(Dated: September 15, 2014)

We derive the most general evolution equations describing in-medium neutrino propagation in the mean-field approximation. In particular, we consider various types of neutrino-antineutrino mixing, both for Dirac and for Majorana fields, resulting either from nontrivial pair correlations or from helicity coherence due to the nonvanishing neutrino masses. We show that for inhomogeneous or anisotropic systems, these correlations are sourced by the usual neutrino and antineutrino densities. This may be of importance in astrophysical environments such as core-collapse supernovae.

I. INTRODUCTION

Neutrinos are connected with key open questions on fundamental interactions and astrophysical observations. Unknown are the neutrino mass and mass ordering, the neutrino nature, the existence of sterile neutrinos or leptonic CP violation. It is also to be established how much and how neutrinoses influence the gravitational explosion of massive stars and the outcomes of stellar nucleosynthesis processes such as the r-process. Identifying the answers to the latter requires the detailed investigation of numerous astrophysical aspects, including an in-depth understanding and accurate treatment of the neutrino flavour evolution in dense environments.

A steady progress has been made since the assessment of the Mikheev-Smirnov-Wolfenstein (MSW) effect as a solution of the high energy solar neutrino deficit problem\cite{1,2}. The neutrino self-interaction and dynamical aspects, such as turbulence and the presence of shock-waves, have been shown to induce neutrino flavour change in the case of massive stars undergoing gravitational core-collapse (see e.g.\cite{4}).

It was long speculated that neutrino flavour change in matter could impact the supernova dynamics. While the MSW effect occurs in the supernova outer layers, the neutrino-neutrino interaction introduces a non-linear refraction index\cite{5} that produces flavour change in deep regions nearby the neutrinosphere. Assessing the impact of neutrino self-interactions requires further investigations since their effects might be diluted, or even suppressed due to decoherence effects in realistic simulations (see e.g.\cite{6,7} for reviews and\cite{8}). Quantitative evaluations of the neutrino flavour change impact on shock-waves seem to indicate that the conversion occurs outside the gain region and does not affect the explosion\cite{9}. Moreover, the neutrino self-interaction might impact the heavy elements abundances in neutrino-driven winds in supernovae\cite{10,11}, or in accretion-disks in neutron star- (or black hole)-neutron star mergers\cite{12}. These studies and the predictions for supernova neutrino signals are usually made by assuming that the interaction of neutrinos within the star can be accounted for by an effective Hamiltonian and evolution equations valid in the mean-field approximation. On the other hand, the neutrino transport within the neutrinosphere is based on a Boltzmann treatment for particles without mixings\cite{13}. Exploring the validity of the mean-field approximation is among the necessary steps to put investigations of neutrino flavour conversion and their impact on a solid ground. This requires to study the role of two body correlations from the high density region, where neutrinos are trapped, to the low density regime, where they start free-streaming.

Equations describing in-medium neutrino propagation have been derived using various approaches either at the mean-field level\cite{14,17}, or including collisions\cite{18,21}. In the context of supernova physics, various evolution equations beyond the mean-field approximation have been obtained using different theoretical frameworks. Ref.\cite{16} shows that the neutrino mean-field equations, including the neutrino–matter and neutrino–neutrino interactions, correspond to a saddle point approximation for the coherent state path integral representation of the evolution operator. Implicit corrections beyond the saddle point approximation are also given. Refs.\cite{22,23} use an al-
gebraic approach to show that the full many-body problem associated with the neutrino self-interaction Hamiltonian (without the matter term) is exactly solvable. This Hamiltonian is related to the (reduced) one describing Bardeen-Cooper-Schrieffer (BCS) superconductivity \[22\]. In Ref. \[24\], re-scattered neutrinos are considered in a schematic way to mimic few collisions outside the neutrinosphere, showing that a small fraction of back-scattered particles can produce modified flavour patterns. Collisions are formally consistently included in \[21\] where the two-particle-irreducible (2PI) effective action formalism \[22\] is employed to derive evolution equations for the two-point correlation function.

A different class of corrections to the standard mean-field equations arises from considering various nontrivial two-point correlations beyond the usual neutrino and antineutrino density matrices in flavor space. Specific particle-antiparticle correlations for Majorana neutrinos, corresponding to quantum-mechanical coherence between states of opposite helicities can be present, e.g., due to the coupling of a nonzero neutrino magnetic moment to intense magnetic fields in supernovae or from the neutrino masses. Numerical results show that the former can modify the neutrino fluxes and produce neutrino-antineutrino conversion, even for a Standard Model magnetic moment \[26\]. These correlations also naturally arise in nonpolarized media when contributions from the nonzero neutrino masses are taken into account, as observed in \[21, 27\], where generalized kinetic equations implementing helicity coherence have been derived.

Contributions to the mean-field Hamiltonian proportional to powers of the neutrino masses have been first discussed in Ref. \[17\], where the possible relevance of two-point correlators arising from neutrino-antineutrino pairing correlations has been pointed out. These have been included in extended mean-field equations using first principle quantum field theoretical techniques based on systematic truncations of the Born-Bogoliubov-Green-Kirkwood-Yvon (BBGKY) hierarchy \[1, 29\]. Contributions from the neutrino mass to abnormal neutrino-antineutrino correlators are also discussed. The linearized version of these extended equations has been derived in \[31\] using methods from the theory of atomic nuclei and metallic clusters, establishing a link between the collective stable and unstable modes of these many-body systems and those of a gas of self-interacting neutrinos in a dense medium.

Similar two-body pairing correlations play a nontrivial role in various areas of physics, from atomic nuclei to condensed matter and astrophysical systems such as neutron stars. In strongly interacting systems, e.g., atomic nuclei, pairing between equal-like particles (protons or neutrons) and unlike particles (neutrons and protons) are of key importance in correctly determining the properties of the ground state and of the excited states and in describing nuclear dynamics. In the original BCS theory, the long-range electron-phonon attractive interaction produces electron Cooper pairs responsible for superconductivity \[51\]. In relativistic theories, the possible relevance of particle-antiparticle pairing correlations have been pointed out in the context of lepto/baryogenesis in \[32, 33\].

In the present work, we derive the most general mean-field equations for Dirac and Majorana neutrinos including all possible types of two-point correlators. The corresponding evolution equations involve nontrivial particle-antiparticle mixing terms. We first give expressions valid for a general inhomogeneous system of self-interacting massive neutrinos. We then specify our equations to the case of a spatially homogeneous system and we discuss separately pairing correlations and helicity coherence terms. We treat the former in the limit of ultrarelativistic neutrinos. For the latter, we include nonrelativistic corrections since they arise from the nonvanishing neutrino masses. We discuss the conditions for nonvanishing neutrino-antineutrino mixing contributions. In particular, this typically requires spatial anisotropies of the matter and/or neutrino backgrounds, although we identify some contributions which are present even for isotropic systems. We derive the mean field Hamiltonian for a typical astrophysical environment made of electrons, nucleons and (anti)neutrinos. In general the latter depend both on the neutrino and the antineutrino densities and on the various neutrino-antineutrino correlations. We compare our findings with the previous results of Refs. \[17, 21, 27\].

The paper is structured as follows. Our procedure and general mean-field equations for massive neutrinos in an inhomogeneous background are given for Dirac and Majorana fields in Section II. In Section III we focus on the role of pair correlations, specializing to spatially homogeneous systems with ultrarelativistic neutrinos; while helicity coherence is investigated in Section IV. We conclude in Section V. General equations combining pairing correlations and helicity coherence are presented in Ap-
II. GENERAL MEAN-FIELD EQUATIONS

At any time, the (quantum) state of the system of interest – here the neutrino gas – can be fully characterized by the values of equal-time correlators of field operators. In general, the latter obey an infinite set of coupled evolution equations, the quantum field theory generalization of the BBGKY hierarchy \[13, 29\]. Alternatively, these can be obtained from unequal-time correlators, which also satisfy an infinite set of coupled integro-differential equations known as the Kadanoff-Baym equations \[34\]. In any case, lower order correlators depend on higher order ones and one needs to close the hierarchy in one way or another. Powerful systematic approximation schemes can be based on 2PI functional techniques, where \(n\)-point correlation functions are expressed in terms of the full propagator, to be determined self-consistently \[35\]. In particular, this provides a convenient starting point to derive kinetic (e.g. Boltzmann) equations when a gradient expansion is justified \[21, 36\].

The mean-field, or Hartree-Fock approximation is the simplest nontrivial closure of such hierarchies. Physically, it corresponds to the propagation of the (anti)particles of interest in the averaged background field generated by the particles of the medium (possibly including self-interactions). Technically, it amounts to replacing all \(n\)-point correlators by their Gaussian expression in terms of the two-point function. In the 2PI formalism this is typically obtained as the lowest non-trivial order of a loop expansion of the 2PI effective action. This neglects dissipation due to direct collisions and memory effects \[35\] and can be described by an effective bilinear Hamiltonian.

Here, we consider the evolution equations for the equal-time two-point correlators of the (anti)neutrino system corresponding to a general bilinear Hamiltonian, to be specified later. We discuss separately the cases of Dirac and Majorana neutrino fields.

A. Dirac neutrinos

We wish to obtain the evolution equations for the neutrino two-point correlators in the case where the effective Hamiltonian takes the general bilinear form (we use \(h = c = 1\) units)

\[
H_{\text{eff}}(t) = \int d^3x \, \bar{\psi}_i(t, \vec{x}) \Gamma_{ij}(t, \vec{x}) \psi_j(t, \vec{x}),
\]

where \(\psi_i\) denotes the \(i\)-th component of the neutrino field in the mass basis \(\psi_i \equiv U_{ai} \phi_i\). The explicit expression of the kernel \(\Gamma\) is not needed here and will be specified later. At each time the spatial Fourier decomposition of a Dirac neutrino field reads

\[
\psi_i(t, \vec{x}) = \int_{\vec{p},s} e^{i\vec{p} \cdot \vec{x}} \psi_i(t, \vec{p}, s)
\]

with

\[
\psi_i(t, \vec{p}, s) = a_i(t, \vec{p}, s) u_i(\vec{p}, s) + b_i(t, -\vec{p}, s) v_i(-\vec{p}, s),
\]

where we note \(\int_{\vec{p}} \equiv \int \frac{d^3p}{(2\pi)^3}\) and \(\int_{\vec{p},s} \equiv \int_{\vec{p}} \sum_s\). Here, \(a_i(t, \vec{p}, s)\) and \(b_i(t, \vec{p}, s)\) are the standard particle and antiparticle annihilation operators (in the Heisenberg picture) for (anti)neutrinos of mass \(m_i\), momentum \(\vec{p}\) and helicity \(s\). The nonzero equal-time anticommutation relations read

\[
\{a_i(t, \vec{p}, s), a_j^\dagger(t, \vec{p}', s')\} = (2\pi)^3 \delta^{(3)}(\vec{p} - \vec{p}') \delta_{ss'} \delta_{ij}
\]

and similarly for the anti-particle operators. The Dirac spinors corresponding to mass eigenstates \(i\) are normalized as (no sum over \(i\))

\[
u_i^\dagger(\vec{p}, s) u_i(\vec{p}, s') = v_i^\dagger(\vec{p}, s) v_i(\vec{p}, s') = \delta_{ss'}.
\]

In the flavor basis, the field operator (possibly including sterile neutrinos) is obtained as

\[
\psi_\alpha(t, \vec{x}) = U_{\alpha i} \psi_i(t, \vec{x}),
\]

with \(U\) the Maki-Nakagawa-Sakata-Pontecorvo unitary matrix \(\mathbf{U}\). In the three-flavor framework, the corresponding neutrino mixing angles are precisely measured, while the Dirac and two-Majorana CP violating phases are still unknown \[37\].

---

\[1\] We work here in the mass eigenstate basis, or propagation basis in vacuum. Alternatively one can write equivalent expressions using the matter basis, which is the basis that instantaneously diagonalizes the total neutrino Hamiltonian (including the neutrino-matter interaction and the self-interaction). Note that in the flavour basis the (anti)neutrino creation and annihila-

---

\[2\] tion operators do not satisfy the usual anticommutation relations, unless neutrinos are relativistic \[35\].
In the case of Dirac neutrinos, we neglect possible lepton-number violating correlators. The set of equal-time two-point correlators is fully characterized by

\[ \rho_{ij}(t, \vec{q}, h, \vec{q}', h') = \langle a^\dagger_i(t, \vec{q}', h') a_i(t, \vec{q}, h) \rangle \]  

(7)

\[ \bar{\rho}_{ij}(t, \vec{q}, h, \vec{q}', h') = \langle b^\dagger_j(t, \vec{q}, h) b_j(t, \vec{q}', h') \rangle \]  

(8)

\[ \kappa_{ij}(t, \vec{q}, h, \vec{q}', h') = \langle b_j(t, \vec{q}', h') a_i(t, \vec{q}, h) \rangle \]  

(9)

\[ \kappa^\dagger_{ij}(t, \vec{q}, h, \vec{q}', h') = \langle a^\dagger_j(t, \vec{q}', h') b^\dagger_i(t, \vec{q}, h) \rangle \]  

(10)

where the brackets denote quantum and statistical average over the medium through which neutrino are propagating. Here, \( \rho \) and \( \bar{\rho} \) describe generalized particle and antiparticle number densities whereas \( \kappa \) and \( \kappa^\dagger \) correspond to particle-antiparticle pair correlations. Note that the particle and antiparticle correlators, \( \rho \) and \( \bar{\rho} \), include normal densities with all possible helicity states, including the “wrong” ones, e.g., \( \rho_{ij}(t, \vec{q},+,\vec{q}',+) \) or \( \bar{\rho}_{ij}(t, \vec{q},-,\vec{q}',-) \) as well as possible coherence terms such as \( \rho_{ij}(t, \vec{q},-,\vec{q}',+) \). Our notation is such that the Hermitian conjugation in (10) involves both mass indices and space-time variables, i.e.,

\[ \kappa_{ij}(\vec{q}, h, \vec{q}', h') = \kappa^*_{ji}(\vec{q}', h', \vec{q}, h) \]  

(11)

Let us derive the general evolution equations for the two-point correlators (7)-(10). To ease the derivation and the presentation, it is useful to introduce some notations. We first define the spinor products

\[ \Gamma^{\rho^\dagger}(t, \vec{q}, h, \vec{q}', h') = \bar{u}_i(\vec{q}, h) \bar{\Gamma}_{ij}(t, \vec{q} - \vec{q}', h') \]  

(12)

\[ \Gamma^{\bar{\rho}}(t, \vec{q}, h, \vec{q}', h') = \bar{v}_i(\vec{q}, h) \bar{\Gamma}_{ij}(t, -\vec{q} + \vec{q}', h') \]  

(13)

and

\[ \Gamma^{\rho^\dagger}_i(t, \vec{q}, h, \vec{q}', h') = \bar{u}_i(\vec{q}, h) \bar{\Gamma}_{ij}(t, \vec{q} + \vec{q}', h') \]  

(14)

\[ \Gamma^{\bar{\rho}}_i(t, \vec{q}, h, \vec{q}', h') = \bar{v}_i(\vec{q}, h) \bar{\Gamma}_{ij}(t, -\vec{q} - \vec{q}', h') \]  

(15)

with the Fourier transform of the mean-field defined as

\[ \bar{\Gamma}_{ij}(t, \vec{p}) = \int d^3 \vec{x} e^{i\vec{p} \cdot \vec{x}} \bar{\Gamma}_{ij}(t, \vec{x}). \]  

(16)

We use a matrix notation in both mass indices and space-time variables in which, for instance, \( \Gamma^{\rho^\dagger}_{ij}(t, \vec{q}, h, \vec{q}', h') \) is the matrix element of \( \Gamma^{\rho^\dagger}(t) \). The matrix product involves both a sum over the discrete (mass/energy and helicity) indices and an integral over the continuous (momentum) variables, i.e.,

\[ [A \cdot B]_{ij}(\vec{q}, h, \vec{q}', h') \equiv \int d^3 \vec{p}s A_{ik}(\vec{q}, h, \vec{p}, s) B_{kj}(\vec{p}, s, \vec{q}'', h'). \]  

(18)

In this notation, the operators \( a(t) \) and \( b(t) \) are to be seen as column vectors and \( \rho(t), \bar{\rho}(t) \) and \( \kappa(t) \) in Eqs. (7)-(10) as well as the \( \Gamma(t) \)'s in Eqs. (12)-(15) as matrices. The effective Hamiltonian (11) takes the compact form

\[ H_{\text{eff}}(t) = a^\dagger(t) \cdot \Gamma^{\rho^\dagger}(t) \cdot a(t) + b(t) \cdot \Gamma^{\bar{\rho}}(t) \cdot b^\dagger(t) + a^\dagger(t) \cdot \Gamma^{\rho^\dagger}(t) \cdot b(t) + b(t) \cdot \Gamma^{\bar{\rho}}(t) \cdot a(t). \]  

(19)

and the equal-time anticommutation relations (21) read

\[ \{a(t), a^\dagger(t)\} = 1. \]  

(20)

The hermiticity of the effective Hamiltonian implies

\[ [\Gamma^{\rho^\dagger}(t)]^\dagger = \Gamma^{\rho^\dagger}(t) \]  

(21)

\[ [\Gamma^{\bar{\rho}}(t)]^\dagger = \Gamma^{\bar{\rho}}(t) \]  

(22)

\[ [\Gamma^{\rho^\dagger}(t)]^\dagger = \Gamma^{\rho^\dagger}(t). \]  

(23)

The evolution equations for the correlator (7) can be obtained as

\[ i\hbar \dot{\rho}_{ij}(t, \vec{q}, h, \vec{q}', h') = \{a^\dagger_j(t, \vec{q}', h') a_i(t, \vec{q}, h), H_{\text{eff}}(t)\}. \]  

(24)

Using Eq. (17) and the anticommutation relations (14), one easily expresses the right-hand side in terms of the
two-point correlators [9]-[10]:

\[ i\dot{\rho}_{ij}(t,\vec{q},h,\vec{q}',h') = \int_{\vec{p},s} \left[ \Gamma^{\nu
u}_{ik}(t,\vec{q},h,\vec{p},s) \rho_{kj}(t,\vec{p},s,\vec{q}',h') \\
- \rho_{ik}(t,\vec{q},h,\vec{p},s) \Gamma^{\nu
u}_{kj}(t,\vec{p},s,\vec{q}',h') \\
+ \Gamma^{\nu\bar{\nu}}_{ik}(t,\vec{q},h,\vec{p},s) \kappa^j_{kj}(t,\vec{p},s,\vec{q}',h') \\
- \kappa_{ik}(t,\vec{q},h,\vec{p},s) \Gamma^{\nu\bar{\nu}}_{kj}(t,\vec{p},s,\vec{q}',h') \right]. \tag{25} \]

Using the matrix notation introduced above, this takes the compact form

\[ i\dot{\rho}(t) = \Gamma^{\nu
u}(t) \cdot \rho(t) - \rho(t) \cdot \Gamma^{\nu
u}(t) \\
+ \Gamma^{\nu\bar{\nu}}(t) \cdot \kappa(t) - \kappa(t) \cdot \Gamma^{\nu\bar{\nu}}(t), \tag{26} \]

The evolution equation for the antineutrino density is obtained along the same lines as

\[ i\dot{\bar{\rho}}(t) = \Gamma^{\bar{\nu}\bar{\nu}}(t) \cdot \bar{\rho}(t) - \bar{\rho}(t) \cdot \Gamma^{\bar{\nu}\bar{\nu}}(t) \\
- \Gamma^{\nu\bar{\nu}}(t) \cdot \kappa(t) + \kappa(t) \cdot \Gamma^{\nu\bar{\nu}}(t), \tag{27} \]

Finally, the evolution equation for the neutrino-antineutrino pairing correlator reads

\[ i\dot{\kappa}(t) = \Gamma^{\nu\bar{\nu}}(t) \cdot \kappa(t) - \kappa(t) \cdot \Gamma^{\nu\bar{\nu}}(t) \\
- \Gamma^{\nu\bar{\nu}}(t) \cdot \bar{\rho}(t) - \bar{\rho}(t) \cdot \Gamma^{\nu\bar{\nu}}(t) \\
+ \Gamma^{\nu\bar{\nu}}(t) \tag{28} \]

and similarly for \(\kappa(t)\).

We mention that these general evolution equations can be gathered together by introducing a further level of matrix notation. Following [17], we define

\[ \mathcal{H}(t) = \begin{pmatrix} \Gamma^{\nu
u}(t) & \Gamma^{\nu\bar{\nu}}(t) \\ \Gamma^{\bar{\nu}\nu}(t) & \Gamma^{\bar{\nu}\bar{\nu}}(t) \end{pmatrix}, \tag{29} \]

and

\[ \mathcal{R}(t) = \begin{pmatrix} \rho(t) & \kappa(t) \\ \kappa(t)^\dagger \mathbb{1} - \bar{\rho}(t) \end{pmatrix}, \tag{30} \]

in terms of which Eqs. (26)-(28) rewrite

\[ i\dot{\mathcal{R}}(t) = [\mathcal{H}(t),\mathcal{R}(t)]. \tag{31} \]

Note that the conservation of the total lepton number, defined as

\[ L = \text{tr} [\rho(t) - \bar{\rho}(t)] = \int_{\vec{p},s} \left[ \rho_{ii}(t,\vec{p},\vec{p},s) - \bar{\rho}_{ii}(t,\vec{p},\vec{p},s) \right], \tag{32} \]

follows immediately from \(\text{tr} \dot{\mathcal{R}}(t) = 0\).

We emphasize that the evolution equations (26)-(28) include all possible correlators between the various helicity states of both particles and antiparticles and encompass all mean-field evolution equations discussed so far in the literature for Dirac neutrinos. Let us now discuss the case of Majorana neutrinos.

\section{Majorana neutrinos}

The general mean-field Hamiltonian for Majorana fields reads:\footnote{We use the same notation as in the Dirac case for the kernel \(\Gamma\) for simplicity although one should keep in mind that the respective vacuum (free) contributions differ by a factor \(1/2\) to cope for the different number of degrees of freedom [36].}

\[ H_{\text{eff}}^M(t) = \int d^3x \bar{\psi}_i^M(t,\vec{x})\Gamma_{ij}(t,\vec{x})\psi_j^M(t,\vec{x}), \tag{33} \]

where

\[ \psi_i^M(t,\vec{x}) = \int_{\vec{p},s} e^{i\vec{p}\cdot\vec{x}} \psi_i^M(t,\vec{p},s), \tag{34} \]

with

\[ \psi_i^M(t,\vec{p},s) = a_i(t,\vec{p},s)u_i(\vec{p},s) + a_i^\dagger(t,-\vec{p},s)v_i(-\vec{p},s). \tag{35} \]

The evolution equations for Majorana fields can be formally obtained from those derived in the previous section by replacing the antiparticle operators by particle ones: \(b \rightarrow a\). Using the notation introduced above, Eq. (33) can be written in the symmetric form

\[ H_{\text{eff}}^M(t) = \frac{1}{2} \left[ a_i^\dagger(t) \cdot \Gamma_{ii}^{\nu\nu}(t) \cdot a(t) + a(t) \cdot \Gamma_{ii}^{\nu\bar{\nu}}(t) \cdot a_i^\dagger(t) \\
+ a_i^\dagger(t) \cdot \Gamma_{ij}^{\nu\bar{\nu}}(t) \cdot a_j^\dagger(t) + a(t) \cdot \Gamma_{ij}^{\nu\nu}(t) \cdot a_j(t) \right], \tag{36} \]

where we defined

\[ \Gamma_{ii}^{\nu\nu}(t) = \Gamma^{\nu\nu}(t) - [\Gamma^{\bar{\nu}\bar{\nu}}(t)]^T \tag{37} \]

\[ \Gamma_{ii}^{\nu\bar{\nu}}(t) = \Gamma^{\nu\bar{\nu}}(t) - [\Gamma^{\nu\bar{\nu}}(t)]^T \tag{38} \]

\[ \Gamma_{ij}^{\nu\nu}(t) = \Gamma^{\nu\nu}(t) - [\Gamma^{\nu\bar{\nu}}(t)]^T \tag{39} \]

\[ \Gamma_{ij}^{\nu\bar{\nu}}(t) = \Gamma^{\nu\bar{\nu}}(t) - [\Gamma^{\nu\nu}(t)]^T. \tag{40} \]
Note the relations
\[ (\Gamma^\mu_M(t))^T = -\Gamma^\mu_M(t) \]  
\[ (\Gamma^\mu_M(t)) = -\Gamma^\mu_M(t) \]  
\[ (\Gamma^\mu_M(t)) = -\Gamma^\mu_M(t), \]  
where the superscript T stands for transposition in both mass indices and space-time variables.

The most general set of equal-time two-point correlators include generalized particle densities \( \rho_M = \langle a^\dagger a \rangle \) and pair correlations \( \kappa_M = \langle aa \rangle \). We define the latter as in (7)-(10), with the obvious relations
\[ \bar{\rho}_M(t) = \left( \rho_M(t) \right)^T \]  
\[ \kappa_M(t) = -\left[ \kappa_M(t) \right]^T. \]  

Although Majorana particles are their own antiparticles, it is the usual practice to refer to negative and positive helicity states as “particles” and “antiparticles”. As in the Dirac case, the particle and pair correlators \( \rho_M \) and \( \kappa_M \) include all possible helicity states. In particular, both the usual “particle” and “antiparticle” densities are encoded in \( \rho_M \), as \( \rho_M^i(t, \vec{q}, -\vec{q}', -j) \) (or \( \rho_M^i(t, \vec{q}, +\vec{q}', +j) \)). Equivalently, the latter is given by \( \bar{\rho}_M^i(t, \vec{q}', +\vec{q}, j) \) (or \( \bar{\rho}_M^i(t, \vec{q}', -\vec{q}, j) \)), using (14). The other, nondiagonal helicity components of \( \rho_M \) describe “particle-antiparticle” coherence of the type discussed in 21, 26.

The pair correlations encoded in \( \kappa_M \) describe other kind of coherences either of the type “particle-antiparticle”, with \( \kappa_M^i(t, \vec{q}, +\vec{q}', -j) \), or “particle-particle” and “antiparticle-antiparticle”, with \( \kappa_M^i(t, \vec{q}, -\vec{q}', +j) \) and \( \kappa_M^i(t, \vec{q}, +\vec{q}', +j) \) respectively, as first discussed in 17. Note that, in contrast to the Dirac case, the Majorana pair correlations \( \kappa_M \) violate the total lepton number 3.

The general mean-field equations 29 and 28 derived in the previous section for Dirac fields keep the very same form for Majorana fields with the replacements \( \Gamma \rightarrow \Gamma_M \), \( \rho \rightarrow \rho_M \), and \( \kappa \rightarrow \kappa_M \). Specifically, introducing
\[ H_M(t) = \begin{pmatrix} \Gamma^\mu_M(t) & \Gamma^\mu_M(t) \\ \Gamma^\mu_M(t) & -[\Gamma^\mu_M(t)]^T \end{pmatrix} \]  
and
\[ R_M(t) = \begin{pmatrix} \rho_M(t) & \kappa_M(t) \\ \kappa_M(t) & 1 - \rho_M(t) \end{pmatrix}, \]  
one has
\[ i\dot{R}_M(t) = [H_M(t), R_M(t)]. \]  

One easily checks that the Dirac evolution equations in the Dirac case reduce to those in the Majorana case when the symmetry properties 11, 14 are imposed.

III. PAIRING CORRELATIONS

We now focus on particle-antiparticle mixing resulting from possible nonzero pairing correlations 17. These are discarded in most existing treatments of in-medium neutrino propagation (see e.g. 19, 21), based on the argument that, in the free theory, they undergo rapid oscillations on a time scale \( \sim 1/|\epsilon_{i,q} + \epsilon_{j,q}| \), with \( \epsilon_{i,q} = (q^2 + m_i^2)^{1/2} \) the (anti)particle energy, and thus average to zero on the typical time scales of interest for, e.g., neutrino flavor conversion. As we shall see below, this argument must be reconsidered in an interacting theory since such pairs generally receive contributions from the (anti)neutrino densities \( \rho \) and \( \bar{\rho} \). In particular, this occurs when the medium with which neutrinos interact is inhomogeneous and/or anisotropic.

In the following, we consider the case of a spatially homogeneous system and we take the ultrarelativistic (massless) limit for neutrinos since the role of such correlations is not controlled by the neutrino mass. Nonrelativistic corrections are discussed in Appendix A. The spinors appearing in 12-14 do not depend on the mass/flavor index. We first discuss the Dirac case and give the necessary modifications for the Majorana case.

A. Evolution equations for homogeneous systems in the ultrarelativistic limit

In the ultrarelativistic limit, and assuming Standard Model V-A interactions, it is sufficient to restrict oneself to the subset of two-point correlators in (7)-(10) involving negative helicity particle or positive helicity antiparticle operators. For spatially homogeneous systems
where the dot now involves a simple matrix product in mass/flavor indices, which we have left implicit here. Our convention for the signs of momenta in \([18-50]\) is such that all quantities appearing in the above evolution equations involve the same momentum \(\vec{q}^\prime\).

These equations can be conveniently rewritten in terms of the \(2N_f \times 2N_f\) matrices

\[
\mathcal{H}(t, \vec{q}) = \begin{pmatrix} \Gamma^{\nu\bar{\nu}}(t, \vec{q}) & \Gamma^{\bar{\nu}\nu}(t, \vec{q}) \\ \Gamma^{\bar{\nu}\nu}(t, \vec{q}) & \Gamma^{\nu\bar{\nu}}(t, \vec{q}) \end{pmatrix}
\]

and

\[
\mathcal{R}(t, \vec{q}) = \begin{pmatrix} \rho(t, \vec{q}) & \kappa(t, \vec{q}) \\ \kappa^{\dagger}(t, \vec{q}) & 1 - \bar{\rho}(t, \vec{q}) \end{pmatrix}
\]

as

\[
i \dot{\mathcal{R}}(t, \vec{q}) = [\mathcal{H}(t, \vec{q}), \mathcal{R}(t, \vec{q})].
\]

The corresponding evolution equations for Majorana neutrinos can be readily obtained from the previous ones following the discussion of Sec\(\[15\].\) In the ultrarelativistic limit considered here, with \(V-A\) interactions, one easily checks that the components of the extended mean-field Hamiltonians for Dirac and Majorana neutrinos coincide: \(\hat{H}_M(t, \vec{q}) = \hat{H}(t, \vec{q})\). The evolution equations for Majorana neutrinos thus take the same form as above with the replacements \(\rho(t, \vec{q}) \rightarrow \rho_M(t, \vec{q})\), \(\bar{\rho}(t, \vec{q}) \rightarrow \bar{\rho}_M(t, \vec{q})\), and \(\kappa(t, \vec{q}) \rightarrow \kappa_M(t, \vec{q})\). Here, \(\rho_M\) describes the density of “particles” (negative helicity states), \(\bar{\rho}_M\) the density of “antiparticles” (positive helicity states), and \(\kappa_M\) the “particle-antiparticle” pair correlations.

The first line of both Eqs.\(\[61, 62\]corresponds to those usually considered in most existing treatment of in medium neutrino propagation, which neglect the pair correlator \(\kappa\). However, one observes, from Eq.\(\[63\]that

\[\text{Note that for spatially homogeneous systems in the mean-field approximation there are infinitely many conserved quantities, one for each Fourier mode, as follows from tr } \mathcal{R}(t, \vec{q}) = 0, \text{ which implies that } \rho_M(t, \vec{q}) - \bar{\rho}_M(t, \vec{q}) = \text{const.} \]
the latter is sourced both by the particle and antiparticle densities $\rho$ and $\bar{\rho}$ and by the off-diagonal component $\Gamma^{\nu\nu}$ of the mean-field Hamiltonian \[64\]. One should thus reconsider the usual argument described previously for the neglect of pair correlations since these source terms have no reason to be rapidly oscillating. If the particle-antiparticle coupling $\Gamma^{\nu\nu}$ or $\Gamma^{\nu\bar{\nu}}_M$ for Majorana $\nu$ is nonzero, pair correlations can be generated through Eq. \[63\] and have a nontrivial backreaction on the time-evolution of the normal densities $\rho$ and $\bar{\rho}$. We now discuss the explicit form of the mean-field Hamiltonian \[63\] and the conditions for such a nontrivial particle-antiparticle mixing term.

**B. Mean-field Hamiltonian in a dense anisotropic environment**

We consider a typical astrophysical environment, e.g., a core-collapse supernova, with a dense gas of self-interacting (anti)neutrinos in a background of electrons and nucleons\[1\]. For the sake of the argument, we assume (local) spatial homogeneity, although this idealization should be released for simulations in realistic geometries. We assume an unpolarized and electrically neutral but, otherwise, possibly anisotropic matter background while we treat the relativistic neutrino gas in full generality. Matter anisotropies are important in multidimensional supernovæ simulations \[13\]. Neutrino anisotropies have been shown to potentially play an important role for neutrino flavor conversion \[8\].

A new ingredient of the present discussion is that, contrarily to previous treatments, we keep track of the neutrino-antineutrino pair correlations in the expression of the mean-field Hamiltonian; Eqs. \[1\] or \[63\]. To this aim we consider a regime where an extended mean-field approximation is still applicable and explicit collisions are neglected. Strictly speaking, in the typical situation of interest here, where neutrino opacity is nonnegligible, one should also include collisions. However, the mean-field approximation is simple enough to be manageable, allowing us to pinpoint the potential role of neutrino-antineutrino pair correlations and the necessary ingredients for their presence.

\[7\] One can generalize the present treatment to take into account possible external (e.g., magnetic) fields, other type of particles in the background and/or non-standard interactions.

1. Vacuum and matter contributions

Let us first consider the contributions to the kernel $\Gamma_{ij}(t, \vec{x})$ from the free Hamiltonian, i.e., $(-i\gamma^\mu \nabla + m_i)\delta_{ij}$, and from the neutral and charged current interactions with the matter background. The former does not lead to any off-diagonal particle-antiparticle mixing term in \[64\]: $\Gamma^{\nu\nu}_\text{vac}(t, q) = 0$ and

\[71\]

with $h^0(q) = \text{diag}(\epsilon_{e,q})$ in the mass eigenstate basis.

The matter contribution only concerns active neutrino species and is diagonal in the flavor basis. The neutral current interactions with the electron, proton and neutron backgrounds are flavor insensitive and give the mean-field kernel

\[70\]

where $\phi_f$ represent the field associated to the particle $f$ and where $c_f^\nu$ and $c_A^\mu$ are the corresponding vector and axial coupling constants. Assuming an unpolarized background with no antiparticles, the medium average in \[68\] is easily computed as \[89\]

\[72\]

where we defined the four-velocity density for the particle of type $f$ as

\[73\]

with $v_f^\mu = p^\mu / E_f^\nu$ and $E_f^\nu = \sqrt{p^2 + m_f^2}$. The assumption of vanishing electric charge current, i.e., $J_{e}^\nu(t) + J_{p}^\mu(t) = 0$, guarantees that the contribution from protons and electrons to the neutral current mean-field Hamiltonian cancel each other since $c_f^\nu = -c_A^\nu$.

Finally, the charged current contribution from electrons is of the same form as Eq. \[88\] with $c_V = c_A = 1$ and yields

\[74\]
Using $c_3^n = -1/2$, the total contribution from the matter background thus reads, in the flavor basis,
\[
\tilde{\Gamma}^{\text{mat}}_{\alpha\beta}(t) = \frac{G_F}{\sqrt{2}} \delta_{\alpha\beta} \gamma^\mu (1 - \gamma_5) \left[ J^\mu_\alpha(t) \delta_{\alpha\beta} - \frac{1}{2} J^0_\alpha(t) \right].
\]

2. Neutrino self-interactions

The neutrino self-interaction mean-field Hamiltonian can be obtained from the Standard Model neutral current interaction term in the contact interaction approximation
\[
H^{\text{int}}_\text{self} = \frac{G_F}{4\sqrt{2}} \sum_{\alpha,\beta} \int d^3x j^\mu_\alpha(t, \vec{x}) j^\beta_\mu(t, \vec{x}),
\]
where $j^\mu_\alpha(t, \vec{x}) = \bar{\psi}_\alpha(t, \vec{x}) \gamma^\mu (1 - \gamma_5) \gamma^\rho (1 - \gamma_5) \psi_\alpha(t, \vec{x})$. Note that, thanks to the flavor sums in (73), the neutral current Hamiltonian takes the very same form in the mass eigenstate basis. This is useful when one is interested in keeping track of the neutrino masses in the mean-field evolution equations; see Sec. IV and Appendix A. Although this is unimportant in the present case, where we take the massless limit, we keep working in the mass eigenstate basis for notational consistency throughout the paper. The mean-field, approximation to Eq. (73) can be simply obtained by replacing quadrilinear products of field operators by bilinear ones using a Wick-like formula and using the Fierz theorem to reorganize spinorial products \[10\]. This leads to an expression of the form \[11\] with
\[
\tilde{\Gamma}^{\text{self}}_{ij}(t) = \frac{G_F}{2\sqrt{2}} \gamma^\mu (1 - \gamma_5) (\bar{\psi}_j(t, \vec{x}) \gamma^\mu (1 - \gamma_5) \psi_i(t, \vec{x})),
\]
written here directly in the mass basis.\[8\]

The mean-field kernel \[12\] is easily expressed in terms of the (anti)particle densities and pair correlations \(7\)–\[10\]. In the homogenous case, the relevant spinor products are
\[
\bar{u}(\bar{p}) \gamma^\mu (1 - \gamma_5) u(\bar{p}) = \bar{v}(\bar{p}) \gamma^\mu (1 - \gamma_5) v(\bar{p}) = 2n^\mu(\bar{p})
\]
and
\[
\bar{v}(-\bar{p}) \gamma^\mu (1 - \gamma_5) u(\bar{p}) = 2\epsilon^\mu(\bar{p}).
\]

Here, we have introduced the light-like four-vectors
\[
n^\mu(\bar{p}) = \left( \frac{1}{\bar{p}} \right) \quad \text{and} \quad \epsilon^\mu(\bar{p}) = \left( \frac{0}{\epsilon_p} \right),
\]
where $\bar{p} = \bar{p}/p$ denotes the unit vector in the direction of $\bar{p}$ and the pair of complex vectors $(\epsilon_p, \epsilon_p^*)$ spans the plane orthogonal to $\bar{p}$, with $\epsilon_p \cdot \epsilon_p = 0$, $\epsilon_p \cdot \epsilon_p^* = 2$. The four-vectors \[77\] satisfy
\[
n^\mu(\bar{p})n_\mu(\bar{p}) = n^\mu(\bar{p})\epsilon_\mu(\bar{p}) = \epsilon^\mu(\bar{p})\epsilon_\mu(\bar{p}) = 0 \quad \text{(78)}
\]
and
\[
\epsilon^\mu(\bar{p})\epsilon^*_\mu(\bar{p}) = -2. \quad \text{(79)}
\]

Note also that $\epsilon_\mu(-\bar{p}) = \epsilon^*_\mu(\bar{p})$. We thus obtain, for the kernel \[74\], leaving the mass/flavor indices implicit
\[
\tilde{\Gamma}^{\text{self}}(t) = \frac{G_F}{\sqrt{2}} \gamma^\mu (1 - \gamma_5) \int_{\vec{p}} \left\{ n^\mu(\bar{p}) \left[ \rho(t, \bar{p}) - \bar{p} \cdot \bar{p} \right] + \epsilon^\mu(\bar{p}) \kappa(t, \bar{p}) + \epsilon^*_\mu(\bar{p}) \kappa^*(t, \bar{p}) \right\},
\]
(80)

3. Total mean-field Hamiltonian

The components \[57\]–\[60\] of the total mean-field Hamiltonian \[61\] are readily obtained using \[74\] and \[76\]. Collecting the contributions from the previous subsections, we finally get
\[
\Gamma^{\mu\nu}(t, \bar{q}) = S(t, q) - \bar{q} \cdot \bar{V}(t) \quad \text{(81)}
\]
\[
\Gamma^{\nu\bar{q}}(t, \bar{q}) = \bar{S}(t, q) + \bar{q} \cdot \bar{V}(t) \quad \text{(82)}
\]
\[
\Gamma^{\nu\bar{q}}(t, \bar{q}) = -\epsilon^*_q \cdot \bar{V}(t), \quad \text{(83)}
\]
with the $N_f \times N_f$ scalar and vector matrices
\[
S(t, k) = h^0(t, k) + h^{\text{mat}}(t) + \sqrt{2} G_F \int_{\vec{p}} \ell(t, \bar{p}) \quad \text{(84)}
\]
\[
\bar{S}(t, k) = -h^0(t, k) + h^{\text{mat}}(t) + \sqrt{2} G_F \int_{\vec{p}} \ell(t, \bar{p}) \quad \text{(85)}
\]

\[9\] In terms of an oriented triad of real orthogonal unit vectors $(\hat{p}, \hat{p}_0, \hat{p}_0)$, for instance the standard unit vectors associated to $\bar{p}$ in spherical coordinates, one has $\epsilon_p = \hat{p}_0 - i\hat{p}_0$.

\[10\] We use the fact that, in the vacuum, $\langle 0 | \psi^\mu (1 - \gamma_5) \psi |0 \rangle = \int_{\vec{p}} \bar{\psi}(\bar{p}) \gamma^\mu (1 - \gamma_5) \psi(\bar{p}) = 0$ by Lorentz symmetry (this requires a Lorentz invariant ultraviolet regulator).
\[ \vec{V}(t) = \vec{V}^{\text{mat}}(t) + \sqrt{2} G_F \int_{\vec{p}} \left\{ \hat{\rho}(t, \vec{p}) + \hat{c}_p \kappa(t, \vec{p}) + \hat{c}_p^* \kappa^\dagger(t, \vec{p}) \right\}, \]

where we defined
\[ \ell(t, \vec{q}) = \rho(t, \vec{q}) - \bar{\rho}(t, -\vec{q}). \]

The scalar and vector matter contributions in the active neutrino sector read, in the flavor basis,
\[ h^{\text{mat}}_{\alpha\beta}(t) = \sqrt{2} G_F \delta_{\alpha\beta} \left[ N_e(t) \delta_{\alpha e} - \frac{1}{2} N_\nu(t) \right], \]
\[ \vec{V}^{\text{mat}}_{\alpha\beta}(t) = \sqrt{2} G_F \delta_{\alpha\beta} \left[ \vec{J}_e(t) \delta_{\alpha e} - \frac{1}{2} \vec{J}_\nu(t) \right], \]

with the particle number and velocity densities \( \vec{v}_f = \vec{p}/E_p^f \),
\[ N_f(t) = 2 \int_{\vec{p}} \rho_f(t, \vec{p}) \quad \text{and} \quad \vec{J}_f(t) = 2 \int_{\vec{p}} \vec{v}_f \rho_f(t, \vec{p}). \]

Our final expression for the mean-field Hamiltonian in its \( 2N_f \times 2N_f \) matrix form thus reads
\[ \mathcal{H}(t, \vec{q}) = \begin{pmatrix} S(t, q) - \hat{q} \cdot \vec{V}(t) & -\hat{c}_p^* \cdot \vec{V}(t) \\ -\hat{c}_p \cdot \vec{V}(t) & S(t, q) + \hat{q} \cdot \vec{V}(t) \end{pmatrix} + \mathcal{H}_M(t, \vec{q}). \]  

We stress that nontrivial, off-diagonal particle-antiparticle mixing occur whenever the matrix \( \vec{V}(t) \neq 0 \).

Clearly, this requires anisotropic matter and/or neutrino backgrounds, as we already pointed out. We note finally that the neutron contribution to \( h^{\text{mat}}, \) Eq. \( 85 \), gives a term proportional to \( \mathbb{I}_{2N_f \times 2N_f} \) in the full mean-field Hamiltonian \( 91 \) and can thus be discarded in the evolution equation \( 96 \). This is, however, not the case for the neutron contribution to the anisotropic term \( \vec{V}^{\text{mat}}, \) Eq. \( 89 \), which gives a nonzero off-diagonal neutrino-antineutrino coupling. It is easy to check explicitly that the corresponding Hamiltonian for Majorana neutrinos in the ultrarelativistic limit coincide with Eq. \( 11 \): \( \mathcal{H}_M(t, \vec{q}) = \mathcal{H}(t, \vec{q}) \), as announced above.

We end this section by comparing Eq. \( 11 \) to the standard evolution Hamiltonian employed in studies of neutrino propagation in a supernova enveloppe. Assuming outward propagation of both particles and antiparticles from the neutrino sphere, such as in the bulb model \( 41 \), it is justified to set \( \kappa \to 0 \) and \( \Gamma^{\nu\bar{\nu}} \to 0 \) in Eqs. \( 81 \)-\( 83 \). Assuming an isotropic matter background such that \( \vec{J}_f(t) = 0 \), one recovers the usual Hamiltonian \( 94 \):\n\[ \Gamma^{\nu\nu}(t, \vec{q}) \big|_{\kappa \to 0} = h^0(q) + h^{\text{mat}}(t) + h^{\nu\nu}(t, \vec{q}), \]

with \( h^{\nu\nu}(t, \vec{q}) = \sqrt{2} G_F \int_{\vec{p}} (1 - \hat{q} \cdot \hat{p}) \ell(t, \vec{p}). \)

We emphasize again that when the neutrino opacity cannot be neglected, simply assuming that \( \kappa \to 0 \) is not a consistent approximation. Indeed, in such cases the particle-antiparticle mixing term in \( 91 \) is nonzero:
\[ \Gamma^{\nu\bar{\nu}}(t, \vec{q}) \big|_{\kappa \to 0} = -\sqrt{2} G_F \int_{\vec{p}} (\hat{c}_p^* \cdot \hat{c}_p) \ell(t, \vec{p}), \]

from which it follows that nonzero pair correlations can be generated, as discussed previously.

Pair correlations were first discussed in \( 17, 40 \) in the context of in-medium neutrino propagation. The evolution equations derived there have the same structure as \( 91 \)-\( 93 \). However, the class of mean-field dynamics studied is not completely general in that it implements particle and antiparticle number conservation separately and some terms included in the present general, fully relativistic treatment are missing. As a consequence, the evolution Hamiltonians in the particle and antiparticle sectors obtained in \( 17, 40 \) are identical to \( 92 \)-\( 93 \), whereas the particle-antiparticle mixing term, referred to as the pairing (or abnormal) mean-field \( \Delta \) in these articles, is given by
\[ \Delta(t, \vec{q}) = -\sqrt{2} G_F \int_{\vec{p}} (\hat{c}_p^* \cdot \hat{c}_p) \kappa(t, \vec{p}). \]

An obvious consequence of isotropy is that the correlators \( \rho(t, \vec{q}), \) \( \hat{\rho}(t, \vec{q}) \) and \( \kappa(t, \vec{q}) \) only depend on \( q = |\vec{q}| \). Isotropy further implies that \( \kappa(t, q) = -\kappa^*(t, q) \).

For instance, this is needed to recover \( \langle \psi_i \gamma^0 (1 - \gamma^5) \psi_j \rangle = 0 \).

11 It follows from the definitions \( 60 \) and \( 69 \) that both the correlator \( \kappa \) and the particle-antiparticle mixing \( \Gamma^{\nu\bar{\nu}} \) require particles and antiparticles with (nearly) opposite momenta. For outward free streaming, the spinors \( u(q) \) and \( v(\bar{q}) \) in Eq. \( 69 \) should be understood to be nonzero only for outward momenta.

12 With our conventions the antineutrino number density matrix is \( \bar{\rho}(t, -\vec{q}) \) and the corresponding Hamiltonian is thus obtained as \( \Gamma^{\nu\bar{\nu}}(t, -\vec{q}) \big|_{\kappa \to 0} = -h^0(q) + h^{\text{mat}}(t) + h^{\nu\nu}(t, \vec{q}) \), in accordance with known results \( 14, 41 \).

13 In particular, contrarily to what happens in the general case discussed here, the limit \( \kappa \to 0 \) is a consistent solution of the evolution equations derived in \( 17, 30 \).
This corresponds to keeping only the third term in the general mean-field expression \[^{[20]}\].

### IV. HeliCITY COHerence

We now turn to the study of neutrino-antineutrino mixing arising from nontrivial helicity coherence. These are encoded in the nondiagonal helicity components of the density correlators, e.g., \(\rho_{-,+}(t, \vec{q})\) or \(\bar{\rho}_{+,+}(t, \vec{q})\). Strictly speaking, these are related to neutrino-antineutrino mixing only in the case of Majorana neutrinos. For Dirac fields, such correlators involve a sterile component. Diagonal and nondiagonal helicity components are coupled through the nonvanishing neutrino mixings only in the case of Majorana neutrinos. For Dirac fields, such correlators involve a sterile component. Diagonal and nondiagonal helicity components are coupled through the nonvanishing neutrino mixings only in the case of Majorana neutrinos.

For simplicity, we focus on helicity coherence throughout this section and set the pair correlations from the previous section. For simplicity, we focus on helicity coherence throughout this section and set the pair correlations from the previous section.

#### A. Mass corrections to the evolution equations

In a general spatially homogeneous system, the evolution equations for the equal-time two-point correlators keep the general structure \[^{[21]}\quad^{[22]}\] where all quantities are to be understood as \(2N_f \times 2N_f\) matrices in mass/flavor and helicity space. For instance, keeping the mass/flavor indices implicit, the generalized particle and antiparticle densities have the following helicity structure\[^{[15]}\]:

\[
\rho(t, \vec{q}) \to \begin{pmatrix}
\rho_{-,+}(t, \vec{q}) & \rho_{+,+}(t, \vec{q}) \\
\rho_{+,+}(t, \vec{q}) & \rho_{++,+}(t, \vec{q})
\end{pmatrix}
\equiv
\begin{pmatrix}
\rho(t, \vec{q}) & \zeta(t, \vec{q}) \\
\zeta(t, \vec{q}) & \tilde{\rho}(t, \vec{q})
\end{pmatrix},
\]

and

\[
\bar{\rho}(t, \vec{q}) \to \begin{pmatrix}
\bar{\rho}_{-,+}(t, \vec{q}) & \bar{\rho}_{+,+}(t, \vec{q}) \\
\bar{\rho}_{+,+}(t, \vec{q}) & \bar{\rho}_{++,+}(t, \vec{q})
\end{pmatrix}
\equiv
\begin{pmatrix}
\bar{\rho}(t, \vec{q}) & \bar{\zeta}(t, \vec{q}) \\
\bar{\zeta}(t, \vec{q}) & \bar{\tilde{\rho}}(t, \vec{q})
\end{pmatrix},
\]

where the last equalities define our notation for the helicity correlators. For completeness we recall the definitions

\[
\rho_{ij,hh}(t, \vec{q}) = \langle a^\dagger_i(t, \vec{q}) \rho_{hh}(t, \vec{q}) a_j(t, \vec{q}) \rangle
\]

\[
\bar{\rho}_{ij,hh}(t, -\vec{q}) = \langle b^\dagger_i(t, \vec{q}) \bar{\rho}_{hh}(t, \vec{q}) b_j(t, \vec{q}) \rangle.
\]

For instance, the helicity coherence term in the particle sector is \(\zeta_{ij}(t, \vec{q}) = \langle a^\dagger_i(t, \vec{q}) + a_i(t, \vec{q}) \rangle\), etc. Note that we use the same notation as in the previous section for the correlators \(\rho_{ij}(t, \vec{q}) = \langle a^\dagger_i(t, \vec{q}) - a_i(t, \vec{q}) \rangle\) and \(\bar{\rho}_{ij}(t, -\vec{q}) = \langle b^\dagger_i(t, \vec{q}) + b_i(t, \vec{q}) \rangle\).

Similarly, the helicity components of the mean-field Hamiltonians in the particle and antiparticle sectors, i.e.,

\[
\Gamma_{ij,hh}(t, \vec{q}) = \bar{u}_i(q, h) \bar{\Gamma}_{ij}(t) u_j(q, h^*)
\]

\[
\bar{\Gamma}_{ij,hh}(t, \vec{q}) = \bar{v}_i(q, -h) \bar{\Gamma}_{ij}(t) v_j(q, -h^*),
\]

can be gathered in a \(2N_f \times 2N_f\) matrix form as

\[
\Gamma_{\omega
\nu}(t, \vec{q}) \to \begin{pmatrix}
\Gamma_{\omega
\nu}^{\rho-\rho-}(t, \vec{q}) & \Gamma_{\omega
\nu}^{\rho-\rho+}(t, \vec{q}) \\
\Gamma_{\omega
\nu}^{\rho+\rho-}(t, \vec{q}) & \Gamma_{\omega
\nu}^{\rho+\rho+}(t, \vec{q})
\end{pmatrix}
\equiv
\begin{pmatrix}
\Phi(t, \vec{q}) & \bar{\Phi}(t, \vec{q}) \\
\bar{\Phi}(t, \vec{q}) & \Phi(t, \vec{q})
\end{pmatrix}
\]

and

\[
\Gamma_{\omega\bar{\nu}}(t, \vec{q}) \to \begin{pmatrix}
\Gamma_{\omega\bar{\nu}}^{\bar{\rho}-\bar{\rho}-}(t, \vec{q}) & \Gamma_{\omega\bar{\nu}}^{\bar{\rho}-\bar{\rho}+}(t, \vec{q}) \\
\Gamma_{\omega\bar{\nu}}^{\bar{\rho}+\bar{\rho}-}(t, \vec{q}) & \Gamma_{\omega\bar{\nu}}^{\bar{\rho}+\bar{\rho}+}(t, \vec{q})
\end{pmatrix}
\equiv
\begin{pmatrix}
\bar{\Phi}(t, \vec{q}) & \Phi(t, \vec{q}) \\
\Phi(t, \vec{q}) & \bar{\Phi}(t, \vec{q})
\end{pmatrix},
\]

where, again, the second equalities define our notations.

Discarding pair correlations, the evolution equations read

\[
i\dot{\rho}(t, \vec{q}) = [\Gamma_{\omega\nu}(t, \vec{q}), \rho(t, \vec{q})]
\]

\[
i\dot{\bar{\rho}}(t, \vec{q}) = [\Gamma_{\omega\bar{\nu}}(t, \vec{q}), \bar{\rho}(t, \vec{q})].
\]

### B. Mass corrections to the mean-field Hamiltonian

We compute the \(O(m/q)\) corrections to the interaction part of the mean-field Hamiltonian. The matter kernel \[^{[23]}\] is not modified as compared to previous section, whereas the contribution \[^{[24]}\] from neutrino self-interaction receive corrections from the off-diagonal helicity components of the various density matrices. A straightforward calculation of spinor products (see Appendix \[^{[25]}\]) yields

\[
\Gamma_{\text{self}}(t) = \frac{G_F}{\sqrt{2}} \frac{1}{1 - \gamma_5} \int \frac{d^4p}{p^2} \left\{ n_p(\tilde{p}) \left[ \rho(t, \vec{p}) - \bar{\rho}(t, -\vec{p}) \right] - e^{-i\vec{p}\cdot\vec{r}} \epsilon_\mu(\tilde{p}) \Omega(t, \vec{p}) \frac{m}{2p^2} \frac{m}{2p^2} \left( \epsilon_\mu^*(\tilde{p}) \Omega(t, \vec{p}) \right) \right\},
\]

\[(106)\]
where $\phi_p$ is the polar angle of the vector $\hat{p}$ in spherical coordinates. Here, $m$ denotes the neutrino mass matrix and we introduced the combination

$$\Omega(t, \vec{p}) = \zeta(t, \vec{p}) + \bar{\zeta}(t, -\vec{p}).$$  \hspace{1cm} (107)

Finally, we obtain, for the components of the mean-field Hamiltonians $H(t, \vec{q})$, $\Phi(t, \vec{q})$, and $\bar{\Phi}(t, \vec{q})$ for the interaction terms $O(m^2/q^2)$ the expressions

$$H(t, \vec{q}) = S(t, \vec{q}) - \hat{q} \cdot \vec{V}(t) - \hat{q} \cdot \vec{V}_m(t)$$

$$\Phi(t, \vec{q}) = e^{i\phi_v} \hat{q} \cdot \vec{V}(t) \frac{m}{2q}$$

$$\bar{\Phi}(t, \vec{q}) = h^0(q),$$

and

$$\tilde{H}(t, \vec{q}) = \frac{m^2}{2q}.$$  \hspace{1cm} (110)

where $S(t, \vec{q})$, $\tilde{S}(t, \vec{q})$ and $\vec{V}(t)$ have been defined in Eqs. \[104\], \[105\], and \[106\] respectively and where the mass correction to the vector component of the mean-field Hamiltonians reads

$$\vec{V}_m(t) = -\sqrt{2} G_F \int_\vec{p} \left\{ e^{-i\phi_v} \epsilon_p \Omega(t, \vec{p}) \frac{m}{2p} + \text{h.c.} \right\}.$$  \hspace{1cm} (114)

As expected, the off-diagonal terms in the particle and antiparticle Hamiltonians, $\Phi$ and $\bar{\Phi}$, are proportional to the neutrino masses and the different helicity sectors are decoupled in the ultrarelativistic limit.

C. Majorana neutrinos

As before, the treatment of Majorana neutrinos closely follows that of Dirac neutrinos. One introduces a similar matrix in helicity as in Eqs. \[111\] and \[112\] where $\rho_M(t, \vec{q}) = \rho_M^T(t, -\vec{q})$ and $\bar{\rho}_M(t, \vec{q}) = -\bar{H}_M^T(t, -\vec{q})$; see Eqs. \[111\] and \[112\]. We thus write

$$\rho_M(t, \vec{q}) \rightarrow \begin{pmatrix} \rho_M(t, \vec{q}) & \zeta_M(t, \vec{q}) \\ \zeta_M^*(t, \vec{q}) & \rho_M^T(t, -\vec{q}) \end{pmatrix}$$  \hspace{1cm} (115)

and

$$\Gamma_{\nu\nu}^\nu_M(t, \vec{q}) \rightarrow \left( \begin{array}{cc} H_M(t, \vec{q}) & \Phi_M(t, \vec{q}) \\ \Phi_M^T(t, \vec{q}) & -\bar{H}_M^T(t, -\vec{q}) \end{array} \right).$$  \hspace{1cm} (116)

Using the results of the previous section together with the relations \[109\] and \[110\], we obtain

$$H_M(t, \vec{q}) = S(t, \vec{q}) - \hat{q} \cdot \vec{V}(t) - \hat{q} \cdot \vec{V}_m(t)$$

$$\bar{H}_M(t, \vec{q}) = \tilde{S}(t, \vec{q}) + \hat{q} \cdot \vec{V}(t) + \hat{q} \cdot \vec{V}_m(t)$$

$$\Phi_M(t, \vec{q}) = e^{i\phi_v} \hat{q} \cdot \vec{V}(t) \frac{m}{2q} + \frac{m}{2q} \vec{V}_m(t).$$

The evolution equations derived here are consistent with those obtained in Refs. \[21\] and \[27\], except for the mass correction \[113\] to the diagonal helicity components of the various evolution Hamiltonians, which has been neglected in these references. Note that, the couplings $\Phi$, $\tilde{\Phi}$ for Dirac neutrinos, or $\Phi_M$ for Majorana neutrinos, involve the vector component $\vec{V}(t)$ and thus vanish for isotropic systems, as pointed out in \[21\] and \[27\].

V. CONCLUSIONS

Investigating neutrino flavor evolution in dense astrophysical environments has numerous fascinating facets. In the present work we have derived the most general mean-field equations that are applicable in the case of inhomogeneous and anisotropic neutrino and matter backgrounds, for either massive Dirac or Majorana neutrinos. These encompass all mean-field evolution equations derived previously.

We have emphasized the presence of pairing correlations between neutrinos and antineutrinos and, for the Majorana case, also between pairs of neutrinos or antineutrinos. Such pair correlations, which correspond

$\footnote{Here, we only keep the corrections $O(m/q)$ in the interaction terms. The free contribution $h^0(q)$ can be expanded independently $h^0(q) \approx q + m^2/2q$. Note that the leading order kinetic term does not contribute to the evolution equations \[103\] and \[105\] and can thus be discarded. As noticed previously, this is not possible when pair correlations are present.}$

$\footnote{It is understood here that the expressions \[83\], \[84\], and \[85\] are evaluated at $\kappa = 0$; see Appendix \[A\] for the generalization to $\kappa \neq 0$.}$

$\footnote{In terms of the four-vectors $x_{1,2}^\mu$ introduced in \[21\] and \[27\], we have $e^{-i\phi_v} e^{\mu}\rho = x_{1,2}^\mu - i x_{1,2}^2$; see also Appendix \[A\].}$
to the fermionic analog of squeezed bosonic states, have been first discussed in the context of neutrino physics in [17, 30]. Our results generalize the evolution equation presented in these references to the case of a completely general, fully relativistic mean-field Hamiltonian.

We have also considered possible nontrivial helicity correlations due to the nonvanishing neutrino masses. These can be of either the normal or the pairing type. The former case corresponds to helicity coherence terms, which have been discussed in [21, 27, 42], whereas the latter have been first pointed out in [17]. We have treated such correlations by systematically including the first nonrelativistic corrections to the general mean-field evolution equations. When pair correlations are neglected, our results reproduce the evolution equations of Ref. [51, 52], from which we have derived kinetic equations taking proper account of pair correlations due to the nonvanishing neutrino masses. These can be of either the normal or the pairing type.

The former case corresponds to helicity coherence terms, whereas the latter has been neglected in [21, 27] as well as in the toy-model calculation of [42]. This approximation is justified as long the diagonal component is not small compared to the off-diagonal ones. However, in the opposite case, e.g., in a resonant regime such as considered in [42], the correction might not be negligible.

Finally, we have considered the full mean-field equations at leading order in the neutrino masses. This couples the effects of helicity coherence and pair correlations. Both effects may be of importance in dense anisotropic environments with nonzero neutrino opacity, e.g., the interior of the neutrinosphere in core-collapse supernovae. Both effects may be of importance in dense anisotropic environments with nonzero neutrino opacity, e.g., the interior of the neutrinosphere in core-collapse supernovae. We have also pointed out that nonzero coupling between normal (anti)neutrino densities and pair correlations occur at $O(m/q)$ even for isotropic systems. Future numerical investigations either in schematic models or in realistic simulations will reveal whether the various types of neutrino-antineutrino mixings can influence neutrino flavor evolution and possibly impact the nucleosynthetic outcomes in stellar environments, or the shock revival in supernova.

Although mean-field calculations are an important step to assess the possible role of unusual correlations, a more complete treatment of the dense astrophysical environments of interest here would require one to include collision terms. Formal kinetic equations including helicity coherence for neutrinos in anisotropic environments have been discussed in [21, 27], although the definite form of the collision term still needs to be derived. On the other hand, a general formalism to consistently derive kinetic equations taking proper account of pair correlations has been developed in [32, 33] for isotropic systems. This has been applied to a model system of fermionic and scalar fields with a Yukawa interaction in the context of lepto/baryogenesis. It would be of interest to apply these methods to neutrinos in situations of astrophysical interest.

Appendix A: Complete mean-field Hamiltonian at $O(m/q)$

We present the general mean-field equations for spatially homogeneous systems with both pair correlations and helicity coherence terms, including nonrelativistic corrections to the interaction Hamiltonian at first order in the neutrino masses. As explained in Sec. [LX] the equations of motion keep the same form as [61, 63], where each term is a $2N_f \times 2N_f$ matrix in mass/energy and helicity space. Equivalently, these can be written as Eqs. [60] where both the generalized density matrix and Hamiltonian are $4N_f \times 4N_f$ matrices. The diagonal blocks have been discussed in Sec. [LX] and Hamiltonian [64] are $4N_f \times 4N_f$ matrices. The diagonal blocks have been discussed in Sec. [LX] and Hamiltonian [64] are $4N_f \times 4N_f$ matrices. The diagonal blocks have been discussed in Sec. [LX] and Hamiltonian [64] are $4N_f \times 4N_f$ matrices. The diagonal blocks have been discussed in Sec. [LX] and Hamiltonian [64] are $4N_f \times 4N_f$ matrices. The diagonal blocks have been discussed in Sec. [LX] and Hamiltonian [64] are $4N_f \times 4N_f$ matrices. The diagonal blocks have been discussed in Sec. [LX] and Hamiltonian [64] are $4N_f \times 4N_f$ matrices. The diagonal blocks have been discussed in Sec. [LX] and Hamiltonian [64] are $4N_f \times 4N_f$ matrices. The diagonal blocks have been discussed in Sec. [LX] and Hamiltonian [64] are $4N_f \times 4N_f$ matrices. The diagonal blocks have been discussed in Sec. [LX] and Hamiltonian [64] are $4N_f \times 4N_f$ matrices. The diagonal blocks have been discussed in Sec. [LX] and Hamiltonian [64] are $4N_f \times 4N_f$ matrices. The diagonal blocks have been discussed in Sec. [LX] and Hamiltonian [64] are $4N_f \times 4N_f$ matrices. The diagonal blocks have been discussed in Sec. [LX] and Hamiltonian [64] are $4N_f \times 4N_f$ matrices.

for pairing correlations (the second equality defines our notation), and

$$\kappa(t, \vec{q}) \rightarrow \begin{pmatrix} \kappa_{--}(t, \vec{q}) & \kappa_{++}(t, \vec{q}) \\ \kappa_{+-}(t, \vec{q}) & \kappa_{-+}(t, \vec{q}) \end{pmatrix} = \begin{pmatrix} \kappa(t, \vec{q}) & \kappa(t, \vec{q}) \\ \kappa(t, \vec{q}) & \kappa(t, \vec{q}) \end{pmatrix},$$

(A1)

for the particle-antiparticle mixing terms in the Hamiltonian.

To discuss the explicit form of the mean-field Hamiltonian at $O(m/q)$, we introduce the following notation for the interaction part:

$$\tilde{\Gamma}^{\text{int}}(t) = \frac{1}{2} \gamma^\mu (1 - \gamma_5) \Sigma_\mu(t),$$

(A3)

where

19 These are the right-handed vector components of the neutrino self-energy in the mean-field approximation [21, 27].
self-interactions of the general form

\[ \Sigma_\mu(t) = \Sigma_{\mu}^{\text{mat}}(t) + \sqrt{2} G_F \int \{ n_\mu(\bar{p})[R(t, \bar{p}) - \bar{R}(t, -\bar{p})] + \epsilon_\mu(\bar{p})K(t, \bar{p}) + \epsilon_\mu^*(\bar{p})K^\dagger(t, \bar{p}) \}, \]  

(A4)

where \( R, \bar{R}, \) and \( K \) are combinations of the various two-point correlators. The matter contribution has been considered in Sec. III and reads, in the flavor basis, point correlators. The matter contribution has been considered in Sec. III and reads, in the flavor basis.

Using the spinor products recalled in Appendix B, a straightforward calculation of the correlator in Eq. (74) yields, at first nontrivial order in the neutrino mass matrix \( m \),

\[ R(t, \bar{p}) = \rho(t, \bar{p}) - e^{-i\phi_p} \mathcal{Z}(t, \bar{p}) \frac{m}{2p} + \frac{m}{2p} e^{i\phi_p} \mathcal{Z}^\dagger(t, \bar{p}) \]  

(A6)

\[ \bar{R}(t, \bar{p}) = \bar{\rho}(t, \bar{p}) + e^{-i\phi_p} \mathcal{Z}(t, \bar{p}) \frac{m}{2p} + \frac{m}{2p} e^{i\phi_p} \mathcal{Z}^\dagger(t, \bar{p}) \]  

(A7)

\[ K(t, \bar{p}) = \kappa(t, \bar{p}) - e^{-i\phi_p} \Omega(t, \bar{p}) \frac{m}{2p}. \]  

(A8)

where \( \Omega(t, \bar{p}) \) has been defined in (107).

1. Dirac case

Using, again, the spinor products of Appendix B and retaining systematically \( O(m/q) \) terms from the interaction parts, we finally obtain the components of the mean-field Hamiltonian as

\[ \Gamma_{-}(t, \bar{q}) = h^0(q) + n_\mu(\bar{q}) \Sigma^\mu(t) \]  

(A9)

\[ \Gamma_{+}(t, \bar{q}) = -e^{i\phi_q} n_\mu(\bar{q}) \Sigma^\mu_q(t) \frac{m}{2q} \]  

(A10)

\[ \Gamma_{-}(t, \bar{q}) = -e^{-i\phi_q} m \Sigma^\mu_q(t) \]  

(A11)

\[ \Gamma_{+}(t, \bar{q}) = h^0(q) \]  

(A12)

for the particle-particle sector,

\[ \Gamma_{-}(t, \bar{q}) = -h^0(q) \]  

(A13)

\[ \Gamma_{+}(t, \bar{q}) = -e^{-i\phi_q} m \Sigma^\mu_q(t) \frac{m}{2q} \]  

(A14)

\[ \Gamma_{-}(t, \bar{q}) = -e^{-i\phi_q} n_\mu(\bar{q}) \Sigma^\mu(t) \]  

(A15)

\[ \Gamma_{+}(t, \bar{q}) = -h^0(q) + n_\mu(\bar{q}) \Sigma^\mu(t) \]  

(A16)

for the antiparticle-antiparticle sector, and

\[ \Gamma_{-}(t, \bar{q}) = -e^{i\phi_q} n_\mu(\bar{q}) \Sigma^\mu(t) \frac{m}{2q} \]  

(A17)

\[ \Gamma_{+}(t, \bar{q}) = e^\phi q \Sigma^\mu(t) \]  

(A18)

\[ \Gamma_{-}(t, \bar{q}) = 0 \]  

(A19)

\[ \Gamma_{+}(t, \bar{q}) = -e^{-i\phi_q} m \Sigma^\mu_q(t) \]  

(A20)

for the particle-antiparticle mixing terms. The components of \( \Gamma^{\mu\nu} \) are obtained from (23). Here \( \Sigma^\mu_q(t) \) is obtained as Eq. (A11) evaluated at vanishing mass. This provides a complete set of evolution equations up to (and including) \( O(m/q) \) contributions, thus generalizing the equations presented in Sections III and IV. As mentioned there, couplings of the type \( \Gamma^{\mu\nu} \), \( \Gamma^{\mu\nu}_{++} \), and \( \Gamma^{\mu\nu}_{--} \) vanish for isotropic systems. Interestingly, we observe that the particle-antiparticle mixing terms \( \Gamma^{\mu\nu}_{-+} \) and \( \Gamma^{\mu\nu}_{+-} \) are nonzero in that case. These remarks hold equally for Majorana neutrinos as discussed below.

2. Majorana case

We obtain the independent component of the mean-field Hamiltonian for Majorana neutrinos from the results of the previous subsection by means of the relations (37) and (39). With our conventions (53, 56) for the momentum assignments in the case of spatially homogeneous systems, these become

\[ \Gamma^{\mu\nu}_M(t, \bar{q}) = \Gamma^{\mu\nu}(t, \bar{q}) - [\Gamma^{\mu\nu}(t, -\bar{q})]^T \]  

(A21)

\[ \Gamma^{\mu\nu}_M(t, \bar{q}) = \Gamma^{\mu\nu}(t, \bar{q}) - [\Gamma^{\mu\nu}(t, -\bar{q})]^T \]  

(A22)

where the transposition acts on both mass/flavor and helicity indices. Keeping in mind the different normalization of the free contribution to the Hamiltonian in the
Majorana case, i.e., $h^0(q) \to h^0(q)/2$, we obtain
\begin{align}
\Gamma_{\nu,\nu}^{\nu,-}(t, q) &= h^0(q) + n^\mu(q)\Sigma_\mu(t) \\
\Gamma_{\nu,\nu}^{\nu,-}(t, q) &= -e^{i\phi_h} e^{i\mu}(q) \left[ \Sigma_0(t) \frac{m}{2q} + \frac{m}{2q} \Sigma_0^\dagger(t) \right] \\
\Gamma_{\nu,\nu}^{\nu,+}(t, q) &= -e^{-i\phi_h} e^{i\mu}(q) \left[ \Sigma_0(t) \frac{m}{2q} + \frac{m}{2q} \Sigma_0^\dagger(t) \right] \\
\Gamma_{\nu,\nu}^{\nu,+}(t, q) &= h^0(q) - n^\mu(q)\Sigma_0^\dagger(t)
\end{align}
and where we have defined $(\varepsilon_{i,p} = \sqrt{p^2 + m_i^2})$
\[N_{p,h}^{i} = \sqrt{\frac{\varepsilon_{i,p} - hp}{2\varepsilon_{i,p}}} = \delta_{h-} + \frac{m}{2p} \delta_{h+} + O(m_i^2/p^2). \quad (B4)\]

Introducing the notation
\[\gamma_L^\mu = \gamma_L^1 - \gamma^5, \quad (B5)\]
the relevant bispinor products read
\begin{align}
\bar{u}_j(p, h)\gamma_L^\mu u_i(p, h) &= N_{p,h} j_i N_{p,h}^j n^\mu(-h\hat{p}) \approx n^\mu(\hat{p})\delta_{h-} \\
\bar{v}_j(p, h)\gamma_L^\mu u_i(p, h) &= N_{p,h} j_i N_{p,h}^j e^\mu(-h\hat{p}) \approx e^\mu(\hat{p})\delta_{h-}
\end{align}
and
\begin{align}
\bar{u}_j(p, h)\gamma_L^\mu u_i(p, h) &= -N_{p,h} j_i N_{p,h}^j e^{i\phi_h} e^\mu(-h\hat{p}) \\
&\approx -m_j e^{-i\phi_h} e^\mu(\hat{p})\delta_{h-} - \frac{m_1}{2p} e^{i\phi_h} e^\mu(\hat{p})\delta_{h+} \\
\bar{v}_j(p, h)\gamma_L^\mu u_i(p, h) &= -N_{p,h} j_i N_{p,h}^j e^{i\phi_h} n^\mu(-h\hat{p}) \\
&\approx -\frac{m_j}{2p} e^{-i\phi_h} n^\mu(\hat{p})\delta_{h-} - \frac{m_1}{2p} e^{i\phi_h} n^\mu(-\hat{p})\delta_{h+},
\end{align}
where the approximate expressions are valid up to relative corrections of order $m_i^2/p^2$. The other bispinor products needed in the text can be obtained from the relations
\begin{align}
\bar{v}_j(p, h)\gamma_L^\mu v_i(p, h') &= hh' \bar{u}_j(p, -h)\gamma_L^\mu u_i(p, -h') \quad (B10) \\
\bar{u}_j(p, h)\gamma_L^\mu v_i(p, h') &= [\bar{v}_i(-p, h')\gamma_L^\mu u_j(p, h)]^*. \quad (B11)
\end{align}
