_{p,q}} = \left\|2^{sj}\|P_j u\|_{L^p}\right\|_{\ell^q(\mathbb{N}_0)}.$$

Note that $H^s(\mathbb{T}^3) = B^{s}_{2,2}(\mathbb{T}^3)$.

**Lemma 2.1.** (i) (paraproduct and resonant product estimates) Let $s_1, s_2 \in \mathbb{R}$ and $1 \leq p, p_1, p_2, q \leq \infty$ such that $\frac{1}{p} = \frac{1}{p_1} + \frac{1}{p_2}$. Then, we have

$$\|f \otimes g\|_{B^{s_1}_{p_1,q}} \lesssim \|f\|_{L^{p_1}} \|g\|_{B^{s_2}_{p_2,q}}.$$ \hfill (2.2)

When $s_1 < 0$, we have

$$\|f \otimes g\|_{B^{s_1+s_2}_{p_1+1,q}} \lesssim \|f\|_{B^{s_1}_{p_1,q}} \|g\|_{B^{s_2}_{p_2,q}}.$$ \hfill (2.3)

When $s_1 + s_2 > 0$, we have

$$\|f \otimes g\|_{B^{s_1+s_2}_{p_1,q}} \lesssim \|f\|_{B^{s_1}_{p_1,q}} \|g\|_{B^{s_2}_{p_2,q}}.$$ \hfill (2.4)

(ii) Let $s_1 < s_2$ and $1 \leq p, q \leq \infty$. Then, we have

$$\|u\|_{B^{s_1}_{p,q}} \lesssim \|u\|_{W^{s_2,p}}.$$ \hfill (2.5)
The product estimates (2.2), (2.3), and (2.4) follow easily from the definition (1.22) of the paraproduct and the resonant product. See [3] [64] for details of the proofs in the non-periodic case (which can be easily extended to the current periodic setting). The embedding (2.5) follows from the $\ell^q$-summability of $\{2^{(s_1-s_2)j}\}_{j\in\mathbb{N}_0}$ for $s_1 < s_2$ and the uniform boundedness of the Littlewood-Paley projector $P_j$.

We also recall the following fractional Leibniz rule.

**Lemma 2.2.** Let $0 \leq s \leq 1$. Suppose that $1 < p_j, q_j, r < \infty$, $\frac{1}{p_j} + \frac{1}{q_j} = \frac{1}{s_j}$, $j = 1, 2$. Then, we have

$$\|\langle \nabla \rangle^s (fg)\|_{L^r(T^d)} \lesssim \|f\|_{L^{p_1}(T^d)} \|\langle \nabla \rangle^s g\|_{L^{q_1}(T^d)} + \|\langle \nabla \rangle^s f\|_{L^{p_2}(T^d)} \|g\|_{L^{q_2}(T^d)}.$$  

This lemma follows from the Coifman–Meyer theorem on $\mathbb{R}^d$ (see [21] and the inequality (1.1) in [67]) and the transference principle [26, Theorem 3].

**2.2. On discrete convolutions.** Next, we recall the following basic lemma on a discrete convolution.

**Lemma 2.3.** (i) Let $d \geq 1$ and $\alpha, \beta \in \mathbb{R}$ satisfy

$$\alpha + \beta > d \quad \text{and} \quad \alpha, \beta < d.$$  

Then, we have

$$\sum_{n=n_1+n_2} \frac{1}{\langle n_1 \rangle^\alpha \langle n_2 \rangle^\beta} \lesssim \langle n \rangle^{d-\alpha-\beta}$$

for any $n \in \mathbb{Z}^d$.

(ii) Let $d \geq 1$ and $\alpha, \beta \in \mathbb{R}$ satisfy $\alpha + \beta > d$. Then, we have

$$\sum_{n=n_1+n_2} \frac{1}{\langle n_1 \rangle^\alpha \langle n_2 \rangle^\beta} \lesssim \langle n \rangle^{d-\alpha-\beta}$$

for any $n \in \mathbb{Z}^d$.

Namely, in the resonant case (ii), we do not have the restriction $\alpha, \beta < d$. Lemma 2.3 follows from elementary computations. See, for example, Lemmas 4.1 and 4.2 in [66] for the proof.

**2.3. Strichartz estimates.** Given $0 \leq s \leq 1$, we say that a pair $(q, r)$ is $s$-admissible (a pair $(\bar{q}, \bar{r})$ is dual $s$-admissible) respectively if $1 \leq \bar{q} < 2 < q \leq \infty$, $1 < \bar{r} \leq 2 \leq r \leq \infty$,

$$\frac{1}{q} + \frac{3}{r} = \frac{3}{2} - s = \frac{1}{\bar{q}} + \frac{3}{\bar{r}} - 2, \quad \frac{1}{q} + \frac{1}{r} = \frac{1}{2}, \quad \text{and} \quad \frac{1}{\bar{q}} + \frac{1}{\bar{r}} \geq \frac{3}{2}.$$  

We refer to the first two equalities as the scaling conditions and the last two inequalities as the admissibility conditions.

We say that $u$ is a solution to the following nonhomogeneous linear wave equation:

$$\begin{cases} 
(\partial_t^2 + 1 - \Delta)u = f \\
(u, \partial_t u)|_{t=0} = (u_0, u_1)
\end{cases} \tag{2.6}$$

on a time interval containing $t = 0$, if $u$ satisfies the following Duhamel formulation:

$$u = \cos(t \langle \nabla \rangle)u_0 + \sin(t \langle \nabla \rangle)u_1 + \int_0^t \sin((t-t') \langle \nabla \rangle) \frac{f(t')}{\langle \nabla \rangle} dt'.$$

\footnote{Here, we define the notion of dual $s$-admissibility for the convenience of the presentation. Note that $(\bar{q}, \bar{r})$ is dual $s$-admissible if and only if $(\bar{q}', \bar{r}')$ is $(1-s)$-admissible.}
In the following, we often use the following short-hand notation:
\[ I(f)(t) = \int_0^t \frac{\sin((t-t')(\nabla))}{\langle \nabla \rangle} f(t') dt'. \]

We now recall the Strichartz estimates for solutions to the nonhomogeneous linear wave equation (2.6).

**Lemma 2.4.** Given \( 0 \leq s \leq 1 \), let \((q,r)\) and \((\tilde{q},\tilde{r})\) be \(s\)-admissible and dual \(s\)-admissible pairs, respectively. Then, a solution \( u \) to the nonhomogeneous linear wave equation (2.6) satisfies
\[ \|(u, \partial_t u)\|_{L^\infty_t H^s} + \|u\|_{L^q_t L^r_x} \lesssim \|(u_0, u_1)\|_{H^s} + \|f\|_{L^q_t L^{r'}_x} \]
for all \( 0 < T \leq 1 \). The following estimate also holds:
\[ \|(u, \partial_t u)\|_{L^\infty_t H^s} + \|u\|_{L^q_t L^r_x} \lesssim \|(u_0, u_1)\|_{H^s} + \|f\|_{L^q_t H^{s-1}_x} \]
for all \( 0 < T \leq 1 \). Here, we used a shorthand notation \( L^q_t L^r_x = L^q([0,T]; L^r(T^3)) \), etc.

The Strichartz estimates on \( \mathbb{R}^d \) have been studied extensively by many mathematicians. See [31, 59, 55] in the context of the wave equation. For the Klein-Gordon equation under consideration, see [56]. Thanks to the finite speed of propagation, these estimates on \( \mathbb{T}^3 \) follow from the corresponding estimates on \( \mathbb{R}^3 \).

In proving Theorem 1.12, we use the fact that \( (8, \frac{8}{3}) \) and \( (4, 4) \) are \( \frac{1}{4} \)-admissible and \( \frac{3}{2} \)-admissible, respectively. We also use a dual \( \frac{3}{4} \)-admissible pair \((\frac{4}{3}, \frac{3}{4})\). In proving Theorem 1.2 we use \( (\frac{4}{3-2\sigma}, \frac{4}{3+2\sigma}) \) and \( (\frac{4}{3+8\sigma}, \frac{4}{3-4\sigma}) \) which are \( \frac{1}{2} + \sigma \)-admissible and dual \( \frac{1}{2} + \sigma \)-admissible, respectively, for small \( \sigma > 0 \).

### 2.4. Tools from stochastic analysis

We conclude this section by recalling useful lemmas from stochastic analysis. See [9, 85] for basic definitions. Let \((H, B, \mu)\) be an abstract Wiener space. Namely, \( \mu \) is a Gaussian measure on a separable Banach space \( B \) with \( H \subset B \) as its Cameron-Martin space. Given a complete orthonormal system \( \{e_j\}_{j \in \mathbb{N}} \subset B^* \) of \( H^* = H \), we define a polynomial chaos of order \( k \) to be an element of the form \( \prod_{j=1}^\infty H_{k_j}((x, e_j)) \), where \( x \in B \), \( k_j \neq 0 \) for only finitely many \( j \)'s, \( k = \sum_{j=1}^{\infty} k_j \), \( H_{k_j} \) is the Hermite polynomial of degree \( k_j \), and \( \langle \cdot, \cdot \rangle = B(\cdot, \cdot)^* \) denotes the \( B-B^* \) duality pairing. We then denote the closure of polynomial chaoses of order \( k \) under \( L^2(B, \mu) \) by \( H_k \). The elements in \( H_k \) are called homogeneous Wiener chaoses of order \( k \). We also set
\[ H_{\leq k} = \bigoplus_{j=0}^k H_j \]
for \( k \in \mathbb{N} \).

Let \( L = \Delta - x \cdot \nabla \) be the Ornstein-Uhlenbeck operator\(^{18}\). Then, it is known that any element in \( H_k \) is an eigenfunction of \( L \) with eigenvalue \(-k\). Then, as a consequence of the hypercontractivity of the Ornstein-Uhlenbeck semigroup \( U(t) = e^{tL} \) due to Nelson [68], we have the following Wiener chaos estimate [88, Theorem I.22]. See also [88 Proposition 2.4].

**Lemma 2.5.** Let \( k \in \mathbb{N} \). Then, we have
\[ \|X\|_{L^p(\Omega)} \leq (p-1)^{1/2} \|X\|_{L^2(\Omega)} \]
for any \( p \geq 2 \) and any \( X \in H_{\leq k} \).

\(^{18}\)For simplicity, we write the definition of the Ornstein-Uhlenbeck operator \( L \) when \( B = \mathbb{R}^d \).
The following lemma will be used in studying regularities of stochastic objects. We say that a stochastic process $X : \mathbb{R}_+ \to \mathcal{D}'(\mathbb{T}^d)$ is spatially homogeneous if $\{X(\cdot, t)\}_{t \in \mathbb{R}_+}$ and $\{X(x_0 + \cdot, t)\}_{t \in \mathbb{R}_+}$ have the same law for any $x_0 \in \mathbb{T}^d$. Given $h \in \mathbb{R}$, we define the difference operator $\delta_h$ by setting
\[ \delta_h X(t) = X(t + h) - X(t). \]  

**Lemma 2.6.** Let $\{X_N\}_{N \in \mathbb{N}}$ and $X$ be spatially homogeneous stochastic processes : $\mathbb{R}_+ \to \mathcal{D}'(\mathbb{T}^d)$. Suppose that there exists $k \in \mathbb{N}$ such that $X_N(t)$ and $X(t)$ belong to $\mathcal{H}_{\leq k}$ for each $t \in \mathbb{R}_+$.

(i) Let $t \in \mathbb{R}_+$. If there exists $s_0 \in \mathbb{R}$ such that
\[ \mathbb{E}[|\tilde{X}(n, t)|^2] \lesssim \langle n \rangle^{-d-2s_0} \]
for any $n \in \mathbb{Z}^d$, then we have $X(t) \in W^{s, \infty}(\mathbb{T}^d)$, $s < s_0$, almost surely. Furthermore, if there exists $\gamma > 0$ such that
\[ \mathbb{E}[|\tilde{X}_N(n, t) - \tilde{X}(n, t)|^2] \lesssim N^{-\gamma} \langle n \rangle^{-d-2s_0} \]
for any $n \in \mathbb{Z}^d$ and $N \geq 1$, then $X_N(t)$ converges to $X(t)$ in $W^{s, \infty}(\mathbb{T}^d)$, $s < s_0$, almost surely.

(ii) Let $T > 0$ and suppose that (i) holds on $[0, T]$. If there exists $\sigma \in (0, 1)$ such that
\[ \mathbb{E}[|\delta_h \tilde{X}(n, t)|^2] \lesssim \langle n \rangle^{-d-2s_0 + \sigma} |h|^\sigma, \]
for any $n \in \mathbb{Z}^d$, $t \in [0, T]$, and $h \in [-1, 1]^d$, then we have $X \in C([0, T]; W^{s, \infty}(\mathbb{T}^d))$, $s < s_0 - \frac{\sigma}{2}$, almost surely. Furthermore, if there exists $\gamma > 0$ such that
\[ \mathbb{E}[|\delta_h \tilde{X}_N(n, t) - \delta_h \tilde{X}(n, t)|^2] \lesssim N^{-\gamma} \langle n \rangle^{-d-2s_0 + \sigma} |h|^\sigma, \]
for any $n \in \mathbb{Z}^d$, $t \in [0, T]$, $h \in [-1, 1]$, and $N \geq 1$, then $X_N$ converges to $X$ in $C([0, T]; W^{s, \infty}(\mathbb{T}^d))$, $s < s_0 - \frac{\sigma}{2}$, almost surely.

Lemma 2.6 follows from a straightforward application of the Wiener chaos estimate (Lemma 2.5). For the proof, see Proposition 3.6 in [66] and Appendix in [76]. As compared to Proposition 3.6 in [66], we made small adjustments. In studying the time regularity, we made the following modifications: $\langle n \rangle^{-d-2s_0 + 2\sigma} \rightarrow \langle n \rangle^{-d-2s_0 + \sigma}$ and $s < s_0 - \sigma \rightarrow s < s_0 - \frac{\sigma}{2}$ so that it is suitable for studying the wave equation. Moreover, while the result in [66] is stated in terms of the Besov-Hölder space $C^\alpha(\mathbb{T}^d) = B^{s, \infty}(\mathbb{T}^d)$, Lemma 2.6 handles the $L^\infty$-based Sobolev space $W^{s, \infty}(\mathbb{T}^d)$. Note that the required modification of the proof is straightforward since $W^{s, \infty}(\mathbb{T}^d)$ and $B^{s, \infty}(\mathbb{T}^d)$ differ only logarithmically:
\[ \|f\|_{W^{s, \infty}} \leq \sum_{j=0}^{\infty} \|P_j f\|_{W^{s, \infty}} \lesssim \|f\|_{B^{s, \infty}}, \]
for any $\varepsilon > 0$. For the proof of the almost sure convergence claims, see [76].

Lastly, we recall the following Wick’s theorem. See Proposition I.2 in [86].

**Lemma 2.7.** Let $g_1, \ldots, g_{2n}$ be (not necessarily distinct) real-valued jointly Gaussian random variables. Then, we have
\[ \mathbb{E}[g_1 \cdots g_{2n}] = \sum_{k=1}^{n} \prod_{j=1}^{n} \mathbb{E}[g_{i_k} g_{j_k}], \]
where the sum is over all partitions of $\{1, \ldots, 2n\}$ into disjoint pairs $(i_k, j_k)$.

\[\text{We impose } h \geq -t \text{ such that } t + h \geq 0.\]
3. On the stochastic terms, Part I

In this and the next sections, we establish the regularity properties of the stochastic objects \( \mathfrak{t} \), \( \mathcal{Y} \), and \( \mathcal{H} \) defined in (1.14), (1.15), and (1.26), respectively. The following lemma establishes the regularity properties of the stochastic convolution \( \mathfrak{t} \) and the Wick power \( \nu \). See also the proof of Proposition 2.1 in [36].

**Lemma 3.1.** Let \( T > 0 \).

(i) For any \( \varepsilon > 0 \), \( 1_N \) in (1.18) converges to \( \mathfrak{t} \) in \( C([0, T]; W^{-\frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3)) \) almost surely. In particular, we have

\[
\mathfrak{t} \in C([0, T]; W^{-\frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3))
\]

almost surely.

(ii) For any \( \varepsilon > 0 \), \( \nu_N \) in (1.19) converges to \( \nu \) in \( C([0, T]; W^{-1 - \varepsilon, \infty}(\mathbb{T}^3)) \) almost surely. In particular, we have

\[
\nu \in C([0, T]; W^{-1 - \varepsilon, \infty}(\mathbb{T}^3))
\]

almost surely.

**Proof.** (i) Let \( t \geq 0 \). From (1.9), we have

\[
\hat{\mathfrak{t}}(n, t) = \int_0^t \frac{\sin((t - t')(n))}{\langle n \rangle} d\beta_n(t')
\]

and thus

\[
\mathbb{E}[|\hat{\mathfrak{t}}(n, t)|^2] = \int_0^t \left| \frac{\sin((t - t')(n))}{\langle n \rangle} \right|^2 dt' = \frac{t}{2\langle n \rangle^2} - \frac{\sin(2t\langle n \rangle)}{4\langle n \rangle^3}
\]

\[
\leq C(t)\langle n \rangle^{-2}
\]

for any \( n \in \mathbb{Z}^3 \). Hence from Lemma 2.6, we conclude that \( \mathfrak{t}(t) \in W^{-\frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3) \) almost surely for any \( \varepsilon > 0 \).

Let \( 0 \leq t_2 \leq t_1 \). From (1.9), we have

\[
\hat{\mathfrak{t}}(n, t_1) - \hat{\mathfrak{t}}(n, t_2) = \int_{t_2}^{t_1} \frac{\sin((t_1 - t')(n))}{\langle n \rangle} d\beta_n(t')
\]

\[
+ \int_0^{t_2} \frac{\sin((t_1 - t')(n)) - \sin((t_2 - t')(n))}{\langle n \rangle} d\beta_n(t').
\]

Then, from the mean value theorem, we have

\[
\mathbb{E}[|\hat{\mathfrak{t}}(n, t_1) - \hat{\mathfrak{t}}(n, t_2)|^2] \leq \langle n \rangle^{-2}|t_1 - t_2| + t_2\langle n \rangle^{-2+\sigma}|t_1 - t_2|^\sigma
\]

\[
\leq C(t_2)\langle n \rangle^{-2+\sigma}|t_1 - t_2|^\sigma
\]

for any \( n \in \mathbb{Z}^3 \), \( 0 \leq t_2 \leq t_1 \) with \( t_1 - t_2 \leq 1 \), and \( \sigma \in [0, 1] \). Hence, from Lemma 2.6 we conclude that \( \mathfrak{t}(t) \in C(\mathbb{R}_+; W^{-\frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3)) \) almost surely for any \( \varepsilon > 0 \).

Proceeding as above, we have

\[
\mathbb{E}[|\hat{\mathfrak{t}}_M(n, t) - \hat{\mathfrak{t}}_N(n, t)|^2] \leq C(t)1_{|n| > N} \cdot \langle n \rangle^{-2} \leq C(t)N^{-\gamma}\langle n \rangle^{-2+\gamma}
\]

for any \( n \in \mathbb{Z}^3 \), \( M \geq N \geq 1 \), and \( \gamma \geq 0 \). Similarly, with \( \delta_h \) as in (2.7), we have

\[
\mathbb{E}[|\delta_h \hat{\mathfrak{t}}_M(n, t) - \delta_h \hat{\mathfrak{t}}_N(n, t)|^2] \lesssim C(t)1_{|n| > N} \cdot \langle n \rangle^{-2+\sigma}|h|^\sigma
\]

\[
\lesssim C(t)N^{-\gamma}\langle n \rangle^{-2+\sigma+\gamma}|h|^\sigma
\]
for any \( n \in \mathbb{Z}^3, M \geq N \geq 1, h \in [-1,1], \gamma \geq 0, \) and \( \sigma \in [0,1]. \) Therefore, it follows from Lemma 2.6 that given \( T > 0 \) and \( \varepsilon > 0, \) the truncated stochastic convolution \( \tau_N \) converges to \( \tau \) in \( C([0,T]; W^{-\frac{1}{2}-\varepsilon,\infty}(\mathbb{T}^3)) \) almost surely.

(ii) Proceeding as in Part (i), the main task is to estimate \( \mathbb{E}[\hat{\nabla}(n,t)^2]. \) The following discussion holds for \( \nabla_N \) with constants independent of \( N \in \mathbb{N} \cup \{\infty\}. \) From (1.19) and (1.20), we have

\[
\mathbb{E}[\hat{\nabla}(n,t)^2] = \sum_{n=n_1+n_2}^{n=n_1'+n_2'} \mathbb{E}\left[\left(\hat{\nabla}(n_1,t)\hat{\nabla}(n_2,t) - 1_n \cdot \mathbb{E}[\hat{\nabla}(n_1,t)^2]\right)\right. \\
\times \left.\left(\hat{\nabla}(n_1',t)\hat{\nabla}(n_2',t) - 1_{n_1} \cdot \mathbb{E}[\hat{\nabla}(n_1',t)^2]\right)\right].
\]

In order to have non-zero contribution in (3.5), we must have \( n_1 = n_1' \) and \( n_2 = n_2' \) up to permutation. Thus, with (1.9) and Lemma 2.3, we have

\[
\mathbb{E}[\hat{\nabla}(n,t)^2] \lesssim t^2 \sum_{n=n_1+n_2}^{n=n_1'+n_2'} \frac{1}{(n_1)^2(n_2)} \lesssim t^2 \langle n \rangle^{-1}. \tag{3.6}
\]

Hence from Lemma 2.6, we conclude that \( \nabla(t) \in W^{-1-\varepsilon,\infty}(\mathbb{T}^3) \) almost surely for any \( \varepsilon > 0. \) A similar argument shows that \( \nabla \in C([0,T]; W^{-1-\varepsilon,\infty}(\mathbb{T}^3)) \) almost surely and that \( \nabla_N \) converges to \( \nabla \) in \( C([0,T]; W^{-1-\varepsilon,\infty}(\mathbb{T}^3)) \) almost surely. \( \square \)

**Remark 3.2.** As we saw in the proof of Lemma 3.1 (i), once we establish regularity properties of a given stochastic object \( \tau \), then a slight modification of the argument shows convergence of the truncated stochastic objects \( \tau_N \) to \( \tau \). Hence, in the following, we only establish claimed regularity properties of given stochastic terms.

Next, we study the regularity of \( \nabla. \) As pointed in the introduction, a naive parabolic thinking would give a regularity of \( 0 - (-\frac{1}{2}) = -\frac{1}{2} + 1, \) where one degree of smoothing comes from the Duhamel integral operator \( \mathcal{I}. \) By exploiting multilinear dispersive effect, we show that there is in fact an extra \( \frac{1}{2} \)-smoothing.

**Proof of Proposition 1.6** By definition \( \nabla = \mathcal{I}(\nabla), \) we have

\[
\hat{\nabla}(n,t) = \int_0^t \frac{\sin((t-t')\langle n \rangle)}{\langle n \rangle} \hat{\nabla}(n,t') dt'.
\]

and thus we have

\[
\partial_t \hat{\nabla}(n,t) = \int_0^t \cos((t-t')\langle n \rangle) \hat{\nabla}(n,t') dt'.
\]

Then, from (the proof of) Lemma 3.1 (ii), we conclude that

\[
\partial_t \nabla \in C([0,T]; W^{-1-\varepsilon,\infty}(\mathbb{T}^3))
\]

almost surely for any \( \varepsilon > 0. \)

In the following, we focus on proving that \( \nabla \in C([0,T]; W^{\frac{1}{2}-\varepsilon,\infty}(\mathbb{T}^3)) \) almost surely. In view of Lemma 2.6, it suffices to show that there exists small \( \sigma \in (0,1) \) such that

\[
\mathbb{E}[\hat{\nabla}(n,t)^2] \leq C(T)\langle n \rangle^{-4+}, \tag{3.8}
\]

\[
\mathbb{E}[|\hat{\nabla}(n,t_1) - \hat{\nabla}(n,t_2)|^2] \leq C(T)\langle n \rangle^{-4+}\sigma^{|t_1 - t_2|} \tag{3.9}
\]

for any \( n \in \mathbb{Z}^3 \) and \( 0 \leq t, t_1, t_2 \leq T \) with \( 0 < |t_1 - t_2| < 1. \)
We first prove \( (3.8) \) in the following. From \( (3.7) \), we have
\[
E[|\hat{\mathcal{Y}}(n, t)|^2] = \int_0^t \int_0^t \frac{\sin((t - t_1)(n))}{n} \frac{\sin((t - t_2)(n))}{n} E[\hat{\mathcal{Y}}(n, t_1)\hat{\mathcal{Y}}(n, t_2)] dt_1 dt_2.
\]
(3.10)

When \( n = 0 \), it follows from \( (1.19) \) with \( (1.20) \) and \( (1.32) \) that, we have
\[
E[|\hat{\mathcal{Y}}(0, t)|^2] = \int_0^t \int_0^t \sin(t - t_1) \sin(t - t_2) E[\hat{\mathcal{Y}}(0, t_1)\hat{\mathcal{Y}}(0, t_2)] dt_1 dt_2
\]
\[
= \int_0^t \sin(t - t_1) \int_0^t \sin(t - t_2) \times \sum_{k_1, k_2 \in \mathbb{Z}^3} E[|\hat{n}(k_1, t_1)|^2 - \sigma_{k_1}(t_1, t_1) (|\hat{n}(k_2, t_2)|^2 - \sigma_{k_2}(t_2, t_2))] dt_1 dt_2
\]
\[
\leq C(T) \sum_{k \in \mathbb{Z}^3} \frac{1}{|k|^4} \leq C(T),
\]
where \( \sigma_{k_j}(t_j, t_j) \) is as in \( (1.32) \). In the last step, we used
\[
E[|\hat{n}(k_1, t_1)|^2 - \sigma_{k_1}(t_1, t_1) (|\hat{n}(k_2, t_2)|^2 - \sigma_{k_2}(t_2, t_2)))] = 1_{k_1 = \pm k_2} \cdot \sigma_{k_1}(t_1, t_2)^2.
\]
(3.11)
The identity \( (3.11) \) follows from Wick’s theorem (Lemma 2.7). This proves \( (3.8) \) when \( n = 0 \). In the following, we assume \( n \neq 0 \). By expanding \( \hat{\mathcal{Y}}(n, t_1) \) and \( \hat{\mathcal{Y}}(n, t_2) \) as in \( (3.5) \) with \( n = n_1 + n_2 \) for \( \hat{\mathcal{Y}}(n, t_1) \) and \( n = n'_1 + n'_2 \) for \( \hat{\mathcal{Y}}(n, t_2) \), we see that we must have \( n_1 = n'_1 \) and \( n_2 = n'_2 \) up to permutation in order to have non-zero contribution in \( (3.10) \). Without loss of generality, assume that \( 0 \leq t_2 \leq t_1 \leq t \). Then, we have
\[
E[|\hat{\mathcal{Y}}(n, t)|^2] = 4 \sum_{n=n_1+n_2, n_1 \neq \pm n_2} \int_0^t \int_0^t \frac{\sin((t - t_1)(n))}{n} \frac{\sin((t - t_2)(n))}{n} \sigma_{n_1}(t_1, t_2) \sigma_{n_2}(t_1, t_2) dt_1 dt_2
\]
\[
+ 2 \cdot 1_{n \in \mathbb{Z}^3 \setminus \{0\} } \int_0^t \int_0^t \frac{\sin((t - t_1)(n))}{n} \frac{\sin((t - t_2)(n))}{n} \times E[\hat{\mathcal{Y}}(\frac{n}{2}, t_1)^2 \hat{\mathcal{Y}}(\frac{n}{2}, t_2)^2] dt_1 dt_2
\]
\[
=: I(n, t) + \Pi(n, t),
\]
(3.12)
where \( \sigma_{n_j}(t_1, t_2) \) is as in \( (1.32) \) and \( \Pi(n, t) \) denotes the contribution from \( n_1 = n_2 = n'_1 = n'_2 = \frac{n}{2} \).

We first estimate the second term \( \Pi(n, t) \) in \( (3.12) \). By Wick’s theorem (Lemma 2.7) with \( (1.32) \), we have
\[
E[\hat{\mathcal{Y}}(\frac{n}{2}, t_1)^2 \hat{\mathcal{Y}}(\frac{n}{2}, t_2)^2] \leq C(T) \langle n \rangle^{-4}
\]
under \( 0 \leq t_2 \leq t_1 \leq t \leq T \). Hence, from \( (3.12) \), we conclude that
\[
|\Pi(n, t)| \leq C(T) \langle n \rangle^{-6},
\]
verifying \( (3.8) \).
In the following, we estimate $I(n,t)$ in (3.12):

$$I(n,t) = -\sum_{k_1,k_2 \in \{1,2\}} \sum_{\varepsilon_1,\varepsilon_2 \in \{-1,1\}} \frac{\varepsilon_1 \varepsilon_2 e^{i(\varepsilon_1 + \varepsilon_2)\tau(n)}}{(\tau(n))^2} \sum_{n=1 + n_2 \neq n_1} \int_0^t e^{-i\varepsilon_1 \tau(n)} \times \int_0^{t_1} e^{-i\varepsilon_2 \tau(n)} \frac{2}{\sigma^{(k_1)}_{n_1}(t_1,t_2)} dt_2 dt_1 =: \sum_{k_1,k_2 \in \{1,2\}} I^{(k_1,k_2)}(n,t),$$

(3.13)

where $\sigma^{(1)}_n(t_1,t_2)$ and $\sigma^{(2)}_n(t_1,t_2)$ are defined by

$$\sigma^{(1)}_n(t_1,t_2) := \frac{\cos((t_1 - t_2)\langle n \rangle)}{2\langle n \rangle^2}$$

$$\sigma^{(2)}_n(t_1,t_2) := \frac{\sin((t_1 - t_2)\langle n \rangle)}{4\langle n \rangle^3} - \frac{\sin((t_1 + t_2)\langle n \rangle)}{4\langle n \rangle^3}$$

(3.14)

such that $\sigma_n(t_1,t_2) = \sigma^{(1)}_n(t_1,t_2) + \sigma^{(2)}_n(t_1,t_2)$. If $|n_1| \sim 1$ or $|n_2| \sim 1$, then from (3.14) with $\langle n_1 \rangle \langle n_2 \rangle \gtrsim \langle n \rangle$, we easily obtain

$$|I(n,t)| \leq C(T)\langle n \rangle^{-4+},$$

(3.15)

satisfying (3.8). Hence, we assume $|n_1|, |n_2| \gg 1$ in the following. By Lemma 2.3 with (3.14), we can easily bound the contribution to $I(n,t)$ in (3.13) from $(k_1,k_2) \neq (1,1)$ and obtain for them the decay required in (3.15). In the following, we estimate the worst contribution to $I(n,t)$ coming from $(k_1,k_2) = (1,1)$:

$$I^{(1,1)}(n,t) := -\frac{1}{16} \sum_{\varepsilon_1,\varepsilon_2,\varepsilon_3,\varepsilon_4 \in \{-1,1\}} \sum_{n=1 + n_2 \neq n_1} \frac{\varepsilon_1 \varepsilon_2 e^{i(\varepsilon_1 + \varepsilon_2)\tau(n)}}{(\tau(n))^2(\tau(n_1))^2(\tau(n_2))^2} \times \int_0^t \int_0^{t_1} e^{-i\varepsilon_1 \kappa_1(\bar{n})} \int_0^{t_1} t_2 e^{-i\varepsilon_2 \kappa_2(\bar{n})} dt_2 dt_1,$$

where $\kappa_1(\bar{n})$ and $\kappa_2(\bar{n})$ are defined by

$$\kappa_1(\bar{n}) = \varepsilon_1 \langle n \rangle - \varepsilon_3 \langle n_1 \rangle - \varepsilon_4 \langle n_2 \rangle,$$

$$\kappa_2(\bar{n}) = \varepsilon_2 \langle n \rangle + \varepsilon_3 \langle n_1 \rangle + \varepsilon_4 \langle n_2 \rangle.$$

When $|n| \lesssim 1$, (3.15) trivially holds. Hence, we assume $|n| \gg 1$. We have to carefully estimate the different contributions coming from the various combinations of $\bar{\varepsilon} = (\varepsilon_1,\varepsilon_2,\varepsilon_3,\varepsilon_4)$ by exploiting either (i) the dispersion (= oscillation) or (ii) smallness of the measure of the relevant frequency set.

Fix our choice of $\bar{\varepsilon} = (\varepsilon_1,\varepsilon_2,\varepsilon_3,\varepsilon_4)$ and denote by $I^{(1,1)}_\varepsilon(n,t)$ the associated contribution to $I^{(1,1)}(n,t)$. By switching the order of integration and first integrating in $t_1$, we have

$$\left| \int_0^t e^{-i\varepsilon_1 \kappa_1(\bar{n})} \int_0^{t_1} t_2 e^{-i\varepsilon_2 \kappa_2(\bar{n})} dt_2 dt_1 \right| = \left| \int_0^t t_2 e^{-i\varepsilon_2 \kappa_2(\bar{n})} \frac{e^{-i\varepsilon_1 \kappa_1(\bar{n})} - e^{-i\varepsilon_2 \kappa_1(\bar{n})}}{-i\kappa_1(\bar{n})} dt_2 \right| \leq C(T)(1 + |\kappa_1(\bar{n})|)^{-1}.$$

Thus, we have

$$|I^{(1,1)}_\varepsilon(n,t)| \leq C(T) \sum_{n=1 + n_2} \frac{1}{(\tau(n))^2(\tau(n_1))^2(\tau(n_2))^2(1 + |\kappa_1(\bar{n})|)}.$$

(3.16)
Without loss of generality, by symmetry we can assume $|n_1| \geq |n_2|$ in the following when estimating the sum on the right hand side.

- **Case 1:** $(\varepsilon_1, \varepsilon_3, \varepsilon_4) = (\pm 1, \mp 1, 1)$ or $(\pm 1, 1, \pm 1)$.
  
  In this case, we have $|\kappa_1(n)| \geq \langle n \rangle$. Then, from Lemma 2.3, we obtain
  \[ |I_{\varepsilon_1}^{(1,1)}(n, t)| \leq C(T)\langle n \rangle^{-4}. \]
  This proves (3.8).

- **Case 2:** $(\varepsilon_1, \varepsilon_3, \varepsilon_4) = (\pm 1, 1, \pm 1)$.

  In this case, we have $|\kappa_1(n)\rangle = \langle n \rangle + \langle n_2 \rangle - \langle n_1 \rangle$. Under $n = n_1 + n_2$ and $|n_1| \geq |n_2|$, we have
  \[ \langle n_1 \rangle \sim \langle n \rangle + \langle n_2 \rangle. \] (3.17)

  Under $n = n_1 + n_2$, three vectors $n, n_1, \text{ and } n_2$ form a triangle, where we view $n_1$ with a vector based at $n_2$. Then, by the law of cosines, we have
  \[ |n|^2 + |n_2|^2 - |n_1|^2 = 2|n||n_2| \cos (\angle(n, n_2)), \] (3.18)
  where $\angle(n, n_2)$ denotes the angle between $n$ and $n_2$. Then, from (3.17) and (3.18), we have
  \[ |\kappa_1(n)| = \frac{(|\langle n \rangle + |n_2\rangle|^2 - |n_1|^2)}{|\langle n \rangle + |n_2\rangle + |n_1\rangle|} = \frac{2\langle n \rangle \langle n_2 \rangle + |n|^2 + |n_2|^2 - |n_1|^2 + 1}{\langle n \rangle + \langle n_2 \rangle + \langle n_1 \rangle} \] (3.19)

  where $\theta = \angle(n_2, -n) \in [0, \pi]$ is the angle between $n_2$ and $-n$.

  **Subcase 2.i:** We first consider the case $1 - \cos \theta \gtrsim 1$. See Figure 2. In this case, from (3.16) and (3.19) with Lemma 2.3, we have
  \[ |I_{\varepsilon_1}^{(1,1)}(n, t)| \leq C(T) \sum_{n=n_1+n_2} \frac{1}{(n)^3(n_1)^3(n_2)^3} \] (3.20)

  yielding (3.8).

  ![Figure 2. A typical configuration in Subcase 2.i](image)

  **Subcase 2.ii:** Next, we consider the case $1 - \cos \theta \ll 1$. In this case, we have $0 \leq \theta \ll 1$, namely, $n$ and $n_2$ point in almost opposite directions. In particular, we have $1 - \cos \theta \sim \theta^2 \ll 1$. By dyadically decomposing $n_2$ into $|n_2| \sim N_2$ for dyadic $N_2 \geq 1$, we see that for fixed $n \in \mathbb{Z}^3$, the range of possible $n_2$ with $|n_2| \sim N_2$ is constrained to a cone $C$ whose height is $\sim N_2 \cos \theta \sim N_2$ and the base disc of radius $\sim N_2 \sin \theta \sim N_2 \theta$ with the direction of the central axis of the cone...
given by \(-n\). Hence, we have \(\text{vol}(C) \sim N_2^3 \theta^2\). See Figure 3. Then, from (3.16) and (3.19) with \(|n_1| \gtrsim \max(|n|,|n_2|)\), we have

\[
|\varphi_{1,1}(\xi,n) - \varphi_{2,1}(\xi,n)| \leq C(T) \sum_{\text{dyadic } N_2 \geq 1} \frac{1}{\langle n \rangle^2 \max(\langle n \rangle, N_2) N_2^2 \theta^2} N_2^3 \theta^2
\]

\[
\leq C(T) \langle n \rangle^{-4+},
\]

yielding (3.8).

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{example_diagram.png}
\caption{A typical configuration in Subcase 2.ii. Here, we omit the vector \(n_1\).
\bullet Case 3: \((\varepsilon_1, \varepsilon_3, \varepsilon_4) = (\pm 1, \pm 1, \pm 1)\).

In this case, we have \(|\kappa_1(n) = \langle n_1 \rangle + \langle n_2 \rangle - \langle n \rangle\). By the law of cosines, we have

\[
|n_1|^2 + |n_2|^2 - |n|^2 = 2|n_1||n_2| \cos(\angle(n_1, n_2)).
\]

Then, by proceeding as in Case 2 with (3.17) and (3.22), we have

\[
|\kappa_1(n)| = \frac{(\langle n_1 \rangle + \langle n_2 \rangle)^2 - \langle n \rangle^2}{\langle n_1 \rangle + \langle n_2 \rangle + \langle n \rangle} \gtrsim \frac{|n_1||n_2|(1 - \cos \theta)}{\langle n \rangle}
\]

where \(\theta = \angle(n_1, n_2) \in [0, \pi]\) is the angle between \(n_1\) and \(n_2\). When \(1 - \cos \theta \gtrsim 1\), we can proceed as in (3.20). Next, consider the case \(1 - \cos \theta \sim \theta^2 \ll 1\). Since \(n = n_1 + n_2\), we see that the angle \(\angle(n, n_2)\) between \(n\) and \(n_2\) is smaller than \(\theta = \angle(n_1, n_2)\) in this case.\(^{20}\) Hence, with \(|n_1| \gtrsim |n|\), we can repeat the computation in (3.21) and obtain the same bound. This concludes the proof of (3.8) by choosing \(\delta > 0\) sufficiently small.

Next, we briefly discuss the difference estimate (3.9). Let \(0 \leq t_2 \leq t_1 \leq T\). We need to estimate

\[
\mathbb{E} [\hat{\varphi}(n,t_1) - \hat{\varphi}(n,t_2)]^2 = \mathbb{E} [\hat{\varphi}(n,t_1) - \hat{\varphi}(n,t_2) \hat{\varphi}(n,t_1)] - \mathbb{E} [\hat{\varphi}(n,t_1) - \hat{\varphi}(n,t_2)]^2.
\]

From (3.7), we have

\[
\hat{\varphi}(n,t_1) - \hat{\varphi}(n,t_2) = \int_0^{t_1} \sin((t_1 - t')\langle n \rangle)\hat{\varphi}(n,t')dt' + \int_0^{t_2} \sin((t_2 - t')\langle n \rangle)\hat{\varphi}(n,t')dt'.
\]

We crudely estimate (3.24) by using (3.25), (3.6), and the mean value theorem to control the difference. As a result, we have

\[
\mathbb{E} [\hat{\varphi}(n,t_1) - \hat{\varphi}(n,t_2)]^2 \lesssim C(T) \langle n \rangle^{-2} |t_1 - t_2|.
\]

\(^{20}\)Form a triangle with three vectors \(n, n_1,\) and \(n_2\) with \(n\) and \(n_2\) sharing a common base point such that \(n = n_1 + n_2\). Then, the angle \(\angle(n, n_2)\) is an exterior angle to this triangle and thus we have \(\angle(n_1, n_2) = \angle(n, n_2) + \angle(-n, -n_1) \leq \angle(n, n_2)\).
By interpolating (3.8) and (3.26), we obtain (3.9) for some small $\sigma \in (0, 1)$.

This completes the proof of Proposition 1.6. \hfill $\Box$

**Remark 3.3.** In Cases 2 and 3, we separately estimated the contributions from (i) $1 - \cos \theta \gtrsim 1$ and (ii) $1 - \cos \theta \ll 1$. Note that these correspond to the time non-resonant and (nearly) time resonant case in the dispersive PDE terminology. In the time resonant case (ii), there was no gain from time integration and thus we needed to exploit the smallness of the set (i.e. the cone $C$) for the time resonant case by observing that the time resonance is caused by the parallel interaction of waves, i.e. $n, n_1$, and $n_2$ (close to) being parallel. A need for such a geometric consideration is one difference between the study of dispersive equations from that of parabolic equations.

4. **On the stochastic terms, Part II**

In this section, we study the regularity property of the resonant product $\hat{\varphi}$ defined in (1.26) (Proposition 1.8). From (1.22) and the definition of the Littlewood-Paley projector $\mathcal{F}(P_j f)(n) = \varphi_j(n) \hat{f}(n)$, we have

$$\hat{\varphi}(n, t) = \sum_{n=n_1+n_2+n_3} \sum_{|j-k| \leq 2} \varphi_j(n_1 + n_2)\varphi_k(n_3)$$

$$\times \int_0^t \sin((t-t')\langle n_1 + n_2 \rangle) \langle n_1, t' \rangle \hat{\tau}(n_2, t') dt' \cdot \hat{\tau}(n_3, t)$$

$$+ \sum_{n_1 \in \mathbb{Z}^3} \sum_{|k| \leq 2} \varphi_k(n_3) \int_0^t \sin(t-t') \cdot (|\hat{\tau}(n_1, t')|^2 - \sigma_{n_3}(t')) dt' \cdot \hat{\tau}(n, t)$$

$$=: \mathcal{R}_1(n, t) + \mathcal{R}_2(n, t).$$

For simplicity of notation, however, we write

$$\mathcal{R}_1(n, t) = \sum_{n=n_1+n_2+n_3} \int_0^t \sin((t-t')\langle n_1 + n_2 \rangle) \langle n_1, t' \rangle \hat{\tau}(n_2, t') dt' \cdot \hat{\tau}(n_3, t),$$

$$\mathcal{R}_2(n, t) = \sum_{n_1 \in \mathbb{Z}^3} 1_{|n| \sim 1} \int_0^t \sin(t-t') \cdot (|\hat{\tau}(n_1, t')|^2 - \sigma_{n_1}(t')) dt' \cdot \hat{\tau}(n, t),$$

where the conditions $|n_1 + n_2| \sim |n_3|$ in the first term and $|n| \sim 1$ in the second term signify the resonant product $\hat{\varphi}$. The second term $\mathcal{R}_2$ in (4.1) corresponds to the contribution from $n_1 + n_2 = 0$ and is already renormalized from the Wick renormalization: $t^2 \sim \nu$. Using (3.11) and Lemma 2.6, it is easy to see that $\mathcal{R}_2 \in C(\mathbb{R}^+; C^\infty(\mathbb{T}^3))$ almost surely, since $|n| \sim 1$.

In the following, our main goal is to show

$$\mathbb{E}[|\mathcal{R}_1(n, t)|^2] \leq C(t)\langle n \rangle^{-3+}.$$  (4.2)
Then, Lemma 2.6 allows us to conclude that $\mathcal{R}_1(t) \in W^{0,-\infty}(\mathbb{T}^3)$ almost surely. We decompose $\mathcal{R}_1$ as

$$
\hat{\mathcal{R}}_1(n,t) = \sum_{n= n_1 + n_2 + n_3 \atop |n_1| + |n_2| + |n_3|} \int_0^t \frac{\sin((t - t')(n_1 + n_2))}{(n_1 + n_2)} \hat{\gamma}(n_1, t') \hat{\gamma}(n_2, t') dt' \cdot \hat{\gamma}(n_3, t)
$$

$$
+ 2 \int_0^t \hat{\gamma}(n, t') \left( \sum_{n_2 \in \mathbb{Z}^3 \atop |n_2| \sim |n|} \frac{\sin((t - t')(n + n_2))}{n + n_2} \sigma_{n_2}(t, t') \right) dt'
$$

$$
= \hat{\mathcal{R}}_{11}(n, t) + \hat{\mathcal{R}}_{12}(n, t) + \hat{\mathcal{R}}_{13}(n, t) + \hat{\mathcal{R}}_{14}(n, t).
$$

(4.3)

Here, the second term $\mathcal{R}_{12}$ corresponds to the “renormalized” contribution from $n_1 + n_3 = 0$ or $n_2 + n_3 = 0$, while the fourth term corresponds to the contribution from $n_1 = n_2 = n = -n_3$.

From (3.1), we have

$$
\mathbb{E}[|\hat{\mathcal{R}}_{14}(n, t)|^2] \leq C(t)\langle n \rangle^{-8},
$$

satisfying (4.2). Under $|n + n_2| \sim |n_2|$, we have $|n_2| \geq |n|$. Then, using a variant of (3.11), we obtain

$$
\mathbb{E}[|\hat{\mathcal{R}}_{12}(n, t)|^2] \leq C(t) \sum_{n_2 \in \mathbb{Z}^3 \atop |n_2| \sim |n|} \frac{1}{\langle n \rangle^2\langle n_2 \rangle^6} \lesssim \langle n \rangle^{-5},
$$

satisfying (4.2).

Given $n \in \mathbb{Z}^3$, define $\text{NR}(n)$ by

$$
\text{NR}(n) = \{(n_1, n_2, n_3) \in \mathbb{Z}^3 : n = n_1 + n_2 + n_3, \ |n_1 + n_2| \sim |n_3|,
$$

$$
(n_1 + n_2)(n_2 + n_3)(n_3 + n_1) \neq 0\}.
$$

Then, with a shorthand notation $n_{ij} = n_i + n_j$, we have

$$
\mathbb{E}[|\hat{\mathcal{R}}_{11}(n, t)|^2]
$$

$$
= \mathbb{E} \left[ \sum_{(n_1, n_2, n_3) \in \text{NR}(n)} \int_0^t \frac{\sin((t - t_1)\langle n_1 \rangle)}{\langle n_1 \rangle} \hat{\gamma}(n_1, t_1) \hat{\gamma}(n_2, t_1) dt' \cdot \hat{\gamma}(n_3, t) \right]
$$

$$
\times \sum_{(n'_1, n'_2, n'_3) \in \text{NR}(n)} \int_0^t \frac{\sin((t - t_2)\langle n'_2 \rangle)}{\langle n'_2 \rangle} \hat{\gamma}(n'_1, t_2) \hat{\gamma}(n'_2, t_2) dt' \cdot \hat{\gamma}(n'_3, t) \right].
$$

In order to compute the expectation above, we need to take all possible pairings between $(n_1, n_2, n_3)$ and $(n'_1, n'_2, n'_3)$. By Jensen’s inequality, however, we see that it suffices to consider
the case \( n_j = n_j', j = 1, 2, 3 \). See the discussion on \( \gamma \) in Section 4 of [41]. See also Section 10 in [11]. Hence, by Wick’s theorem and (3.10), we have
\[
\mathbb{E}[|\tilde{R}_{11}(n, t)|^2] \lesssim \sum_{n = m + n_3}^{m + n_3 + n_3} \mathbb{E}[|\tilde{\gamma}(m, t)|^2] \mathbb{E}[|\tilde{\gamma}(n_3, t)|^2]
\]

From (3.2), (3.8), and Lemma 2.3 (ii),
\[
\frac{1}{(m)^4 - (n_3)^2} \leq C(t) \leq C(t) \langle n \rangle^{-3+},
\]

verifying (4.2). Note that in evaluating the last sum, we crucially used the fact that the product is a resonant product.

It remains to study the third term \( \tilde{R}_{13} \) on the right-hand side of (4.3). Let \( 0 \leq t_2 \leq t_1 \leq T \). Then, from (4.3) with (1.32), we have
\[
\mathbb{E}[|\tilde{R}_{13}(n, t)|^2] = 8 \sum_{k_0, k_1, k_2 \in \{1, 2\}} \int_0^t \int_0^{t_1} \sigma_n^{(k_0)}(t_1, t_2) \times \left[ \sum_{n_2 \in \mathbb{Z}^3} \frac{\sin((t - t_1)\langle n + n_2 \rangle)}{\langle n + n_2 \rangle} \sigma_n^{(k_1)}(t, t_1) \right] \times \left[ \sum_{n_2' \in \mathbb{Z}^3} \frac{\sin((t - t_2)\langle n + n_2' \rangle)}{\langle n + n_2' \rangle} \sigma_n^{(k_2)}(t, t_2) \right] dt_2 dt_1
\]

where \( \sigma_n(t, t') = \sigma_n^{(1)}(t, t') + \sigma_n^{(2)}(t, t') \) as in (3.14). In the following, we only consider the contribution from \((k_0, k_1, k_2) = (1, 1, 1)\) since the other cases follow in a similar (but easier) manner.

From (3.14), we have
\[
I^{(1,1,1)}(n, t) = \int_0^t \int_0^{t_1} \frac{\cos((t_1 - t_2)\langle n \rangle)}{(n)^2} \times \left[ \sum_{n_2 \in \mathbb{Z}^3} \frac{\sin((t - t_1)\langle n + n_2 \rangle)}{\langle n + n_2 \rangle} \cos((t_1 - t_2)\langle n_2 \rangle) \right] \times \left[ \sum_{n_2' \in \mathbb{Z}^3} \frac{\sin((t - t_2)\langle n + n_2' \rangle)}{\langle n + n_2' \rangle} \cos((t - t_2)\langle n_2' \rangle) \right] dt_2 dt_1
\]
\[
= -\frac{1}{32} \sum_{\varepsilon_j \in \{-1, 1\}} \sum_{n_2 \in \mathbb{Z}^3} \sum_{n_2' \in \mathbb{Z}^3} \sum_{|n_2| \neq |n_2'|} \sum_{|n_2| \neq |n_2'|} \frac{\varepsilon_1 \varepsilon_2 e^{it_1 \langle n \rangle + \frac{1}{2} \varepsilon_2 (n + n_2') + \frac{1}{2} \varepsilon_3 (n_2') + \frac{1}{2} \varepsilon_4 (n_2')}}{(n)^2 \langle n \rangle (n_2)^2 \langle n + n_2' \rangle (n_2')^2} \times \int_0^t t_1 e^{-it_1 \langle \tilde{n} \rangle} \int_0^{t_1} t_2 e^{-it_2 \langle \tilde{n} \rangle} dt_2 dt_1.
\]
where $\kappa_3(\bar{n})$ and $\kappa_3(\bar{n})$ are defined by
\[
\begin{align*}
\kappa_3(\bar{n}) &= \varepsilon_1(n + n_2) + \varepsilon_3(n_2) - \varepsilon_5(n), \\
\kappa_4(\bar{n}) &= \varepsilon_2(n + n_2) + \varepsilon_4(n_2) + \varepsilon_5(n).
\end{align*}
\tag{4.5}
\]
Under the constraint $|n + n_2| \sim |n_2|$ and $|n + n_2| \sim |n_2|$, we have $|n_2|, |n_2| \gtrsim |n|$. In the following, we also assume $|n_2| \gtrsim |n_2'|$.

We decompose $I^{(1,1,1)}(n, t)$ according to the value of $\bar{\varepsilon} = (\varepsilon_1, \ldots, \varepsilon_5) \in \{\pm 1\}^5$ and write
\[
I^{(1,1,1)}(n, t) = \sum_{\bar{\varepsilon} \in \{\pm 1\}^5} I^{(1,1,1)}_{\bar{\varepsilon}}(n, t).
\]
In the following, we study $I^{(1,1,1)}_{\bar{\varepsilon}}$ for each fixed $\bar{\varepsilon} \in \{\pm 1\}^5$. Note that the sum over $n_2$ and $n_2'$ in (4.4) are not absolutely convergent at a first glance. In many cases, we make use of dispersion (i.e., time oscillation) and show that they are indeed absolutely convergent. In Case 3 below, however, there is a subcase, where we show that the sum is only conditionally convergent. In this case, it is understood that the sum is first studied under the constraint $|n_2|, |n_2'| \leq N$ for some $N \geq 1$ and that the sum remains bounded in taking a limit $N \to \infty$. We do not mention this procedure in an explicit manner in the following.

By first integrating (4.4) in $t_1$ when $|\kappa_3(\bar{n})| \gtrsim 1$ and simply bounding the integral in (4.4) by $C(T)$ when $|\kappa_3(\bar{n})| < 1$, we have
\[
|I^{(1,1,1)}_{\bar{\varepsilon}}(n, t)| \leq \frac{C(T)}{(n)^{2-\delta}} \sum_{n_2 \in \mathbb{Z}^3} \frac{1}{(n + n_2)(n_2)^2(1 + |\kappa_3(\bar{n})|)} \times \sum_{n_2' \in \mathbb{Z}^3} \frac{1(|n_2| \gtrsim |n_2'|)}{(n + n_2')(n_2')^2}.
\tag{4.6}
\]

- **Case 1:** $(\varepsilon_1, \varepsilon_3, \varepsilon_5) = (\pm 1, \pm 1, \mp 1)$. In this case, it follows from (4.5) that $|\kappa_3(\bar{n})| \gtrsim |n_2|$. By writing $(1 + |\kappa_3(\bar{n})|)^{-1} \lesssim \langle n \rangle^{-1+2\delta} \langle n_2 \rangle^{-\delta} \langle n_2 \rangle^{-\delta}$ in (4.6) for sufficiently small $\delta > 0$ and applying Lemma 2.3, we obtain
\[
|I^{(1,1,1)}_{\bar{\varepsilon}}(n, t)| \leq C(T)n^{-3}.
\tag{4.7}
\]
- **Case 2:** $(\varepsilon_1, \varepsilon_3, \varepsilon_5) = (\pm 1, \pm 1, \pm 1)$. If $|n + n_2| \sim |n_2| \gg |n|$, then we have $|\kappa_3(\bar{n})| \gtrsim |n_2|$ and hence (4.7) holds as above. Otherwise, we have $|n + n_2| \sim |n_2| \sim |n|$. In this case, by $\langle n \rangle^{-2\delta} \lesssim \langle n_2 \rangle^{-\delta} \langle n_2 \rangle^{-\delta}$ for $\delta > 0$. Then, we have
\[
|I^{(1,1,1)}_{\bar{\varepsilon}}(n, t)| \leq \frac{C(T)}{(n)^{2-2\delta}} \sum_{n_2 \in \mathbb{Z}^3} \frac{1}{(n + n_2)(n_2)^{2+\delta}(1 + |\kappa_3(\bar{n})|)} \times \sum_{n_2' \in \mathbb{Z}^3} \frac{1(|n_2| \gtrsim |n_2'|)}{(n + n_2')(n_2')^{2+\delta}}
\leq \frac{C(T)}{(n)^{2-\delta}} \sum_{n_2 \in \mathbb{Z}^3} \frac{1}{(n + n_2)(n_2)^{2+\delta}(1 + |\kappa_3(\bar{n})|)}. \tag{4.8}
\]
We can now proceed as in Case 3 of the proof of Proposition 1.6 by replacing \((n, n_1, n_2)\) with \((n, n + n_2, -n_2)\). In particular, from (3.23), we have
\[
|\kappa_3(n)| \gtrsim |n_2| (1 - \cos \theta)
\] (4.9)
where \(\theta = \angle(n + n_2, -n_2) \in [0, \pi]\) is the angle between \(n + n_2\) and \(-n_2\). When \(1 - \cos \theta \gtrsim 1\), by summing over \(n_2\) in (4.8) with (4.9) and Lemma 2.3 we obtain (4.7).

Next, consider the case \(1 - \cos \theta \sim \theta^2 \ll 1\). Since \(n = (n + n_2) + (-n_2)\), we see that the angle \(\theta_0 = \angle(n, -n_2)\) between \(n\) and \(-n_2\) is smaller than \(\theta = \angle(n + n_2, -n_2)\) in this case. Moreover, we see that for fixed \(n \in \mathbb{Z}^3\), the range of possible \(-n_2\) with \(|n_2| \sim N_2\), dyadic \(N_2 \geq 1\), is constrained to a cone whose height is \(\sim N_2 \cos \theta_0 \sim N_2\) and the base disc of radius \(\sim N_2 \sin \theta_0 \lesssim N_2 \theta\).

Then, from (4.8) and (4.9) with \(|n + n_2| \sim |n_2| \sim |n|\), we have
\[
|I^{(1,1,1)}_\varepsilon(n, t)| \leq \frac{C(T)}{\langle n \rangle^{2-\delta}} \sum_{n_2 \sim \langle n \rangle} \frac{1}{N_2^{4+\delta} \theta^2 N_2^3 \theta^2} 
\]
\[
\leq C(T) \langle n \rangle^{-3+\delta},
\]
yielding (4.7).

- **Case 3**: \(\varepsilon_1 = -\varepsilon_3\). First, suppose that \(|n| \geq |n_2|^\gamma\) for some small \(\gamma > 0\) (to be chosen later).

Then, with \(\langle n \rangle^{-2\delta} \lesssim \langle n_2 \rangle^{-\gamma \delta} \langle n_2 \rangle^{-\gamma \delta}\) for \(\lambda > 0\), we can proceed as in Case 2 (but using the computation in Case 2 of the proof of Proposition 1.6 by replacing \((n, n_1, n_2)\) with \((n, n + n_2, -n_2)\) or \((n, -n_2, n + n_2)\)) and obtain
\[
|I^{(1,1,1)}_\varepsilon(n, t)| \leq \frac{C(T)}{\langle n \rangle^{2-2\delta}} \sum_{n_2 \in \mathbb{Z}^3 \atop |n + n_2| \sim |n_2|} \frac{1}{\langle n + n_2 \rangle \langle n_2 \rangle^{2+\gamma \delta} (1 + |\kappa_3(n)|)}
\]
\[
\times \sum_{n_2' \in \mathbb{Z}^3 \atop |n + n_2| \sim |n_2|} \frac{1_{\{n_2' \geq |n_2|\}}}{\langle n + n_2 \rangle \langle n_2' \rangle^{2+\gamma \delta}}
\]
\[
\leq C(T) \langle n \rangle^{-3+(2-\gamma)\delta},
\]
verifying (4.2) by choosing \(\delta > 0\) sufficiently small.

Next, we consider the case \(|n| \ll |n_2|^\gamma\). In this case, we are not able to prove absolute summability in (4.6) since \(\kappa_3(n)\) does not have any good lower bound, and thus we need to proceed more carefully. By writing out the contribution from the sum over \(n_2\) in (4.4) (namely, ignoring the sum over \(n_2'\)), we have
\[
\int_0^t t_1 e^{it_1 \varepsilon_3(n)} \sum_{n_2 \in \mathbb{Z}^3 \atop |n + n_2| \sim |n_2|} \sum_{n_2' \in \mathbb{Z}^3 \atop |n + n_2| \sim |n_2|} \sin((t - t_1) \langle n + n_2 - \langle n_2 \rangle \rangle) \frac{d\tau_1}{\langle n \rangle \langle n + n_2 \rangle \langle n_2 \rangle^2}.
\] (4.10)

By going back to the definition (1.22) of the resonant product \(\varphi\), we can write down the sum over \(n_2\) in (4.10) as
\[
\sum_{j \in \mathbb{N}_0} \sum_{n_2 \in \mathbb{Z}^3 \atop |n| \ll |n_2|} \varphi_j(n_2) \sum_{|k-j| \leq 2} \varphi_k(n + n_2),
\] (4.11)
While the sum over \(n\) as in (2.1). Thanks to the restriction \(|n| \ll |n_2|^\gamma\) with small \(\gamma > 0\), the sum in (4.11) is in fact given by

\[
\sum_{j \in \mathbb{N}_0} \sum_{n_2 \in \mathbb{Z}^3 \atop |n| \ll |n_2|^\gamma} \varphi_j(n_2). \tag{4.12}
\]

While the sum over \(n_2\) in (4.10) is not absolutely convergent, we do not expect to gain anything from the time integration in \(t_1\) in this case due to the lack of a good lower bound on \(\kappa_3(\bar{n})\). The reduction to (4.12), however, allows us to exploit the symmetry \(n_2 \leftrightarrow -n_2\) and the oscillatory nature of the sine kernel in (4.10).

By the Taylor remainder theorem, we have

\[
\Theta^\pm(n, n_2) := \langle n \pm n_2 \rangle - \langle n_2 \rangle = O \left( \frac{\langle n \rangle^2 \langle n_2 \rangle}{|n_2|^2} \right) \tag{4.13}
\]

Let \(\Lambda\) be the index set “\(\sim \mathbb{Z}^3/2\)” in (1.7). Then, with (4.13) and the mean value theorem, we have

\[
(4.10) = \int_0^t t_1 e^{it_1 \varepsilon_5(n)} \sum_{j \in \mathbb{N}_0} \sum_{n_2 \in \mathbb{Z}^3 \atop |n| \ll |n_2|^\gamma} \varphi_j(n_2) \frac{\sin((t-t_1)(\langle n+n_2 \rangle - \langle n_2 \rangle))}{\langle n \rangle^2 \langle n+n_2 \rangle \langle n_2 \rangle^2} dt_1
\]

\[
= \int_0^t t_1 e^{it_1 \varepsilon_5(n)} \sum_{j \in \mathbb{N}_0} \sum_{n_2 \in \Lambda \atop |n| \ll |n_2|^\gamma} \varphi_j(n_2) \frac{\langle n \rangle^2 \langle n+n_2 \rangle \langle n_2 \rangle^2}{\langle n \rangle^2 \langle n+n_2 \rangle \langle n_2 \rangle^2}
\]

\[
\times \left\{ \sin((t-t_1)(\langle n+n_2 \rangle - \langle n_2 \rangle)) + \sin((t-t_1)(\langle n-n_2 \rangle - \langle n_2 \rangle)) \right\} dt_1
\]

\[
= \int_0^t t_1 e^{it_1 \varepsilon_5(n)} \sum_{j \in \mathbb{N}_0} \sum_{n_2 \in \Lambda \atop |n| \ll |n_2|^\gamma} \varphi_j(n_2) \frac{\langle n \rangle^2 \langle n+n_2 \rangle \langle n_2 \rangle^2}{\langle n \rangle^2 \langle n+n_2 \rangle \langle n_2 \rangle^2}
\]

\[
\times \left\{ \sin \left( (t-t_1) \left( \left\langle \frac{n,n_2}{n_2} \right\rangle + \Theta^+ (n, n_2) \right) \right) + \sin \left( (t-t_1) \left( \left\langle \frac{n,n_2}{n_2} \right\rangle - \Theta^- (n, n_2) \right) \right) \right\} dt_1
\]

\[
\leq C(T) \sum_{j \in \mathbb{N}_0} \sum_{n_2 \in \Lambda \atop |n| \ll |n_2|^\gamma} \varphi_j(n_2) \frac{\langle n \rangle^{4\delta}}{\langle n \rangle^2 \langle n+n_2 \rangle \langle n_2 \rangle^2 \langle n_2 \rangle^{2\delta}}
\]

\[
\leq C(T) (n')^\delta \sum_{n_2 \in \Lambda \atop |n| \ll |n_2|^\gamma} \frac{1}{\langle n \rangle^{2-4\delta} \langle n_2 \rangle^{3+\delta}}
\]

for any \(\delta \in [0, \frac{1}{2}]\). Fix small \(\delta > 0\). By applying Lemma 2.3 to sum over \(n_2\) and \(n'\) and then using the condition \(|n| \ll |n_2|^\gamma\), we obtain

\[
|I_{\varepsilon}^{(1,1,1)}(n,t)| \leq C(T) \frac{1}{\langle n \rangle^{2-3\delta} \langle n \rangle^\delta} \leq C(T) \langle n \rangle^{-3}
\]

by choosing \(\gamma = \gamma(\delta) > 0\) sufficiently small. This proves (4.2).
Next, we briefly discuss the difference estimate. In view of Lemma 2.6, we need to show that there exists \( \sigma \in (0, 1) \) such that
\[
\mathbb{E} [ |\hat{R}_1(n, t_1) - \hat{R}_1(n, t_2)|^2 ] \leq C(T) \langle n \rangle^{-3+\sigma} |t_1 - t_2|^{\sigma}
\]
(D.14) for any \( n \in \mathbb{Z}^3, 0 \leq t, t_1, t_2 \leq T \) with \( 0 < |t_1 - t_2| < 1 \). As in (3.4), we need to estimate
\[
\mathbb{E} [ |\hat{R}_1(n, t_1) - \hat{R}_1(n, t_2)|^2 ] = \sum_{j=1}^{2} (-1)^{j+1} \mathbb{E} [ |(\hat{R}_1(n, t_1) - \hat{R}_1(n, t_2)) \hat{y}(n, t_j)|^2 ].
\]
(4.15) As for \( R_{11}, R_{12}, \) and \( R_{14} \) in (4.3), we can crudely estimate them and obtain
\[
\mathbb{E} [ |\hat{R}_{1j}(n, t_1) - \hat{R}_{1j}(n, t_2)|^2 ] \lesssim C(T) \langle n \rangle^{-3+} |t_1 - t_2|,
\]
(D.16) for \( j = 1, 2, 4 \), since the relevant summations are absolutely convergent. Then, (4.14) follows from interpolating (4.16) and
\[
\mathbb{E} [ |\hat{R}_{1j}(n, t_1) - \hat{R}_{1j}(n, t_2)|^2 ] \lesssim C(T) \langle n \rangle^{-3+}.
\]

It remains to discuss \( R_{13} \). In view of (4.4) and (4.15), we need to consider an expression like
\[
\int_0^{t_2} \int_0^{t_1} \frac{\cos((t_1 - t_2)\langle n \rangle)}{\langle n \rangle^2} \tau_2 \left[ \sum_{n_2 \in \mathbb{Z}^3} \frac{\sin((t - t_1)\langle n + n_2 \rangle) \cos((t - t_1)\langle n_2 \rangle)}{\langle n_2 \rangle^2} \tau_1 \right]_{t=t_2}^{t_1} \times \left[ \sum_{n_2' \in \mathbb{Z}^3} \frac{\sin((t_2 - t_2)\langle n + n_2' \rangle) \cos((t_2 - t_2)\langle n_2' \rangle)}{\langle n_2' \rangle^2} \tau_2 \right] d\tau_2 d\tau_1
\]
for \( 0 \leq t_2 \leq t_1 \leq T \). Then, by repeating the computations in Cases 1 - 3 above and applying the mean value theorem, we directly obtain (4.14). Note that some of the relevant summations are not absolutely convergent in this case and hence we can not proceed with a crude estimate and interpolation. Compare this with the parabolic setting. See Section 5 in [66].

This completes the proof of Proposition 1.8.

5. PARACONTROLLED OPERATORS

We first present the proof of Lemma 1.9 on the regularity of \( Z = (S(t)(X_0, X_1)) \oplus 1 \).

Proof of Lemma 1.9. Let \( H(t) = S(t)(X_0, X_1) \). Under \( n = n_1 + n_2 \) and \( |n_1| \sim |n_2| \), we have \( \langle n \rangle \lesssim \langle n_1 \rangle \sim \langle n_2 \rangle \). Then, it follows from Minkowski’s inequality, the Wiener chaos estimate (Lemma 2.5), independence of \( \hat{I}(n_2, t) \), and (3.2) that for any \( p \geq 2 \), we have
\[
\left\| |Z(t)| \right\|_{L^p(\Omega)} \leq \left\| \langle n \rangle^s \mathcal{F}_{n} \mathbb{E} (H \otimes t)(n, t) \right\|_{L^p(\Omega)} \leq p^{\frac{1}{2}} \left\| \langle n \rangle^s \mathcal{F}_{n} (H \otimes t)(n, t) \right\|_{L^2(\Omega)} \leq p^{\frac{1}{2}} \left( \sum_{n \in \mathbb{Z}^3} \langle n \rangle^{2s} \sum_{n_1 + n_2 = n \sim |n_2|} |\hat{H}(n_1, t)|^2 \mathbb{E} (|\hat{I}(n_2, t)|^2) \right)^{\frac{1}{2}} \lesssim p^{\frac{1}{2}} \left( \sum_{n \in \mathbb{Z}^3} \langle n \rangle^{2(s-s_1)} \sum_{n_1 \sim |n_2|} \langle n_1 \rangle^{2s_1} |\hat{H}(n_1, t)|^2 \right)^{\frac{1}{2}} \lesssim p^{\frac{1}{2}} \| (X_0, X_1) \|_{\nu^1}
\]
(5.1)
provided that $s < s_1 - \frac{1}{2}$. Fix $\varepsilon > 0$ small. Then, by writing
\[(H \otimes 1)(t_1) - (H \otimes 1)(t_2) = (H(t_1) \otimes (1(t_1) - 1(t_2))) + (H(t_1) - H(t_2)) \otimes 1(t_2)\]
for $0 \leq t_2 \leq t_1$, we can repeat the computation in (5.1). In particular, by (3.4) and the mean value theorem, we obtain
\[
\left\| (H \otimes 1)(t_1) - (H \otimes 1)(t_2) \right\|_{H^s} \leq C(t_2)p^\frac{1}{2}|t_1 - t_2|^\frac{1}{2} \left\| (X_0, X_1) \right\|_{H^{s_1}} + p^\frac{1}{2}\|H(t_1) - H(t_2)\|_{H^{s_1 - \frac{s}{2}}}
\]
provided that $s < s_1 - \frac{1}{2} - \frac{s}{2}$.

Therefore, by taking large $p = p(\varepsilon) \gg 1$, we conclude from
Kolmogorov’s continuity criterion ([6, Theorem 8.2]) that $Z$ belongs to $C([0, T]; H^{s_1 - \frac{1}{2} - \varepsilon}(\mathbb{T}^3))$ almost surely.

The remaining part of this section is devoted to studying the mapping properties of the paracontrolled operators $J^{(1)}_\otimes$ in (1.29) and $J_{\otimes, \otimes}$ in (1.30).

We first study the regularity property of the paracontrolled operator $J^{(1)}_\otimes$ defined in (1.29).

By writing out the frequency relation $|n_2|^\theta \lesssim |n_1| \ll |n_2|$ more carefully, we have
\[
J^{(1)}_\otimes(w)(t) = \sum_{n \in \mathbb{Z}^3} e_n \sum_{n = n_1 + n_2 \theta k + c_0 \leq j < k - 2} \varphi_j(n_1) \varphi_k(n_2) \times \int_0^t \sin((t - t')\langle n \rangle) \frac{\tilde{w}(n_1, t')}{\langle n \rangle} \tilde{t}(n_2, t')dt',
\]
where $c_0 \in \mathbb{R}$ is some fixed constant. In the following, we establish the mapping property of $J^{(1)}_\otimes$ in a deterministic manner by using a pathwise regularity of the stochastic convolution $1$.

Given $\Xi \in C(\mathbb{R}_+; W^{1, -\frac{1}{2} - \varepsilon}(\mathbb{T}^3))$ for some small $\varepsilon > 0$, define a paracontrolled operator $J^{(1)}_\otimes, \Xi$ by
\[
J^{(1)}_\otimes, \Xi(w)(t) := \sum_{n \in \mathbb{Z}^3} e_n \sum_{n = n_1 + n_2 \theta k + c_0 \leq j < k - 2} \varphi_j(n_1) \varphi_k(n_2) \times \int_0^t \sin((t - t')\langle n \rangle) \frac{\tilde{w}(n_1, t')}{\langle n \rangle} \tilde{\Xi}(n_2, t')dt'.
\]

Note that we have $J^{(1)}_\otimes = J^{(1)}_\otimes, 1$, i.e. with $\Xi = 1$.

**Lemma 5.1.** Let $0 < s_1 < \frac{1}{2}$ and $T > 0$. Then, given small $\theta > 0$, there exists small $\varepsilon = \varepsilon(s_1, \theta) > 0$ such that given $\Xi \in C(\mathbb{R}_+; W^{1, -\frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3))$, the paracontrolled operator $J^{(1)}_\otimes, \Xi$ defined in (5.3) belongs to the class:
\[
\mathcal{L}_2 = \mathcal{L}(C([0, T]; H^{s_1}(\mathbb{T}^3)) ; C([0, T]; H^{1, 2 + 2\varepsilon}(\mathbb{T}^3))).
\]

As a direct consequence of Lemma 5.1 with Lemma 3.1, we obtain the following corollary for the paracontrolled operator $J^{(1)}_\otimes$ defined in (1.29) and (5.2).

**Corollary 5.2.** Let $0 < s_1 < \frac{1}{2}$ and $T > 0$. Then, given small $\theta > 0$, there exists small $\varepsilon = \varepsilon(s_1, \theta) > 0$ such that the paracontrolled operator $J^{(1)}_\otimes$ defined in (1.29) belongs to $\mathcal{L}_2$ in (5.4) almost surely. Moreover, by letting $J^{(1), N}_\otimes$, $N \in \mathbb{N}$, denote the paracontrolled operator in (1.29) with $1$ replaced by the truncated stochastic convolution $1_N$ in (1.18), the truncated paracontrolled operator $J^{(1), N}_\otimes$ converges almost surely to $J^{(1)}_\otimes$ in $\mathcal{L}_2$. 
Proof of Lemma \[5.1\] Let \( s_1 > 0 \). Under \(|n_2|^\theta \lesssim |n_1| \ll |n_2|\) with \( n = n_1 + n_2 \), we have

\[
\langle n \rangle^{\frac{1}{2} + 2\varepsilon} \frac{1}{\langle n \rangle} \lesssim \langle n_1 \rangle^{\frac{1}{2} + \varepsilon} \langle n_2 \rangle^{-\frac{1}{2} - 2\varepsilon} \lesssim \langle n_1 \rangle^{s_1 - \varepsilon} \langle n_2 \rangle^{-\frac{1}{2} - 2\varepsilon} \tag{5.5}
\]

by choosing \( \varepsilon = \varepsilon(s_1, \theta) > 0 \) sufficiently small.

Let \( \tilde{w}_j(n_1, t') = \varphi_j(n_1)\tilde{w}(n_1, t') \) and \( \tilde{\Xi}_k(n_2, t') = \varphi_k(n_2)\tilde{\Xi}(n_2, t') \). Then, from (5.3) and (5.5), we have

\[
\|J^{(1)}_{\omega}(w)(t)\|_{H^{\frac{1}{2} + 2\varepsilon}} \lesssim \int_0^t \sum_{j, k=0}^\infty 2^{(s_1 - \varepsilon)j} 2^{-\frac{1}{2} - 2\varepsilon}k \bigg\| \tilde{w}_j(n_1, t') \tilde{\Xi}_k(n_2, t') \bigg\|_\ell^2 \leq \int_0^t \sum_{j, k=0}^\infty 2^{(s_1 - \varepsilon)j} 2^{-\frac{1}{2} - 2\varepsilon}k \|w_j(t')\|_{L^2} \|\Xi_k(t')\|_{L^2} dt'.
\]

Then, by summing over dyadic blocks and applying the trivial embedding (2.5), we obtain

\[
\|J^{(1)}_{\omega}(w)(t)\|_{H^{\frac{1}{2} + 2\varepsilon}} \lesssim T \|w\|_{L^\infty_t H^{\frac{1}{2}} \|\Xi\|_{L^\infty_t B^{-\frac{1}{2} - 2\varepsilon}_\infty}_x} \lesssim T \|w\|_{L^\infty_t H^{\frac{1}{2}} \|\Xi\|_{L^\infty_t W^{-\frac{1}{2} - \varepsilon}_\infty}_x}.
\]

for any \( t \in [0, T] \). The continuity in time of \( J^{(1)}_{\omega}(w) \) follows from modifying the computation above as in the previous subsections. We omit the details. \( \Box \)

Finally, we present the proof of Proposition \[1.11\] on the paracontrolled operator \( J_{\omega, \omega} \) in (1.30). By writing out the frequency relations more carefully as in (5.2), we have

\[
J_{\omega, \omega}(w)(t) = \sum_{n \in \mathbb{Z}^d} e_n \int_0^t \sum_{j=0}^\infty \sum_{n_1 \in \mathbb{Z}^d} \varphi_j(n_1)\tilde{w}(n_1, t')A_{n, n_1}(t, t')dt',
\tag{5.6}
\]

where \( A_{n, n_1}(t, t') \) is given by

\[
A_{n, n_1}(t, t') = 1_{[0, t]}(t') \sum_{k=0}^\infty \sum_{j=0}^\infty \sum_{m=0}^\infty \sum_{n-n_1=n_2+n_3} \varphi_k(n_2)\varphi_j(n_1 + n_2)\varphi_m(n_3) \times \frac{\sin((t - t')(n_1 + n_2))}{(n_1 + n_2)} \tilde{\gamma}(n_2, t') \tilde{\gamma}(n_3, t).
\tag{5.7}
\]

For ease of notation, however, we simply use (1.30) and (1.31) in the following, with the understanding that the frequency relations \(|n_1| \ll |n_2|^\theta\) and \(|n_1 + n_2| \sim |n_3|\) are indeed characterized by the use of smooth frequency cutoff functions as in (5.6) and (5.7). Moreover, we drop the cutoff function \( 1_{[0, t]}(t') \) in the following with the understanding that \( 0 \leq t' \leq t \).

Proof of Proposition \[1.11\] We separately consider the contributions to \( J_{\omega, \omega} \) from \( A_{n, n_1}^{(1)} \) and \( A_{n, n_1}^{(2)} \) defined in (1.33) and denote them respectively \( J_{\omega, \omega}^{(1)}(w) \) and \( J_{\omega, \omega}^{(2)}(w) \).
Given dyadic \( N_2 \geq 1 \), let \( A_{n,n_1}^{(1)}(t,t') \) be the contribution to \( A_{n,n_1}^{(1)}(t,t') \) from \( \{ |n_2| \sim N_2 \} \) \footnote{More precisely speaking, \( A_{n,n_1}^{(1)}(t,t') \) denotes the contribution in \( 5.7 \) from \( 2^k \sim N_2 \).} Fix \( 0 \leq t \leq T \). Then, from (1.30) and (1.33), we have

\[
\| \mathcal{T}_{\mathcal{G},G}^{(1)}(w(t)) \|_{H^{s_2-1}} \leq \left\| \int_0^t \langle n \rangle^{s_2-1} \sum_{n_1 \in \mathbb{Z}^3} \hat{w}(n_1,t') A_{n,n_1}^{(1)}(t,t') dt' \right\|_{L^2_t}
\]

\[
\lesssim \frac{T^{\frac{1}{2}}}{(t,t')} \| w \|_{L^\infty_t L^2_x} \left\| \langle n \rangle^{s_2-1} A_{n,n_1}^{(1)}(t,t') \right\|_{L^2_t([0,T];\ell^2_{n_1})}
\]

\[
\lesssim \frac{T^{\frac{1}{2}}}{(t,t')} \| w \|_{L^\infty_t L^2_x} \sum_{\text{dyadic } n_2 \geq 1} \left\| \langle n \rangle^{s_2-1} A_{n,n_1}^{(1)}(t,t') \right\|_{L^2_t([0,T];\ell^2_{n_1})}
\]

\[
\lesssim \frac{T^{\frac{1}{2}}}{(t,t')} \| w \|_{L^\infty_t L^2_x} \| A^{(1)}(t,\cdot) \|_{A(T)},
\]

where we introduced the norm:

\[
\| A^{(1)}(t,\cdot) \|_{A(T)} := \left( \sum_{\text{dyadic } n_2 \geq 1} N_2^{\frac{1}{2}} \left\| \langle n \rangle^{s_2-1} A_{n,n_1}^{(1)}(t,t') \right\|_{L^2_t([0,T];\ell^2_{n_1})}^2 \right)^{\frac{1}{2}}.
\]

**Remark 5.3.** For fixed \( t,t' \in [0,T] \), set \( \mathcal{T}_{t,t'}(f) = \sum_{n_1 \in \mathbb{Z}^3} \hat{f}(n_1) A_{n,n_1}(t,t') e_n \). Then, the expression \( \| \langle n \rangle^{s_2-1} A_{n,n_1}^{(1)}(t,t') \|_{\ell^2_{n_1}} \) is nothing but the Hilbert-Schmidt norm of the operator \( \mathcal{T}_{t,t'} \) from \( L^2(\mathbb{T}^3) \) into \( H^{s_2-1}(\mathbb{T}^3) \). Recalling that the Hilbert-Schmidt norm of a given operator controls its operator norm, it is natural to work with the \( A(T) \)-norm of \( A^{(1)}(t,\cdot) \) defined above (which is conveniently modified to carry out analysis on each dyadic block \( \{ |n_2| \sim N_2 \} \)).

By a similar argument, we obtain

\[
\| \mathcal{T}_{\mathcal{G},G}^{(1)}(w(t_1)) - \mathcal{T}_{\mathcal{G},G}^{(1)}(w(t_2)) \|_{H^{s_2-1}} \leq |t_1 - t_2|^\frac{1}{2} \| w \|_{L^\infty_t L^2_x} \| A^{(1)}(t_1,\cdot) \|_{A(T)}
\]

\[
+ T^\frac{1}{2} \| w \|_{L^\infty_t L^2_x} \| A^{(1)}(t_1,\cdot) - A^{(1)}(s_2,\cdot) \|_{A(T)}
\]

for \( t_1, t_2 \in [0,T] \).

We now show that the random process \( t \mapsto A^{(1)}(t,\cdot) \) has almost surely continuous trajectories (in \( t \)) with respect to the Banach space generated by the norm \( \| \cdot \|_{A(T)} \). In order to do so, we apply Kolmogorov’s continuity criterion and we need, as usual, to evaluate sufficiently high moments of the random variable \( A^{(1)}(t_1,\cdot) - A^{(1)}(t_2,\cdot) \) with \( t_1, t_2 \in [0,T] \).

Note that the conditions \( |n_1| \ll |n_2|^{\theta} \) for some small \( \theta > 0 \) and \( |n_1 + n_2| \sim |n_3| \) imply \( |n_2| \sim |n_3| \gg |n_1| \). Moreover, with the condition \( n - n_1 = n_2 + n_3 \), we have \( |n_2| \sim |n_3| \gtrsim |n_1| \).
Then, with (1.32), we have

\[
\mathbb{E}\left[\|A_{n,n_1,N_2}^{(1)}(t,t')\|^2_{L^2_p([0,T])}\right] \\
\leq \left\| \sum_{n-n_1=n_2+n_3} \frac{|\sin((t-t')(n_1+n_2))|^2}{(n_1+n_2)^2} \mathbb{E}\left[|\tilde{v}(n_2,t')\tilde{v}(n_3,t)|^2\right] \right\|^2_{L^2_p([0,T])} \\
+ \left\| \sum_{n_2 \in \mathbb{Z}^3} \frac{|\sin((t-t')(n+n_2))|^2}{(n+n_2)^2} \mathbb{E}\left[|\tilde{v}(n_2,t')\tilde{v}(-n_2,t) - \sigma_{n_2}(t,t')|^2\right] \right\|^2_{L^2_p([0,T])} \\
\lesssim TN_2^{-3}1_{|n_1| \ll N_2^2}1_{|n| \ll N_2}.
\] (5.10)

Therefore, we obtain

\[
\mathbb{E}\left[\|A^{(1)}(t, \cdot)\|^2_{A(T)}\right] = \sum_{N_2 \geq 1} N_2^\delta \sum_{n,n_1} \langle n \rangle^{2s_2-2} \mathbb{E}\left[\|A_{n,n_1,N_2}^{(1)}(t,t')\|^2_{L^2_p([0,T])}\right] \\
\leq \sum_{N_2 \geq 1} N_2^{\delta-3} \sum_{n,n_1 \in \mathbb{Z}^3} \langle n \rangle^{2s_2-2} 1_{|n_1| \ll N_2^2} 1_{|n| \ll N_2} \\
\leq \sum_{N_2 \geq 1} N_2^{\delta+3\theta+2s_2-2} < \infty
\] (5.11)

by choosing \( \delta = \delta(s_2) > 0 \) and \( \theta = \theta(s_2) > 0 \) sufficiently small since \( s_2 < 1 \).

From (1.33), we have

\[
A_{n,n_1}^{(1)}(t_1,t') - A_{n,n_1}^{(1)}(t_2,t') \\
= \sum_{n-n_1=n_2+n_3} \frac{\sin((t_1-t')(n_1+n_2)) - \sin((t_2-t')(n_1+n_2))}{(n_1+n_2)} B_{n_2,n_3}(t_1,t')' \\
+ \sum_{n-n_1=n_2+n_3} \frac{\sin((t_2-t')(n_1+n_2))}{(n_1+n_2)} \left( B_{n_2,n_3}(t_1,t') - B_{n_2,n_3}(t_2,t') \right)
\] (5.12)

where \( B_{n_2,n_3}(t,t') = \tilde{v}(n_2,t')\tilde{v}(n_3,t) - 1_{n_2+n_3=0} \cdot \sigma_{n_2}(t,t') \). Arguing as in (5.10) and (5.11), we obtain

\[
\mathbb{E}\left[\|A^{(1)}(t_1, \cdot) - A^{(1)}(t_2, \cdot)\|^2_{A(T)}\right] \lesssim |t_1 - t_2|^{\sigma},
\]
for some small \( \sigma > 0 \). Indeed, the first term on the right-hand side of (5.12) can be controlled by the mean value theorem, creating an additional factor of \( \langle n_1 + n_2 \rangle^\sigma |t_1 - t_2|^{\sigma} \). On the other
hand, by writing

\[ B_{n_2,n_3}(t_1,t') - B_{n_2,n_3}(t_2,t') = \hat{\gamma}(n_2,t')\hat{\gamma}(n_3,t_1) - \hat{\gamma}(n_3,t_2) \]

\[ - \mathbb{E}\left[ \hat{\gamma}(n_2,t') \left( \hat{\gamma}(-n_2,t_1) - \hat{\gamma}(-n_2,t_2) \right) \right] \]

\[ - 1_{n_2+n_3=0}\left\{ \sigma_{n_2}(t_1,t') - \sigma_{n_2}(t_2,t') \right\}, \]

we can apply (3.3) and the mean value theorem to create \([t_1 - t_2]^\sigma\) at the expense of losing a small power in \(n_2\) or \(n_3\).

Finally, note that \(A_{n_1}(t)\) is a homogenous Wiener chaos of order 2. Therefore by Minkowski's inequality and the Wiener chaos estimate (Lemma 2.5), we obtain

\[ \mathbb{E}\left[ \|A^{(1)}(t_1,\cdot) - A^{(1)}(t_2,\cdot)\|^p_{A(T)} \right] \lesssim p^p |t_1 - t_2|^{\sigma_p}, \]

for any \(p \geq 2\). Finally, by Kolmogorov's continuity criterion, we conclude that

\[ \|A^{(1)}(t_1,\cdot) - A^{(1)}(t_2,\cdot)\|_{A(T)} \leq C(\omega)|t_1 - t_2|^{\sigma_{-}}, \]  

(5.13)

for all \(t_1, t_2 \in [0,T]\), where the constant \(C = C(\omega)\) lies in \(L^p(\Omega)\) for some large \(p \gg 1\). From (5.9) and (5.13), we then deduce the required almost sure continuity for \(A^{(1)}(\omega)\).

Next, we consider the contribution from \(A_{n_1,n_2}(t,t')\) in (1.33). This part is entirely deterministic. Since \(A_{n_1,n_2}(t,t') = 0\) unless \(n = n_1\), we only consider \(A_{n,n}(t,t')\). In view of (3.14), we decompose \(A_{n,n}(t,t')\) as

\[ A_{n,n}(t,t') = t' \sum_{\substack{n \in \mathbb{Z}^3 \setminus \{n \mid |n| \ll |n_2|\}^p}} \frac{\sin((t-t')\langle n + n_2 \rangle \cos((t-t')\langle n \rangle)}{\langle n + n_2 \rangle^2} \]

\[ + \sum_{\substack{n \in \mathbb{Z}^3 \setminus \{n \mid |n| \ll |n_2|\}^p}} \frac{\sin((t-t')\langle n + n_2 \rangle \rangle\langle n + n_2 \rangle)}{4\langle n + n_2 \rangle^2} \cdot O\left( \frac{1}{\langle n_2 \rangle^3} \right). \]

\[ = t' \sum_{\substack{n \in \mathbb{Z}^3 \setminus \{n \mid |n| \ll |n_2|\}^p}} \frac{\sin((t-t')\langle n + n_2 \rangle + \langle n_2 \rangle)}{4\langle n + n_2 \rangle^2} \]

\[ + t' \sum_{\substack{n \in \mathbb{Z}^3 \setminus \{n \mid |n| \ll |n_2|\}^p}} \frac{\sin((t-t')\langle n + n_2 \rangle - \langle n_2 \rangle)}{4\langle n + n_2 \rangle^2} \]

\[ + \sum_{\substack{n \in \mathbb{Z}^3 \setminus \{n \mid |n| \ll |n_2|\}^p}} \frac{\sin((t-t')\langle n + n_2 \rangle)}{\langle n + n_2 \rangle} \cdot O\left( \frac{1}{\langle n_2 \rangle^3} \right), \]

\[ =: A_n^{(3)}(t,t') + A_n^{(4)}(t,t') + A_n^{(5)}(t,t'). \]  

(5.14)

We will show that

\[ \|n^{-\epsilon} A_n^{(j)}(t,t')\|_{L^p(\mathbb{Z}^3)} \leq C(T) \]

(5.15)
for any \( \varepsilon > 0, 0 \leq t' \leq t \leq T \), and \( j = 4, 5 \). Then, by denoting by \( J^{(j)}_{\Theta,\Theta}(w) \) the contribution to \( J_{\Theta,\Theta}(w) \) from \( I_{n=n_1} \cdot A_n^{(j)} \), it follows from (1.30) and (5.15) that

\[
\|J^{(j)}_{\Theta,\Theta}(w)(t)\|_{H^{s_2} L^2} \lesssim \left\| \int_0^t \frac{1}{(n)^{1-s_2}} \tilde{w}(n, t') A_n^{(j)}(t, t') dt' \right\|_{L^{\infty}_t L^2_n} \\
\lesssim T \|w\|_{L^\infty_t L^2_n} \left\| \frac{1}{(n)^{1-s_2}} A_n^{(j)}(t, t') \right\|_{L^{\infty}_t, \Theta([0,T], L^\infty_n)} \\
\lesssim C(T) \|w\|_{L^\infty_t L^2_n}
\]  

(5.16)

for \( t \in [0,T] \) and \( j = 4, 5 \), provided that \( s_2 < 1 \). The continuity in time of \( J^{(j)}_{\Theta,\Theta}(w)(t) \) follows from a similar argument.

By noting that \( \langle n + n_2 \rangle \sim \langle n_2 \rangle \gg \langle n \rangle \) under \( |n| \ll |n_2|^{\theta} \), we see that (5.15) is easily verified for \( j = 5 \). On the other hand, the sum for \( A^{(4)}_n(t, t') \) is not absolutely convergent. As in Case 3 in Section 4, we exploit the symmetry \( n_2 \leftrightarrow -n_2 \) and the oscillatory nature of the sine kernel. With (4.13) and the mean value theorem, we have

\[
A^{(4)}_n(t, t') = t' \sum_{n_2 \in \Lambda, |n| \ll |n_2|^{\theta}} \frac{\sin((t - t')(\langle n + n_2 \rangle - \langle n_2 \rangle)) + \sin((t - t')(\langle n - n_2 \rangle - \langle n_2 \rangle))}{4 \langle n + n_2 \rangle \langle n_2 \rangle^2} \\
- \sum_{n_2 \in \Lambda, |n| \ll |n_2|^{\theta}} \frac{\sin((t - t')(\langle n - n_2 \rangle - \langle n_2 \rangle))}{4 \langle n_2 \rangle^2} \left( \frac{1}{\langle n + n_2 \rangle} - \frac{1}{\langle n - n_2 \rangle} \right) \\
+ \sum_{n_2 \in \Lambda, |n| \ll |n_2|^{\theta}} \frac{1}{4 \langle n + n_2 \rangle \langle n_2 \rangle^2} \left\{ \sin \left( (t - t') \left( \frac{\langle n_2 \rangle}{\langle n_2 \rangle} + \Theta^+(n, n_2) \right) \right) \\
- \sin \left( (t - t') \left( \frac{\langle n \rangle}{\langle n_2 \rangle} - \Theta^-(n, n_2) \right) \right) \right\} \\
+ O \left( \sum_{n_2 \in \Lambda, |n| \ll |n_2|^{\theta}} \frac{\langle n \rangle}{\langle n_2 \rangle^4} \right) \\
\lesssim \sum_{n_2 \in \Lambda, |n| \ll |n_2|^{\theta}} \frac{1}{\langle n + n_2 \rangle \langle n_2 \rangle^2 \langle n_2 \rangle^2} + O(1) \\
\lesssim \langle n \rangle^\delta
\]

for any \( \delta \in (0, 1] \). This proves (5.15) and hence (5.16) for \( j = 4 \).

It remains to consider \( A^{(3)}_n(t, t') \). For this term, there is no internal cancellation structure and we need to make use of its fast oscillation by directly studying \( J^{(3)}_{\Theta,\Theta}(w) \). From (1.30) and (5.14),
we have
\[ \| \mathcal{J}^{(3)}_{\Xi_{\langle n, n \rangle}}(w)(t) \|_{H^{s_2-1}} \lesssim \sum_{\varepsilon_1 \in \{-1, 1\}} \left\| e^{i \varepsilon_1 t'(n+n_2)+(n_2)} \frac{1}{\langle n \rangle} \int_0^t \hat{w}(n, t') e^{-i \varepsilon_1 t'(n+n_2)+(n_2)} \langle n+n_2 \rangle \langle n_2 \rangle^2 \, dt' \right\|_{L^1_{n, t}}. \]  
\hspace{1cm} (5.17)

Integrating by parts, we have
\[ \int_0^t \hat{w}(n, t') \frac{1}{\langle n \rangle} \int_0^t \hat{w}(n, t') e^{-i \varepsilon_1 t'(n+n_2)+(n_2)} \langle n+n_2 \rangle \langle n_2 \rangle^2 \, dt' \]
\[ = \frac{1}{\langle n \rangle} \int_0^t \hat{w}(n, t) e^{-i \varepsilon_1 t(n+n_2)+(n_2)} \]
\[ \times \left\{ \hat{w}(n, t) + t' \partial_t \hat{w}(n, t') \right\} e^{-i \varepsilon_1 t'(n+n_2)+(n_2)} \, dt' \]  
\hspace{1cm} (5.18)

Hence, from (5.17) and (5.18), we obtain
\[ \| \mathcal{J}^{(3)}_{\Xi_{\langle n, n \rangle}}(w)(t) \|_{H^{s_2-1}} \lesssim \sum_{n_2 \in \mathbb{Z}^3} \langle n_2 \rangle^{4-(s_2 + \varepsilon)} \left( \|w\|_{L^\infty_T H_x^{s_1-1, \varepsilon}} + \|\partial_t w\|_{L^\infty_T H_x^{s_1-1, \varepsilon}} \right) \]
\[ \lesssim \|w\|_{L^\infty_T H_x^{s_1-1}} + \|\partial_t w\|_{L^\infty_T H_x^{s_1-1}} \]
for some small \( \varepsilon > 0 \). The continuity in time of \( \mathcal{J}^{(3)}_{\Xi_{\langle n, n \rangle}}(w)(t) \) follows from a similar argument.

This completes the proof of Proposition 1.11.

\[ \square \]

6. Proof of Theorem 1.12

We present now the proof of Theorem 1.12. In the following, we assume that \( 0 < s_1 < s_2 < 1 \). Recall that (8, 3) and (4, 4) are \( \frac{1}{4} \)-admissible and \( \frac{1}{4} \)-admissible, respectively. Given \( 0 < T \leq 1 \), we define \( X^{s_1}_T \) (and \( Y^{s_2}_T \)) as the intersection of the energy spaces of regularity \( s_1 \) (and \( s_2 \), respectively) and the Strichartz space:
\[ X^{s_1}_T = C([0, T]; H^{s_1} (\mathbb{T}^3)) \cap C^1([0, T]; H^{s_1-1} (\mathbb{T}^3)) \cap L^8([0, T]; W^{s_1-\frac{1}{4}, \frac{3}{4}} (\mathbb{T}^3)), \]
\[ Y^{s_2}_T = C([0, T]; H^{s_2} (\mathbb{T}^3)) \cap C^1([0, T]; H^{s_2-1} (\mathbb{T}^3)) \cap L^4([0, T]; W^{s_2-\frac{1}{4}, 4} (\mathbb{T}^3)) \]  
\hspace{1cm} (6.1)

and set
\[ Z^{s_1, s_2}_T = X^{s_1}_T \times Y^{s_2}_T. \]

Let \( \Phi = (\Phi_1, \Phi_2) \) be as in (1.39) with the enhanced data set \( \Xi \) in (1.37) belonging to \( X^{s_1, s_2, \varepsilon}_T \) for some small \( \varepsilon = \varepsilon(s_1, s_2) > 0 \). By the Strichartz estimates (Lemma 2.4), the paraproduct estimate (Lemma 2.1), and the regularity assumptions on \( \mathcal{T} \) and \( \mathcal{Y} \), we have
\[ \| \Phi_1 (X, Y) \|_{X^{s_1}_T} \lesssim \|(X_0, X_1)\|_{\mathcal{H}^{s_1}} + \|(X + Y - \mathcal{Y}) \mathcal{T}\|_{L^1_T H^{s_1-1}} \]
\[ \lesssim \|(X_0, X_1)\|_{\mathcal{H}^{s_1}} + T \|(X + Y - \mathcal{Y}) \mathcal{T}\|_{L^\infty_T L^2_x} \]
\[ \lesssim \|(X_0, X_1)\|_{\mathcal{H}^{s_1}} + T \|(X, Y)\|_{Z^{s_1, s_2}_T} \]  
\hspace{1cm} (6.2)
provided that $s_1 - 1 < -\frac{1}{2} - \varepsilon$, namely $s_1 < \frac{1}{2}$. Similarly, by Lemmas 2.4 and 2.1 with the regularity assumption on the data set $\Xi$ in (1.37) and Corollary 5.2, we have

$$
\left\| S(t')(Y_0, Y_1) - \int_0^t \frac{\sin((t - t')(\nabla))}{(\nabla)} [2(X + Y) \otimes 1 + 2Y \otimes 1 - 2Y']
+ 2Z - 4\mathcal{J}^{(1)}(X + Y - Y' + 1)(t')dt' \right\|_{Y^{s_2}} \\
\lesssim \left\| (Y_0, Y_1) \otimes H^{s_2} + \left\| (X + Y - Y') \otimes 1 \right\|_{L^{1/2}_t H^{s_2-1}_x} + \left\| Y \otimes 1 \right\|_{L^{1/2}_t H^{s_2-1}_x} + \left\| Y' \right\|_{L^{1/2}_t H^{s_2-1}_x}
+ \left\| Z \right\|_{L^{1/2}_t H^{s_2-1}_x} + \left\| \mathcal{J}^{(1)}(X + Y - Y') \otimes 1 \right\|_{L^{1/2}_t H^{s_2-1}_x}
\lesssim \left\| (Y_0, Y_1) \otimes H^{s_2} + T(1 + \left\| X + Y - Y' \right\|_{L^\infty_t H^{s_2}_x} + \left\| Y \right\|_{L^\infty_t H^{s_2}_x})
\lesssim \left\| (Y_0, Y_1) \otimes H^{s_2} + T(1 + \left\| (X, Y) \right\|_{Z_t^{s_1, s_2}}),
$$

(6.3)

provided that $s_2 - 1 < \min(s_1 - \frac{1}{2} - 2\varepsilon, -\varepsilon)$ and $s_2 + (-\frac{1}{2} - \varepsilon) > 0$, namely,

$$
\frac{1}{2} < s_2 < \min(1, s_1 + \frac{1}{2}).
$$

Similarly, we have

$$
\left\| \int_0^t \frac{\sin((t - t')(\nabla))}{(\nabla)} \mathcal{J}_{\otimes, \otimes}(X + Y - Y)(t')dt' \right\|_{Y^{s_2}} \lesssim \left\| \mathcal{J}_{\otimes, \otimes}(X + Y - Y) \right\|_{L^{1/2}_t H^{s_2-1}_x}
\lesssim T \left\| X + Y - Y \right\|_{L^\infty_t L^{\infty}_{x} \cap C^{1/2}_t H^{1-\varepsilon}_x}
\lesssim T(1 + \left\| (X, Y) \right\|_{Z_t^{s_1, s_2}}),
$$

(6.4)

provided that $s_2 < 1$. Lastly, by Lemma 2.4 with the fractional Leibniz rule (Lemma 2.2), we have

$$
\left\| \int_0^t \frac{\sin((t - t')(\nabla))}{(\nabla)} (X + Y - Y)^2(t')dt' \right\|_{Y^{s_2}} \lesssim \left\| (\nabla)^{s_2 - \frac{1}{2}} (X + Y - Y)^2 \right\|_{L^{1/2}_t H^{1/2}_x}
\lesssim T \left( \left\| (\nabla)^{s_2 - \frac{1}{2}} X \right\|_{L^2_t L^2_x}^2 + \left\| (\nabla)^{s_2 - \frac{1}{2}} Y \right\|_{L^2_t L^2_x}^2 + \left\| (\nabla)^{s_2 - \frac{1}{2}} Y' \right\|_{L^2_x}^2 \right)
\lesssim T^\frac{1}{2} \left( 1 + \left\| (X, Y) \right\|_{Z_t^{s_1, s_2}}^2 \right),
$$

(6.5)

provided that $s_2 \leq \min(1 - \varepsilon, s_1 + \frac{1}{2})$.

From (6.2), (6.3), (6.4), and (6.5), we obtain

$$
\left\| \Phi(X, Y) \right\|_{Z_t^{s_1, s_2}} \lesssim \left\| (X_0, X_1) \right\|_{H^{s_1}} + \left\| (Y_0, Y_1) \right\|_{H^{s_2}} + T^\theta \left( 1 + \left\| (X, Y) \right\|_{Z_t^{s_1, s_2}} \right)
$$

(6.6)

for some $\theta > 0$. By repeating a similar computation, we also obtain the following estimate on the difference:

$$
\left\| \Phi(X, Y) - \Phi(\tilde{X}, \tilde{Y}) \right\|_{Z_t^{s_1, s_2}} \lesssim T^\theta \left( 1 + \left\| (X, Y) \right\|_{Z_t^{s_1, s_2}} + \left\| (\tilde{X}, \tilde{Y}) \right\|_{Z_t^{s_1, s_2}} \right) \left\| (X, Y) - (\tilde{X}, \tilde{Y}) \right\|_{Z_t^{s_1, s_2}}.
$$

(6.7)

Therefore, by choosing $T > 0$ sufficiently small (depending on the $\lambda^{s_1, s_2, \varepsilon}$-norm of the enhanced data set $\Xi$), we conclude from (6.6) and (6.7) that $\Phi$ in (1.39) is a contraction on the ball $B_R \subset Z_t^{s_1, s_2}$ of radius $R \sim \left\| (X_0, X_1) \right\|_{H^{s_1}} + \left\| (Y_0, Y_1) \right\|_{H^{s_2}}$. A similar computation yields continuous dependence of the solution $(X, Y)$ on the enhanced data set $\Xi$ measured in the $\lambda^{s_1, s_2, \varepsilon}$-norm. This concludes the proof of Theorem 1.12.
7. ON THE WEAK UNIVERSALITY OF THE RENORMALIZED SNLW

We conclude this paper by presenting the proof of Theorem 1.2. For the sake of concreteness, we take the Gaussian noise \( \eta_\kappa \) to be the mollified space-time white noise \( \rho \ast \xi \) on \( (\kappa^{-1} \mathbb{T})^3 \times \mathbb{R}_+ \) given by

\[
\eta_\kappa = \kappa^{\frac{3}{2}} \sum_{n \in \mathbb{Z}^3} \hat{\rho}(\kappa n) \frac{d\beta_n}{dt} e_{kn}, \tag{7.1}
\]

where \( \rho \) is a (smooth) mollification kernel with support in \( \mathbb{T}_3 \triangleq [-\frac{1}{2}, \frac{1}{2})^3 \), \( \{ \beta_n \}_{n \in \Lambda_0} \) is a family of mutually independent complex-valued Brownian motions and \( \beta_n := \beta_n, n \in \Lambda_0 \), as in (1.1). It is not difficult to see that \( \eta_\kappa \) is indeed a random field on \( (\kappa^{-1} \mathbb{T})^3 \times \mathbb{R}_+ \) which is smooth in space and white in time with stationary correlations.

Our aim is to describe the long time and large space behavior of the solution \( w_\kappa \) to (1.3). In order to do so, we perform a change of variables \( u_\kappa(x, t) = \kappa^{-2} w_\kappa(\kappa^{-1} x, \kappa^{-1} t) \) as in (1.4). Then, the equation (1.3) takes the form:

\[
\partial_t^2 u_\kappa + (1 - \Delta) u_\kappa = \kappa^{-4} f(\kappa^2 u_\kappa) + \kappa^{-4} a_\kappa^{(0)} + \kappa^{-2} a_\kappa^{(1)} u_\kappa + (1 - \kappa^{-2}) u_\kappa + \xi_\kappa \tag{7.2}
\]
on \( \mathbb{T}^3 \times \mathbb{R}_+ \). Here, \( \xi_\kappa(x, t) = \kappa^{-2} \eta_\kappa(\kappa^{-1} x, \kappa^{-1} t) \) is chosen so that \( \xi_\kappa \) converges in law to the space-time white noise \( \xi \) on \( \mathbb{T}^3 \times \mathbb{R}_+ \) as \( \kappa \to 0 \). Indeed, from (7.1), we deduce that

\[
\xi_\kappa = \sum_{n \in \mathbb{Z}^3} \hat{\rho}(\kappa n) \frac{d\beta_n}{dt} e_{kn}, \tag{7.3}
\]

where \( \{ \beta_n \}_{n \in \Lambda_0} \) is a family of mutually independent complex Brownian motions with the same joint law as \( \{ \beta_n \}_{n \in \Lambda_0} \) and \( \beta_n := \beta_n, n \in \Lambda_0 \). By taking

\[
\xi = \sum_{n \in \mathbb{Z}^3} \frac{d\beta_n}{dt} e_n
\]
as a realization of the space-time white noise \( \xi \), we see that \( \xi_\kappa \) converges to \( \xi \) in \( C^{\frac{3}{2} - \varepsilon}(\mathbb{R}_+; W^{\frac{3}{2} - \varepsilon, \infty}(\mathbb{T}^3)) \) (endowed with the compact-open topology) almost surely for any \( \varepsilon > 0 \).

By the Taylor remainder theorem, we can write the right-hand side of (7.2) (excluding \( \xi_\kappa \)) as

\[
\kappa^{-4} f(\kappa^2 u_\kappa) + \kappa^{-4} a_\kappa^{(0)} + \kappa^{-2} a_\kappa^{(1)} u_\kappa + (1 - \kappa^{-2}) u_\kappa
\]
\[
= \left\{ \kappa^{-4} f(0) + \kappa^{-4} a_\kappa^{(0)} \right\} + \left\{ \kappa^{-2} f'(0) + \kappa^{-2} a_\kappa^{(1)} + (1 - \kappa^{-2}) \right\} u_\kappa
\]
\[
+ \frac{f''(0)}{2} u_\kappa^2 + R_\kappa,
\]

where \( R_\kappa \) is the remainder given by

\[
R_\kappa = \kappa^2 u_\kappa^3 \int_0^1 \frac{f''(\tau \kappa^2 u_\kappa)}{6} (1 - \tau)^2 d\tau. \tag{7.4}
\]

Let \( t_\kappa \) be the solution of the linear equation:

\[
(\partial_t^2 + 1 - \Delta) t_\kappa = \xi_\kappa. \tag{7.5}
\]

Then, with \( b_\kappa(t) = \mathbb{E}\left[ (t_\kappa(t))^2 \right] \), we define the Wick power \( v_\kappa \) by

\[
v_\kappa = (t_\kappa)^2 - b_\kappa. \tag{7.6}
\]
We now choose the time-dependent parameters $a_\kappa^{(0)}$ and $a_\kappa^{(1)}$ by setting
\begin{equation}
    a_\kappa^{(0)} = -f(0) - \kappa^4 c_f b_\kappa \quad \text{and} \quad a_\kappa^{(1)} = -f'(0) + (1 - \kappa^2),
\end{equation}
where $c_f = \frac{f''(0)}{2}$. Then, by writing
\begin{equation}
    u_\kappa = 1_\kappa - w_\kappa,
\end{equation}
we see from (7.2), (7.4), and (7.7) that $v_\kappa$ satisfies
\begin{equation}
    \partial_t^2 w_\kappa + (1 - \Delta)w_\kappa = c_{f}v_\kappa + 2c_{f}1_\kappa w_\kappa + c_{f}w_\kappa^2 + R_\kappa,
\end{equation}
where we used (7.6) to replace $(1_\kappa)^2 - b_\kappa$ by $v_\kappa$. In the following, by scaling, we assume that $c_f = -1$.

Letting $Y_\kappa = (\partial_t^2 + 1 - \Delta)^{-1}(v_\kappa)$, we decompose $w_\kappa$ as
\begin{equation}
    w_\kappa = -Y_\kappa + X_\kappa + Y_\kappa
\end{equation}
as in Section 1. Then, by repeating the discussion in Section 1, we can rewrite the equation (7.8) for $w_\kappa$ into the following system for $X_\kappa$ and $Y_\kappa$:
\begin{align}
    X_\kappa(t) &= -2 \int_0^t \frac{\sin((t-t')(\nabla))}{(\nabla)} \left[ (X_\kappa + Y_\kappa - Y_\kappa) \odot 1_\kappa \right] (t') dt', \\
    Y_\kappa(t) &= - \int_0^t \frac{\sin((t-t')(\nabla))}{(\nabla)} \left[ (X_\kappa + Y_\kappa - Y_\kappa)^2 + 2(X_\kappa + Y_\kappa - Y_\kappa) \odot 1_\kappa \right. \\
    &\quad \quad + 2Y_\kappa \odot 1_\kappa - 2Y_\kappa - R_\kappa \\
    &\quad \quad \left. - 4\partial_{\odot}^2 (X_\kappa + Y_\kappa - Y_\kappa) \odot 1 - 4\partial_{\odot}^2 (X_\kappa Y_\kappa - Y_\kappa) \right] (t') dt',
\end{align}
where $\gamma_{\kappa} = Y_\kappa \odot 1$ and $\gamma_{\odot,\odot}^\kappa$ is defined as in (1.30) with $1$ replaced by $1_\kappa$.

Let $\frac{1}{3} < s_1 < \frac{1}{3} < s_2 \leq s_1 + \frac{1}{3}$. Note that the rescaled noise $\xi_\kappa$ in (7.3) is basically the mollified space-time white noise. Hence, it is easy to see that the enhanced data set associated with the rescaled noise $\xi_\kappa$:
\begin{equation}
    \Xi_\kappa = (0, 0, 0, 0, 1_\kappa, Y_\kappa, \gamma_{\kappa}, 0, \gamma_{\odot,\odot}^\kappa)
\end{equation}
belongs to the class $\mathcal{X}^{s_1,s_2,\varepsilon}_t$ defined in (1.38) since $1_\kappa, Y_\kappa, \gamma_{\kappa}$, and $\gamma_{\odot,\odot}^\kappa$ satisfy the statement analogous to Lemma 3.1 and Propositions 1.6, 1.8, and 1.11.

Note that the system (7.9) is analogous to the original system (1.39) with the enhanced data set $\Xi$ replaced by $\Xi_\kappa$ and an additional source term given by the remainder term $R_\kappa$. In the following, we proceed as in the proof of Theorem 1.12 and prove local well-posedness of the system (7.9) for $\kappa > 0$ on a time interval $[0, T]$, where $T = T(\omega)$ is an almost surely positive stopping time, independent of $\kappa > 0$. Under the assumption $\|f''\|_{L^\infty} < \infty$, we have $R_\kappa = O(\kappa^2 u_\kappa^3)$, where
\begin{equation}
    u_\kappa = 1_\kappa - Y_\kappa + X_\kappa + Y_\kappa.
\end{equation}
In order to handle the cubic structure of $R_\kappa$, we need to modify the norm for the second component $Y_\kappa$. Let $s_2 = \frac{1}{2} + \sigma$ with some small $\sigma > 0$. Noting that $(\frac{4}{1+2\sigma}, \frac{4}{1-2\sigma})$ is $s_2$-admissible, we define the $\tilde{Y}^{s_2}_T$-space by the norm:
\begin{equation}
    \tilde{Y}^{s_2}_T = C([0, T]; H^{s_2}(T^3)) \cap C^1([0, T]; H^{s_2-1}(T^3)) \cap L^{\frac{4}{1+2\sigma}}([0, T]; L^{\frac{4}{1-2\sigma}}(T^3))
\end{equation}
and set
\[ \tilde{Z}_T^{s_1,s_2} = X_T^{s_1} \times \tilde{Y}_T^{s_2}, \]
where \( X_T^{s_1} \) is as in (6.1). In the following, we use the fact that \( (4/3,4/3) \) is dual \( s_2 \)-admissible.

Note that (6.2), (6.3), and (6.4) hold true even after replacing \( Z_T^{s_1,s_2} \) and \( Y_T^{s_2} \) by \( \tilde{Z}_T^{s_1,s_2} \) and \( \tilde{Y}_T^{s_2} \), respectively. Instead of (6.5), from the Strichartz estimates (Lemma 2.4) and Sobolev’s inequality on \( X \), we have
\[
\left\| \int_0^t \sin((t-t')\langle \nabla \rangle) \left( X_\kappa + Y_\kappa - Y_\kappa \right)^2(t') dt' \right\|_{Y_T^{s_2}} \lesssim \| X_\kappa + Y_\kappa - Y_\kappa \|_{L_T^{4/3} L_x^{4/3}}^2 \lesssim T^\theta \left( \| X_\kappa \|_{L_T^{s_1} L_x^{s_1}}^2 + \| Y_\kappa \|_{L_T^{s_1} L_x^{s_1}}^2 + \| Y_\kappa \|_{L_T^{s_1} L_x^{s_1}}^2 \right) \]
\[
\lesssim C(\omega) T^\theta \left( 1 + \| (X_\kappa, Y_\kappa) \|_{Z_T^{s_1,s_2}}^2 \right) \quad (7.11)
\]
for some \( \theta > 0 \), provided that \( s_1 - 1/4 \geq 3\sigma/2 \), which allows us to apply Sobolev’s inequality:
\[ \| X_\kappa \|_{L_T^{s_1} L_x^{s_1}} \lesssim \| X_\kappa \|_{L_T^{s_1} W_x^{s_1 - 1/4}} \]. Given \( s_1 > 1/4 \), this condition can be satisfied by choosing \( \sigma > 0 \) sufficiently small.

Next, we estimate the contribution from the remainder term \( R_\kappa \). From (7.3) and (7.5), we see that \( \tilde{\kappa}(n,t) \) is essentially supported on the spatial frequencies \( \{ |n| \leq \kappa^{-1} \} \). Hence, we have \( \kappa^{1+\epsilon} \kappa \in L^\infty([0,T];L^\infty (\mathbb{T}^3)) \) almost surely for any \( \epsilon > 0 \). By a similar reasoning, the paracontrolled structure of the \( X_\kappa \)-equation in (7.9) allows us to conclude that \( X_\kappa \) essentially has the spatial frequency support on \( \{ |n| \leq \kappa^{-1} \} \). Therefore, from Lemma 2.4 (7.4) with \( \| f'' \|_{L^\infty} < \infty \), and Sobolev’s inequality, we have
\[
\left\| \int_0^t \sin((t-t')\langle \nabla \rangle) R_\kappa(t') dt' \right\|_{Y_T^{s_2}} \lesssim \kappa^2 \| (1 - Y_\kappa + X_\kappa + Y_\kappa)^3 \|_{L_T^{4/3} L_x^{4/3}} \lesssim \kappa^{2-3\epsilon} T \left( \| 1 \|_{L_T^{s_1} L_x^{s_1}} + \| Y_\kappa \|_{L_T^{s_1} L_x^{s_1}}^3 \right) \]
\[
\lesssim \kappa^{3/2 - 3\epsilon} T \left( \| 1 \|_{L_T^{s_1} L_x^{s_1}} + \| Y_\kappa \|_{L_T^{s_1} L_x^{s_1}}^3 \right) \quad (7.12)
\]
for some \( \delta, \theta > 0 \). Here we used the frequency support of \( X_\kappa \) and Sobolev’s inequality to bound
\[ \| \kappa^{3/2 - \delta} X_\kappa \|_{L_T^{s_1} L_x^{s_1}} \lesssim \| X_\kappa \|_{L_T^{s_1} W_x^{s_1 - 1/4}} \lesssim \| X_\kappa \|_{L_T^{s_1} W_x^{s_1 - 1/4}} \]
which holds when \( 3(3/2 - 3\epsilon/2) / 12 = 3 \sigma + \sigma \leq (s_1 - 1/4) + (3/2 - \delta) = s_1 + 1/2 - \delta \). This last condition is guaranteed by choosing \( \sigma, \delta > 0 \) sufficiently small. Note that we used the following bound:
\[ \| Y_\kappa \|_{L_T^{s_1} L_x^{s_1}} \lesssim \| Y_\kappa \|_{L_T^{s_1} L_x^{s_1}} \]
Lastly, we point out that it was important to use \( s_2 \)-admissible and dual \( s_2 \)-admissible pairs such that there is no derivative on \( R_\kappa \) after applying the Strichartz estimate in (7.12). Otherwise, a (fractional) derivative would fall on \( f''(\tau \kappa^2 u_\kappa) \) in (7.4) and we would need to use the fractional chain rule, which would make the computation far more complicated.

Putting (6.2), (6.3), (6.4), (7.11), and (7.12) together, we conclude that the system (7.9) is locally well-posed on \([0,T]\), where \( T = T(\omega) \) is an almost surely positive stopping time, independent of \( \kappa > 0 \).
As for the sequence $\{\Xi_N\}_{N \in \mathbb{N}}$ above, one can show that, at least along subsequences, the family $\{\Xi_\kappa\}_{\kappa \in (0,1)}$ in (7.10) converges (in the natural $A^1_{\alpha,\beta,\varepsilon}$-topology) almost surely towards the random vector $\Xi$ given by (1.41) with $(u_0, u_1) = (0, 0)$. Let $(X, Y)$ be the solution to the original system (1.39) with this random data $\Xi$ and set $u$ by (1.42). Then, by using the above estimates, we can estimate the difference $(X - X_\kappa, Y - Y_\kappa)$. As a consequence, we conclude that that, along any countable sequence, $u_\kappa$ converges to the same limit $u$ in $C([0,T]; H^{-\frac{1}{2}-\varepsilon}(\mathbb{T}^3))$ almost surely (and hence in probability), where $T = T(\omega)$ is a random local existence time whose size depends only on the random data $\Xi$, in particular, independent of $\kappa \to 0$. Since the limit $u$ does not depend on a particular countable sequence of $\kappa \to 0$, we can deduce that the whole family $\{u_\kappa\}_{\kappa \in (0,1)}$ converges in probability towards $u$. This completes the proof of Theorem 1.2.
